The general reader will readily recognise plants of this group by the simple features first mentioned, and his ideas will be widened by a consideration of the examples mentioned below, which are arranged more or less in order of evolutionary progression from the simple and primitive to the complex and more recent. This, however, is impossible truly to represent in a linear series. The evolution of monocotyledons may be better understood by drawing a small circle to represent the primitive ancestral stock. Then from different parts of its periphery inscribe seven spirals of different colours and lengths, the first making one round of the circle and the last seven. The shortest (1st) marks pond-weeds, 2d palms, 3d grasses, 4th pine-apple, 5th lilies, 6th banana, 7th orchids. These spirals should then be connected with a few oblique, dotted cross-lines, especially between 3 and 4, 4 and 5, 5 and 6, and 6 and 7. On the spirals might be placed a succession of names representing genera both recent and fossil, and on the cross-lines names of intermediate connecting types. A scheme of this sort drawn on paper serves to impress one with the complex relationships introduced during the gradual evolution of modern monocotyledons, and is more truthful than a linear, radial, dendroid, or zigzag arrangement. The following are a representative set of monocotyledons: bur-reed, club-rush, screw-pine, naiad, grass-wrack, pond-weed, Triglochin, water-thyme, water-soldier, water-plantain, grasses, sedges, cotton-grass, aroids (e.g. Nile-lily, cuckoo-pint), duck-weed, palms, Restio, pipe-wort, spider-wort, Tillandsia, pine-apple, rush, lily, hyacinth, onion, tulip, Solomon's seal, New Zealand flax, Smilax, butcher's-broom, Yucca, Aloe, dragon-tree, parlour-palm, daffodil, snowdrop, Amaryllis, Agave, Alstremeria, Chinese yam, black bryony, Crocus, Gladiolus, Iris, banana, Manila hemp, ginger, Canna, Burmannia, and orchids.

To picture this series of plants in the mind's eye, together with the general characters already given, will afford the reader a basis for a more serious study of the monocotyledons as well as emphasise the vast importance of this group of plants to man and his food animals. Many of them provide the main source of supply for food, medicine, fibre, clothing, dwellings, &c., especially to people of warm regions, while others adorn the surface of the earth with beautiful flowers which raise and stimulate the higher nature of mankind.

The naturalist is prone to allow himself free rein when dealing with evolution. Here, however, this subject is introduced merely to indicate possible lines along which Nature has travelled: frankly, we have no exact knowledge of details. The annexed suggestions merely indicate how Nature may have proceeded in slowly evolving the more floristic monocotyledons from primitive types which were doubtless less floristic. First achlamydeous, acyclic flowers with an indefinite number of parts would be followed by more highly evolved kinds possessing dichlamydeous, pentacyclic, trimerous flowers. Going hand in hand with this rise of the floristic type would probably be the tendency for a higher specialisation from actinomorphic to zygo-

morphic flowers, in response to the general progression from the anemophilous to the entomophilous habit. Such progression in type would be accompanied by a gradual suppression of the floral axis, and hypogynous forms would evolve towards the epigynous type, and consequently the apocarpous towards the syncarpous. Such changes in plastic forms of plants have doubtless proceeded imperceptibly over so vast a period of the world's history that within the span of human record the existing plant population appears almost static. But besides the upward trend retrogressions have undoubtedly occurred. Plants like nations progress to a certain stage of complication or super-specialisation where the act of 'carrying on' becomes difficult or impossible in the face of a changing environment. Under such conditions modification of structure to match any necessary physiological variation must take place. Such structural modifications may be of greater or lesser complexity of body form (progression or retrogression), or, where plasticity has been insufficient for response, the type will suffer extinction, and a few examples of such have been handed down to us in the form of fossils. When considering the evolution of a group the foregoing, among other considerations, must be kept in view.

The seed of monocotyledons usually has a copious endosperm, and in germination, while the root from a rather small embryo grows vigorously, the cotyledon usually serves for the absorption of the endosperm; it consequently remains within the seed coat, and is commonly termed the haustorium or scutellum. The systematic study of the monocotyledons is most easily undertaken by clearly familiarising one's self with the Liliaceæ and their immediate allies, Amaryllidaceæ, Iridaceæ, &c.; and next by studying the progress of the floral specialisation, through Scitamineæ to its extreme in Orchidaceæ. Starting again from the lilies and their scarcely distinguishable allies, the rushes (Juncaceæ), we easily distinguish a series of still less floristic types, culminating in the sedges (Cyperaceæ) and grasses (Gramineæ), commonly grouped together as Glumifloræ. Another somewhat analogous line of change gives us the palms and Aroideæ, grouped as Spadicifloræ. These exhibit a connection with a lower type, the Pandanales, which include bur-reed, club-rush, and screw-pine. The Helobia (including Naiad, grass-wrack, pond-weed, as well as the Juncaginæ, Alismaceæ, and Hydrocharidaceæ) are also of special interest, as representing in some respects more primeval forms, and pointing back to a common ancestry with dicotyledons.

See VEGETABLE KINGDOM, and minor special articles; also Engler's *Pflanzenfamilien*, or the *Genera Plantarum* of Bentham and Hooker; Rendle, *Classification of Flowering Plants*, vol. i.; Warming and Potter, *Systematic Botany*; Wettstein, *Systematische Botanik*, Bd. ii.; Mrs Arber, *Monocotyledons* (1925); and the usual botanical text-books and floras.

Monod. ADOLPHE, an active theologian of the Reformed Church, was born in 1802 at Copenhagen, the son of a preacher, himself a native of Geneva. He studied at Geneva, and laboured as a preacher at Naples and Lyons, as a professor at Montauban, and again as a preacher in Paris until his death, 6th April 1856. He published sermons and many religious works which were widely popular.—His brother, FRÉDÉRIC, born 17th May 1794 at Monnaz, in the canton of Vaud, was thirty years a prominent pastor in Paris, and founded in 1849, together with Count Gasparin, the Free Reformed Church of France. He edited until his death, 30th December 1863, the *Archives du Christianisme*. See Adolphe's Life and Letters (Eng. trans. 1885).

Monodon. See NARWHAL.

Monodora, or CALABASH NUTMEG. See NUTMEG.

Monœcious, a term introduced by Linnæus to describe those plants which have the stamens and pistil in different flowers, but upon the same plant. Such plants formed one of the classes (*Monœcia*) of the Linnean system, but were obviously a specially artificial alliance, since that partial or complete separation of the sexes to which we apply the terms monœcious or diœcious respectively arises continually among the most unrelated plants.

Monogenists. See ETHNOLOGY.

Monogram (Gr.), a character composed of two or more letters of the alphabet, often interlaced with other lines, and used as a cipher or abbreviation of a name. A perfect monogram is one in which all the letters of the word are to be traced. They are found on early Greek coins, medals, and seals, and on the family coins of Rome, but not on the coins of the earlier Roman emperors. Constantine placed on his coins one of the earliest of Christian monograms, composed of the first and second letters of ΧΡΙΣΤΟΣ (*Christos*), a monogram which also appeared on the Labarum (q.v.; see also CROSS, and CONSTANTINE); we often find it combined with the first and last letters of the Greek alphabet (Rev. i. 8). Another well-known monogram is that of the name of Jesus, IHS, from the first three letters of ΙΗΣΟΥΣ. Popes, emperors, and kings of France during the middle ages were in the practice of using a monogram instead of signing their names. Fig. 1 represents that of Charlemagne, a perfect monogram, in which all the letters of *Karolus* can be traced. Painters and engravers in Germany and Italy have used monograms to a large extent as a means of distinguishing their works. Fig. 2 is the monogram of Albrecht Dürer. The first typographers made use of monograms or ciphers, a series of which, well known to the bibliographer, fixes the identity of the ancient editions, German, Italian, and English, from the invention of printing down to the middle or end of the 16th century. Those of William Caxton and Gaspard Philippe, an old Paris printer, will be found at BOOK. Potters' marks will be found at POTTERY.

Monolith. See STANDING-STONES.

Monomania. See INSANITY.

Monometallism. See BIMETALLISM.

Monomotopa, a 16th-century name for SE. Africa, apparently transferred in error from a prince to the country. See AFRICA (*Exploration*).

Monongahela, a river which rises in West Virginia and flows north to Pittsburgh, where it unites with the Alleghany to form the Ohio.

Mono'physites, Christians who hold that Christ has only *one* nature. See GREEK CHURCH.

Monopoli, a town of Southern Italy, on the Adriatic, 43 miles by rail NW. of Brindisi, with a cathedral, ancient walls, and a castle built in 1552 by Charles V.; pop. 30,000.

Monopoly is properly definable as the sole or exclusive right of selling or trading enjoyed by an individual or group of individuals. In its strict sense monopoly belongs to an economic era which has passed away. During mediæval times and the period that followed, exclusive rights prevailed in almost all departments. There were manorial

rights which circumscribed individual action. The city and the guild had their spheres of production and of trade more or less clearly defined, and more or less thoroughly recognised in practice. The central governments which arose on the ruins of the mediæval system continued to recognise such exclusive rights, sometimes conferring on favoured individuals the sole privilege of selling the most necessary articles of life, in other cases granting to great companies the monopoly of trade over immense regions of the world. It is with these instances that the name monopoly is most strictly associated in history. The last parliament of Elizabeth, held in 1601, pronounced an emphatic condemnation of the monopolies granted by that queen, and even she had to yield to the storm. Salt and coal were among the articles whose sale was thus subject to monopoly. One of the members made a sensation by asking: 'Is not bread among the number?' Curiously enough, the previous year saw the foundation by royal charter of the greatest of the companies which were based on the exclusive right of trade in an immense foreign market, the East India Company. The opposition to monopolies at home continued under the Stuarts, and their abolition may be regarded as one of the important results of the great parliamentary struggle of that time.

The spread of freedom has tended to the abolition of such monopolies, whether vested in individuals, in trade corporations, or in great companies engaged in foreign commerce. But, while the monopoly of law has so far passed away, new tendencies towards a monopoly of fact have been setting in. Under the prevalent system it is still the aim of the competitor to secure as far as possible the exclusive sale of the commodity in which he deals, either in the world-market or over a given portion of it; and when the single competitor is not strong enough to accomplish this, he seeks to attain his object by combination with a group of those engaged in the same business. The modern *trust* syndicate or union is the outcome of such efforts; and the great danger attendant on such gigantic combinations is the establishment of a monopoly injurious to society. The trust considered in its social and economic aspects offers a wide problem for discussion; there can be no doubt that it establishes or seeks to establish a monopoly of fact. For the recent growth of trusts in this sense in the United States and Britain, and attempts to control them by law, see ASSOCIATIONS, TRUSTS, AND CARTELS. In Australia the Federal Parliament endeavours to control by legislation attempts to monopolise trade to the detriment of the public. Some monopolies, as in tobacco, are retained by certain governments, but purely for revenue purposes. See also FARMERS-GENERAL.

Monorail. See RAILWAY.

Monotheism, the term usually employed to denote a belief in the unity of the Godhead, or belief in and worship of one God. It is thus the opposite of *Polytheism*. The doctrine of the Trinity is thought by some (e.g. the Unitarians) to be incompatible with the monotheism taught by Jesus Christ, and is therefore rejected as no part of His teaching. Mohammedans and Jews, of course, reject with vehemence the least approach to a Trinitarian conception of the Deity.

Monothelism (Gr. *monos*, 'single,' and *thelein*, 'to will'), the doctrine that Christ had only one will. It is a modification of Eutychianism. See EUTYCHES; GREEK CHURCH.

Monotremata (Gr. *monos*, 'single'; *trēma*, 'an opening'), the lowest order of mammals, sometimes called Prototheria and Ornithodelphia. There are but three living genera—Ornitho-

rhynchus (q.v.), Echidna (q.v.), and Proechidna, confined to Australia, Tasmania, and New Guinea, and very few fossils are known. The Monotremes differ in many ways from all other mammals, and some of their peculiarities may be called reptilian. Most striking of all are the two facts, that they are oviparous, and that the relatively large eggs (about 12 by 15 mm. when laid) show partial (or meroblastic) not total (or holoblastic) segmentation. The milk glands are without teats, and the milk oozes out by numerous apertures on the skin, whence it is licked off by the young. The cerebral hemispheres of the brain, smooth in Ornithorhynchus, convoluted in Echidna, are without the transverse bridge of fibres, the corpus callosum, which is characteristic of placental mammals. The pectoral girdle, which recalls that of some reptiles and amphibians, has a strong coracoid reaching the breast-bone, whereas in other mammals the coracoid is a mere process, fused to the shoulder-blade or scapula. There is a large T-shaped prosternum or 'interclavicle.' The hip-girdle shows marsupial or epipubic bones, as in marsupials. There are no hints of teeth in Echidnidae, and those of Ornithorhynchus last only until the animal is half-grown, when they are shed and replaced by horny pads. The heart, as compared with that of other mammals, is less differentiated in respect to the valve between the right auricle and the right ventricle. The temperature of the body is lower than usual (about 28° C.), and is notably variable. In other words, the 'warm-bloodedness,' characteristic of mammals and birds, is not quite perfect. The urinary and reproductive arrangements are peculiar, and, as the name monotreme suggests, there is one common terminal chamber, or cloaca, by which ureters, genital ducts, and food-canal communicate with the exterior. Monotremes might be briefly defined as oviparous mammals with meroblastic ova. Their nearest relationships are probably with the extinct Multituberculata. See F. E. Beddard, 'Mammalia,' *Cambridge Natural History*, vol. x. (1902).

Monreale, a city of Sicily, 5 miles SW. of Palermo. The 'royal mount,' from which it gets its name, is 1231 feet high, and on it stands the famous cruciform Norman cathedral (1176), which measures 333 by 132 feet, and within is entirely covered with mosaics. Pop. 27,000.

Monro, ALEXANDER, founder of the medical school of Edinburgh, styled *primus* to distinguish him from his son and successor, was born in London, September 8, 1697. His grandfather, Sir Alexander Monro, a colonel in the army of Charles II. at the battle of Worcester in 1651, was afterwards an advocate at the Scottish bar. Alexander studied at London under Hawksbee, Whiston, and Cheselden, at Paris under Bouquet, and at Leyden under Boerhaave, and after 1719 lectured at Edinburgh on anatomy and surgery. His lectures, with those of Alston on botany, led to the founding of the medical school, when Monro was appointed professor of Anatomy in 1721. He was received into the university in 1725. For forty years he lectured regularly on anatomy and surgery from October to May, students coming from all parts of Britain to hear him. Of the establishment of the Royal Infirmary of Edinburgh he was one of the two principal promoters, and he there delivered clinical lectures. In 1759 he resigned the anatomical chair to his youngest son, Dr Alexander Monro, but continued his clinical lectures at the Infirmary. His principal works are *Osteology* (1726), *Essay on Comparative Anatomy* (1744), *Observations Anatomical and Physiological* (1758), and an *Account of the Success of Inoculation of Smallpox in Scotland*

(1765). He died July 10, 1767. He was a Fellow of the Royal Society of London, and of various foreign societies. A collected edition of his works, with Life, was issued by his son (1781).

ALEXANDER MONRO, *secundus* (1733-1817), youngest son of the preceding, studied at Edinburgh, Berlin, and Leyden, and succeeded his father in the chair of Anatomy, and as secretary of the Royal Society of Edinburgh. He published works on the nervous system (1783), on the physiology of fishes (1785), and on the brain, the eye, and the ear (1797).—He again was succeeded by his son, ALEXANDER MONRO, *tertius* (1773-1859), who wrote on hernia, and on the stomach, and an *Anatomy of the Human Body* (4 vols. 1813).

Monroe, a city of Michigan, on the Raisin River, 2 miles by a ship-canal from Lake Erie, and 35 miles SSW. of Detroit, has tile, paper, flour, and other works; pop. 11,600.

Monroe, JAMES, fifth president of the United States, was born in Westmoreland county, Virginia, 28th April 1758, the descendant of a family of Scottish extraction which had emigrated to Virginia a century before. He entered William and Mary College at the age of eighteen, but soon threw aside his books, with a number of his fellow-students, to join the army under Washington. He was present at several battles, and was wounded at Trenton; he afterwards attained the rank of lieutenant-colonel as an aide-de-camp and military commissioner but was disappointed in his efforts to obtain a commission in a Virginia regiment, and attached himself to Jefferson, with whom he studied law. In 1782 he was elected to the assembly of Virginia and appointed one of the executive council. Next year he was returned to congress, where he sat for three years, and in 1785 was chairman of a committee whose report ultimately led to the conventions at Annapolis and Philadelphia in 1786 and 1787, at which the constitution of the United States was framed. Monroe himself was a member of the Virginia convention held to consider the ratification of the proposed constitution, which, along with Patrick Henry and other States' Rights men, he opposed, fearing the power and encroachment of the Federal government. He was a member of the United States senate from 1790 to 1794, and offered a determined opposition to Washington and the Federalists; yet the government appointed him to succeed Gouverneur Morris as minister to France, where he made himself very popular with the revolutionary government, until he was recalled in 1796 for displaying too decided French sympathies. On his return he published (1797) an attack on the executive for their treatment of him, and, although Washington himself, who had then retired, took no notice of it, the book brought on a bitter controversy and made Monroe the darling of the Democrats. He was governor of Virginia from 1799 to 1802, and then Jefferson sent him as an extra plenipotentiary to France, where in 1803 he and Robert R. Livingston effected the purchase of Louisiana (q.v.). The next four years were spent in less successful diplomacy at London and Madrid; he failed in his negotiations with Spain for the cession of Florida, whilst a treaty which he finally concluded with Great Britain provided neither against the impressment of American seamen nor for an indemnity for American losses by seizures at sea, and Jefferson refused to refer it to the senate. Monroe promptly returned home and drew up another defence, and the Virginians endorsed his conduct and policy by a third time electing him to the assembly. In 1811 he was again chosen governor of Virginia. In the same year Madison made him secretary of state; this

post he retained till 1817, and during 1814-15 he acted also as secretary of war.

In 1816 Monroe was elected president of the United States, and four years later he was re-elected almost unanimously; the acquisition of Florida from Spain (1819), and the settlement of the vexed question respecting the extension of slavery by the Missouri Compromise, by which, after the reception of Missouri as a slave-state, the institution was prohibited above the line of latitude 36° 30', helped to secure this result. His most popular acts, perhaps, were the recognition of the independence of the Spanish American republics, and the promulgation in a message to congress (1823) of what has since been called the 'Monroe Doctrine.' This utterance embodied the principle, 'in which the rights and interests of the United States are involved, that the American continents . . . are henceforth not to be considered as subjects for future colonisation by any European power. . . . With the existing colonies or dependencies of any European power we have not interfered, and shall not interfere. But with the governments who have declared their independence and maintained it, and whose independence we have . . . acknowledged, we could not view any interposition for the purpose of oppressing them, or controlling in any other manner their destiny, by any European power, in any other light than as the manifestation of an unfriendly disposition towards the United States.' In 1825 Monroe retired to his seat at Oak Hill, Loudon county, Virginia, where he acted as justice of the peace, a regent of the university of Virginia, and member of the state convention; but a profuse generosity and hospitality caused him to be overwhelmed with debt, and he found refuge with his relations in New York, where he died in 1831—like his predecessors, Adams and Jefferson, on the 4th of July.

See *Monroe's Writings*, ed. Hamilton (1898, &c.); *Lives* by J. Q. Adams (1850) and D. C. Gilman (1893); and books on the 'Monroe Doctrine'—really formulated by J. Q. Adams (q.v.)—by Tucker (1885), Reddaway (1898), Pollock (1903), Edgington (1905), Kraus (1913), Hart (1916), Alvarez (1924).

Monrovia. See **LIBERIA**.

Mons (Flem. *Bergen*), the capital of the Belgian province of Hainault, on the Trouille, 38 miles SSW. of Brussels. Its fortifications, renewed and strengthened since 1818, were demolished in 1862; but the country around can be laid under water. The Canal de Condé connects Mons with the Scheldt. The church of St Waudru (1450-1589) is a masterpiece of Gothic; and there are a town-hall (1458), a belfry (1662) 275 feet high, a good library, &c. The manufactures include woollen and cotton goods, cutlery, and sugar; whilst the vicinity forms an extensive coalfield. Pop. 28,000. Mons, occupying the site of one of Cæsar's camps, was made the capital of Hainault by Charlemagne in 804. France, Spain, and Austria often contended for its possession. The retreat of the British from Mons in August and September 1914 has given it a new fame. See Boussu's *Histoire de Mons* (2 vols. 1868).

Monsignore, a title of honour given to prelates of the Roman Catholic Church. Formerly in France the corresponding title of *Monseigneur* was allowed to all high dignitaries of the church, to the princes of the blood-royal, to the higher nobles, and to the presidents of the superior law-courts. But from the time of Louis XIV. *Monseigneur* without further addition was appropriated as the title of the Dauphin.

Monsoon is derived from the Arabic *Mausim*, 'a set time,' 'season,' and was for long applied to

those winds prevailing in the Indian Ocean which blow from the south-west from April to October, and from the opposite direction, or north-east, from October to April. The monsoons, in common with all winds whether regular or irregular, depend primarily on an unequal distribution of temperature and moisture over that portion of the earth's surface where they occur, which in its turn gives rise to an unequal distribution of atmospheric pressure. From this unequal distribution of the mass of the earth's atmosphere winds take their rise—winds being simply the flow of the air from a region of higher towards a region of lower pressure, or from where there is a surplus to where there is a deficiency of air. The term monsoon has in recent years come to be used with a wider significance than formerly; it is now generally applied to the winds connected with all continents which are of regular occurrence with the periodical return of the seasons. The winds of Australia are thus strictly monsoonal; over the greater part of North America the prevailing winds have a well-marked monsoonal character; similarly, monsoons occur on the coasts of Brazil, Peru, North Africa, and all other regions that happen to lie between regions whose temperature, and necessarily their pressures also, differ markedly from each other at different times of the year. See **WIND**.

Monstrance (Lat. *monstrare*, 'to show'), called also **OSTENSORY**, the sacred utensil employed in the Catholic Church for the purpose of presenting the consecrated host for the adoration of

Monstrance.

the people, as well while it is carried in procession as when it is exposed upon the altar on occasions of special solemnity and prayer. It consists of two parts, the foot or stand upon which it rests, and the repository or case in which the host is exhibited. The latter contains a small semi-circular holder called the *lunula*, or crescent, in which the host is fixed; and it appears anciently to have been of a cylindrical or tower-shaped form, in the central portion of which, consisting of a glass or crystal cylinder, the host was placed. At present it is more commonly in the form of a star or sun with rays, the central portion of

which is of glass or crystal, and serves to permit the host to be seen. This portion, or at least the crescent, is of gold or of silver gilt; the rest is generally of the precious metals, or at least gilt or silvered, although the lower portion is occasionally of bronze artistically wrought.

Monstrosity is the term applied in human and comparative anatomy to an aberrant formation of the body consequent upon early disturbances in the developmental processes in the embryo. Teratology (q.v.), the special and very interesting branch of biology which deals with the causes of such occurrences and with the classification of the 'monsters' so produced, has been advanced by the researches of Geoffroy Saint-Hilaire, Förster, and others to the position of a special science, and one that throws a valuable side-light on that of normal

embryology. The malformations to be dealt with may affect the whole organism or portions only of its structure. Monsters are, however, usually classified under three headings: (1) Those with exaggerated or supernumerary parts (*monstra per excessum*); (2) those lacking parts (*monstra per defectum*); and (3) those with abnormally arranged parts (*monstra per fabricam alienam*). Those of the first class, where supernumerary limbs or a double head or trunk exist, are generally recognised as due to the more or less complete fusion of two embryos, originally separate, during the process of development. Cases of this kind show that almost every possible degree of fusion of separate embryos may occur, resulting in a correspondingly great variety in the shapes of the monsters produced. Two otherwise complete bodies may be attached by an external bond, as in the case of the Siamese twins and the 'two-headed nightingale,' or the one may be wholly or partially enclosed by the tissues of the other. A case of such complete inclusion is found in the Hunterian Museum. Much more frequently, however, only imperfect relics of the one remain attached to, or fused with, the fully-developed structures of the other. Thus arise two-headed monsters, those with double trunks or double sets of limbs, and those in which a shapeless mass representing the blighted embryo remains attached to the fully-formed body of the other. In this same class of monsters by exaggeration must be placed also cases of general or local gigantic development, due not to fusion of separate embryos but to general or local precocity of growth in the tissues of a single organism. Not less interesting are monsters of the second class, where entire parts of the body may be suppressed during development. Here again it is shown that the non-development may occur in any region and to any extent: consequently numerous and widely separated varieties of monster are found in this class. For instance, a headless or brainless monster is of necessity incapable of living; whereas one with suppression of a limb is viable, and might more properly be described as a case of congenital deformity. In the third class are the cases of transposition of viscera, malposition of limbs, congenital dislocations of joints, &c. and cases more resembling lower types of animals, dogs, or apes, &c. See DEFORMITIES, CLUB-FOOT, and, for monstrosity in plants, TERATOLOGY.

Montagnana, a town of Northern Italy, 32 miles SW. of Padua; pop. 12,000.

Montagnards, or simply MONTAGNE, 'the Mountain,' the name given to the extreme democratic politicians in the first French Revolution, because they seated themselves on the highest benches of the hall in which the National Convention met. The body included both Jacobins and Cordeliers; its principal members were Danton, Marat, Robespierre, St Just, and Collot d'Herbois, the men of 'the Reign of Terror.' The antagonistic party were 'the Plain,' the Girondists (q.v.), who sat on the lowest benches, on the floor of the house. After the overthrow of the Girondists this part of the house was styled 'the Marsh or Swamp,' and included all the members whose votes were under the control of 'the Mountain.' In 1848 the extreme party in the National Assembly, composed of revolutionary democrats and communists, sometimes flattered itself by assuming the title of 'the Mountain.'

Montagu. The illustrious family of Montagu springs from Drogo de Montacute, who came from Normandy with the Conqueror. Sixth in descent from him was Simon de Montacute, grandfather of the William de Montacute created Earl of Salisbury in 1337, many of whose successors have

been great historical personages. The subsequent family of Montagu descended from Simon (younger brother of the third Earl of Salisbury), who was the ancestor of Sir Edward Montagu, Speaker of the House of Commons and afterwards Lord Chief-justice, who died in 1557. His son, Sir Edward Montagu of Boughton, had six sons; Edward, the eldest, was made Baron Montagu of Boughton; and his grandson Ralph, third baron, was (1689) created Earl of Montagu, and in 1705 Duke of Montagu. In his son John the male line of the first Baron Montagu became extinct. The third son of Edward of Boughton was Sir Henry Montagu, the famous lawyer and orator, who was Lord Chief-justice, and created Lord Montagu of Kimbolton, and afterwards (*temp.* Charles I.) Earl of Manchester (q.v.). His son (second earl) was a general in the parliamentary army, who gained distinction by his victory over Prince Rupert at Marston Moor, but subsequently gave in his adhesion to Charles II. on his restoration. The fourth Earl of Manchester was an enthusiastic follower of William III., fighting with him at the battle of the Boyne, and taking part in the siege of Limerick; he was eventually created Duke of Manchester in 1719 by George I. The sixth son of Edward of Boughton was Sir Sydney Montagu, whose son, Edward, was a considerable mathematician, and serving first in the army, then in the navy, became the first sole commander of the English navy, and was created by Charles II. Lord Montagu of St Neots, Viscount Hinchinbroke, and Earl of Sandwich.

Montagu, CHARLES. See HALIFAX (LORD).

Montagu, ELIZABETH (1720-1800), daughter of a Yorkshire squire named Robinson. After the death of her husband (a grandson of the Earl of Sandwich) became 'the Queen of the Blue-Stockings,' and wrote on Shakespeare against Voltaire. See books by Miss Climençon (1906) and R. Huchon (1907); also articles BLUE-STOCKINGS, SALON, and books there named.

Montagu, LADY MARY WORTLEY, born about 1690 at Thoresby, Nottinghamshire, was the eldest daughter of Evelyn Pierrepont, Earl (afterwards Duke) of Kingston, who, a widower, introduced his daughter to society at a very early age. In 1712 she married, without the consent of her father, Edward Wortley Montagu, grandson of the first Earl of Sandwich. For more than three years after her marriage she lived at Wharnccliffe Lodge, near Sheffield, where her son was born, her husband during this time being kept principally in London by his parliamentary duties. On the accession of George I. Mr Montagu obtained a seat at the Treasury Board, and from this time Lady Mary lived in London, where she gained a brilliant reputation by her wit and beauty, and was on terms of intimate friendship with Addison and Pope, and other literary men of the day. In 1716 Mr Montagu was appointed ambassador to the Porte, and in August of that year he set out for Constantinople, accompanied by his wife. They remained abroad till 1718, and during this time Lady Mary wrote the well-known *Letters* to her sister, the Countess of Mar, Pope, and other friends. The *Letters* give a true description of Eastern life and manners, and are written in a clear, lively style, sparkling with wit and humour. While in Turkey she witnessed Inoculation (q.v.), and introduced it into England on her return, having so much faith in its safety that she tried it first on her own son. The next twenty years of her life she passed in England, and fixed her abode at Twickenham, where she renewed her intimacy with Pope, and then quarrelled with him, but not, as was said, because of the publication by Lady Mary of six satirical sketches entitled *Town Eclogues*. In

1739, for reasons which are not well known, she left England and her husband, from whom, however, she parted on very good terms, though they never met again. She lived in Italy, first on the shores of the Lake of Iseo, and afterwards at Venice till 1761, when, at the request of her daughter, the Countess of Bute, she returned to England. She died 21st August 1762. A collected edition of her works, with Life, was published by her great-grandson, Lord Wharncliffe (3 vols. 1837; 3d ed. 1887). See a book by G. Paston (1907), and numerous editions of selected Letters.

Montague, CHARLES EDWARD, born in 1867, in 1890-1925 was on the staff of the *Manchester Guardian*, well known as a brilliant journalist. In 1910 he published *A Hind let Loose*, a novel dealing with journalistic life; and *Dramatic Values* in 1911, but it was only in 1922 when his *Disenchantment* appeared that he became the great modern exponent of the language of indignation. This book of rare literary grace and style is a burning indictment of war with its abuses and super-abuses, and is worthily followed by *Fiery Particles* (1923).

Montaigne, MICHEL EYQUEM DE, was the third son of Pierre Eyquem, Seigneur de Montaigne. He was born 28th February 1533 on the family estate in Périgord. His father had ideas of his own on education, and his third son was to have the full benefit of them. The first novel step was the putting of Michel out to nurse in a village on the estate, that he might be early inured to simple habits of living, and learn to sympathise with the lot of the poor. Whether or not the result of this early association, it is the fact that in his after life Montaigne always spoke of his poorer neighbours with a respect and kindness of tone remarkable in the age and class to which he belonged. It was the received opinion at the period of Montaigne's childhood that no boy could grow into a creditable citizen without a severity of discipline which would now be called brutal terrorism. It was the distinctive feature of Pierre de Montaigne's system, however, that boyhood should be made as happy as parents and teachers could make it, and in the upbringing of his famous son he was even whimsically humane. Every morning he had the boy awaked by the sound of some musical instrument, because he had heard 'that it disturbs the tender brain of children to awake them suddenly.' As he wished to make his son a scholar, and Latin was, therefore, an indispensable acquisition, he had the idea of converting a task into a natural pleasure. Till the age of six the boy was taught to speak no language but Latin, his tutor (a German), his parents, and even the domestics addressing him in that language. The result was that in the conversational command of Latin Montaigne had from boyhood the advantage of the best scholars of the day. His father was less successful in a novel method he also adopted in having him taught Greek.

When Montaigne reached the age of six his father 'allowed himself to be won over to common opinion,' and sent him to a school in the neighbouring city of Bordeaux—the Collège de Guienne, then, he himself tells us, the best in all France. His father, who as a former mayor had considerable influence in the city, 'made several stipulations against the rules of colleges, though, all the same, it still remained a college.' At this school Montaigne remained for seven years, boarding in the rooms of his successive teachers, among whom were two scholars of European celebrity, George Buchanan and Marc-Antoine Muret. The course of study in the college was almost exclusively the reading of Latin authors, and in after life Montaigne affirmed

that, so far as he could judge, all these years were lost.

As a third son he had to choose between law and the church—only the eldest having the privilege of wearing the sword. All his life Montaigne had an insuperable difficulty in making up his mind, and on this occasion his father saved him the trouble by setting him to the study of law. In what school he pursued his legal studies has not been discovered, all that we know of them being summed up in his own sentence—'While a child I was plunged up to the ears in law, and it succeeded.' From the age of thirteen to twenty-four Montaigne is almost lost sight of. Casual references in his *Essais* prove that during this period he was frequently in Paris, that he knew something of court life, and that he took his full share of its pleasures. His legal studies received their reward in his appointment as member of the Court of Aids in the district of Périgord; and in 1557, by the consolidation of this court with the Parlement of Bordeaux, Montaigne became a city counsellor. The office was an honourable one; but it was little to Montaigne's taste, who, in truth, is never weary of telling us that every form of restraint was against all his natural inclinations. It was during his tenure of this office that he formed his famous friendship with Etienne de la Boétie (1530-1563), a relation which he always regarded as the happiest and most memorable of his life. To Montaigne La Boétie seemed in gifts of soul and intellect the equal of the greatest characters of antiquity. From the writings La Boétie left behind him (poems and a political pamphlet, *Le Contr' Un*, advocating extreme republicanism), it seems probable that Montaigne exaggerated his powers. This devoted friendship, so soon cut short by La Boétie's death, never failed to raise Montaigne above himself, and adds the one romantic touch to his epicurean temper.

Montaigne held the office of counsellor for about thirteen years; but of this period of his life, also, no definite history has been recovered. From incidental remarks of his own we gather that he was familiar with the court of Francis II., that he saw and greatly admired Mary, Queen of Scots, and that at some time or other he was 'gentleman of the bedchamber in ordinary,' an office that did not necessitate residence at court. From Charles IX. he received the order of St Michel, instituted by Louis XI., and once a coveted honour, but in Montaigne's day somewhat faded in its lustre. On 27th September 1565 he married Françoise de la Chassaigne, the daughter of one of his fellow-counsellors in Bordeaux, though in taking the step he assures us that he merely yielded to convention, as of his own inclination 'he would not have married Wisdom herself.' As the times went, Montaigne was a faithful and considerate husband; but he makes no secret that his wife held but a subordinate place in his thoughts. He lost 'two or three' children (the expression is his own) in their infancy, and was survived by one daughter, of whom, as he speaks little in his writings, it may be concluded that she was bound to him by no peculiar tie of affection. At the request of his father (who died in 1568) he translated (and published in 1569) the *Natural History* of Raymond de Sebond, a Spaniard, who in the preceding century had professed theology, philosophy, and medicine at Toulouse. This translation is noteworthy as being Montaigne's first effort in literature, and as having afterwards supplied the text for one of his most famous essays, the *Apologie de Raymond Sebond*, in which he exhibits in all its bearings the full scope of his sceptical philosophy. Two years later he published certain literary remains of his friend La Boétie (1571).

In 1571, his two elder brothers being dead, Montaigne retired to the Château de Montaigne, and here till his death in 1592 he lived the life of a country gentleman, varied only by a few visits to Paris, and by eighteen months' travel in Germany, Switzerland, and Italy. It was during this period that he achieved his immortality. Finding on his retirement to his château that some mental occupation was imperatively necessary to save him from morbid fancies, he began those *Essais* which were to give him a place among the first names in literary history. If we know few incidents regarding this period of his life, we have at least the minutest record of his entire surroundings, of his daily manner of life, of his tastes, his habits, his speculations and imaginings. In 1580 two volumes of *Essais* appeared at Bordeaux, in 1588 a third volume was added, and in 1595 a new and augmented edition was published. In June 1580, partly on account of his health, and partly from his strong natural curiosity to know strange countries, he set out on the prolonged course of travel above mentioned. His record of this journey, dictated to his secretary, and partly written in his own hand in French and Italian, was discovered in his château, and first published in 1774. While at the baths of Lucca, the announcement came to him that he had been unanimously elected mayor of Bordeaux. He at first refused the appointment, but at the instance of his friends and on the command of Henry III. he withdrew his declination. The office, which had been held by his father before him, was of high military as well as civil rank, his immediate predecessor having been the Duc de Biron, one of the marshals of France. In spite of his natural indolence and indecision he must have performed his duties to the satisfaction of the citizens, as they did him the unusual honour of re-election. Of his last years the only circumstance deserving special record is his relation with Mademoiselle de Gournay, who won his heart by her enthusiastic admiration of his essays when she was only nineteen. After a meeting in Paris a romantic friendship sprang up between them, which lasted till Montaigne's death; and it is to Mademoiselle de Gournay, his *fille d'alliance*, as he called her, that we owe the valuable edition of the *Essais* published in 1595 (final ed. 1635) from Montaigne's annotated copies. Montaigne in his later years suffered much from stone and gravel, but at the last he died of quinsy after a few days' illness in his sixtieth year, 13th September 1592. Notwithstanding the free expression of scepticism in his writings, he devoutly received the last offices of the church.

The conclusive attestation to Montaigne's varied power is the fact that three centuries after his death the circle of his readers widens every year, and that he has now almost as large a following of antiquaries as Shakespeare himself. Of his admirers in every generation it has also to be remarked that they are of all types of mind and creed, and that among them are found men like Pascal, who, while separated from him as by an abyss on all the fundamental problems of life, have acknowledged their debt to his fearless and all-questioning criticism. To have thus commanded the attention of the acutest intellects of every age since his own by haphazard remarks, devoid of all method, and seemingly inspired by the mere caprice of the moment, could be the privilege only of a mind of the highest originality, of the very broadest sympathies, and of a nature capable of embracing and realising the largest experience of life. In achieving this distinction, what are reckoned among his chief defects have doubtless stood him in as good stead as his merits. His inconclusive philosophy, his easy opinions on many points of morals, his imperfectly developed sense of duty, the total

absence of any heroic strain in his nature, were but the necessary conditions of that general attitude towards men and things which make him the unique figure he is in the history of European literature.

There are translations by Florio (q.v.; new ed. by Saintsbury, 1893) and by C. Cotton (q.v.), revised by Hazlitt (1865; new ed. 1923); and of the *Journals* by Waters (1903-4). See books on him by St John, Lucas Collins, Miss Lowndes (1898), Dowden (1906), Merezkowski (1907), Miss Sichel (1911); essays by Emerson, Mark Pattison, Dean Church; Miss Norton's *Studies in Montaigne* (1905); Grün, *Vie Publique de Montaigne* (1855); and monographs by Bonnefon (1893, 1898), Paul Stapfer (1895, 1896), Strowski (1906). There are editions of the *Essays* by Courbet and Royer (5 vols. 1873-91), by Motheau and Jouaust (7 vols. 1886-88), Strowski (1903 et seq.). An important edition of the *Œuvres Complètes*, ed. Armaingaud, was begun in 1923.

Montalcino, a cathedral city of Central Italy, on a hill, 22 miles SSE. of Siena; pop. 9500.

Montalembert, CHARLES FORBES RENÉ DE, born in London, 15th May 1810, was the eldest son of a noble French *émigré* and his English wife. His grandfather, Mr Forbes, a retired Indian merchant, living at Stanmore, near Harrow, had charge of him from an early age, as his father went back to France with the restored Bourbons and was rewarded for his zeal in their service by being named a peer of France and minister-plenipotentiary to Stuttgart. When Charles was eight years old he was sent to school at Fulham, but was there for a very short time, as the following year his grandfather died, and he went to his parents in Paris. He was fourteen when the head of the Collège St Barbe induced them to place him under a regular course of study. At sixteen he entered the college, and left it at nineteen to join his father, then ambassador at Stockholm. He returned to Paris in 1829, and during a period of uncertainty as to his future career occupied himself by writing an article upon Sweden, which appeared in the *Revue Française*. In 1830 he went to Ireland, and, returning full of enthusiasm for religious freedom, at once eagerly joined himself to the Abbé Lamennais and Lacordaire in their enterprise of the *Avenir*, the well-known High Church Liberal newspaper. In 1831 Montalembert and Lacordaire opened a free school in Paris, which was immediately closed by the police, and a prosecution commenced against the schoolmasters. The death of Montalembert's father at this time having raised him to the peerage, he appealed to be tried by his peers, and pleaded with great eloquence the cause of the church and the common interests of religious liberty. Though he was reprimanded and fined 100 francs, this defeat had the effect of a victory. In the same year the *Avenir* was temporarily suspended, and finally given up, being condemned by the pope. After this Montalembert for a time withdrew from France and lived in Germany, where he was inspired with the idea of writing the *History of St Elizabeth*, which was published in 1836. In 1835 he returned to Paris, and made his first speech as a member of the Chamber in defence of the liberty of the press.

He married a daughter of Count Félix de Mérode in 1836. The winter of 1842 he spent in Madeira for his wife's health, and while there wrote a pamphlet entitled *Devoir des Catholiques dans la Question d'Enseignement*, in which he protested against the monopoly of education by the French University, and pleaded for free education, or, in other words, religious education guaranteed by common liberty. For this cause he fought unweariedly in parliament till it was won. His protests against tyranny, however displayed, came to a climax in a great speech in January 1848 upon Switzerland. The Revolution took place a month later; and in April Montalembert was elected a

member of the National Assembly. When the *coup d'état* of December occurred he supported Louis Napoleon till the confiscation of the Orleans property. Then he at once resigned his post as a member of the Consultative Commission, and became thenceforth a determined opponent of the imperial régime. He was admitted to the Academy on 5th February 1852, and from that time occupied himself with literary work. After a visit to England in 1855 he wrote *L'Avenir politique de l'Angleterre*. Three years later he published an article in the *Correspondant*, called 'Un Débat sur l'Inde au Parlement Anglais,' in which he made such exasperating allusions to the imperial government that he was prosecuted and sentenced to six months' imprisonment and a fine of 3000 francs. The sentence was, however, remitted by the emperor. His great work (unfinished, somewhat panegyric) was *Les Moines d'Occident* (7 vols. 1860-77; trans. 1861-79). He also wrote *Une Nation en Deuil: la Pologne* (1861), *L'Eglise libre dans l'Etat libre* (1863), *Le Pape et la Pologne* (1864), &c. During the last ten years of his life he suffered from the malady of which he died in Paris on 13th March 1870, sixteen days after writing his celebrated letter on papal infallibility.

Montalembert was one of the best French orators of his day, a great statesman and author, an accomplished man of the world, and a devoted, noble-minded son of the church. He loved freedom more than all the world, and the Catholic religion more than freedom; and thus, while he fought all his life for freedom, in questions of faith he submitted his will and intelligence to the judgment of Rome. See *Lives* by Mrs Oliphant (1872), *De Meaux* (1897), and *Lecanuet* (3 vols. 1895-1902).

Montana, one of the north-western states of the American Union, extends from 104° to 116° W. long., and from 44° 15' to 49° N. lat., and is bounded N. by the Canadian provinces of British Columbia, Alberta, and Saskatchewan, E. by North and South Dakota, S. by Wyoming and Idaho, and W. by Idaho. In area—146,080 sq. m., or nearly five times the size of Scotland—it ranks third among all the states and territories, but in population only thirty-ninth; the density of the population is but 3·8 persons per square mile.

The Rocky Mountains, with their subsidiary ranges, occupy fully one-fifth of the surface, in the south and west; the rest of the state is made up of valleys or high, rolling prairies, treeless, but yielding nutritious grasses. The head-waters of two of the largest rivers in North America—the Columbia and Missouri—have their sources in Montana. The mean elevation of the state is about 3000 feet; the average height of the Rocky Mountains—whose sides are covered with dense forests of pine, fir, and cedar—is about 6000 feet, while the highest peaks rise to 10,000 or 12,000 feet. The Yellowstone National Park (q.v.) forms part of the southern boundary of the state. In the south-east the Bad Lands extend into the state from Wyoming (q.v.). The climate of Montana is more moderate than that of the Dakotas and Minnesota, since the warm westerly winds prevail more than the north winds in winter here; there are but few excessively cold days, and, as there is little moisture in the air, the winters are less chilly and more exhilarating than in the east. The atmosphere is remarkable for its clearness, and cyclones are unknown.

The soil of Montana contains all that is needed for sustaining vegetation, but it is almost valueless without irrigation; with that, however, the yield of grain, temperate fruits, and vegetables is enormous. The federal government is constructing storage reservoirs all along the Rocky Mountain range, to store water for this purpose from the

melting snows in spring-time. It is calculated that 20,000,000 acres of land can thus be brought under cultivation. Placer mining being practically exhausted, a large part of the population has turned its attention to stock-raising, for which Montana is better suited than for agriculture. The prairies produce several varieties of bunch grass, which cures on the stalk in August, and retains all its nourishing qualities throughout the year; stock on the range receive no other feed, summer or winter, and very little shelter is required.

But the great industry of Montana is the mining and reduction of her gold, silver, copper, zinc, and other ores. Her minerals first attracted immigration, and have hitherto been her principal wealth. The first systematic working of placer mines for gold commenced in 1862; in 1863 the first gold-quartz mill was built. Montana is one of the three most important states in the production of copper. Other mineral products are coal, lead, manganese, sapphires, petroleum, lime, tungsten, and clay.

History.—The portion of Montana east of the Rocky Mountains was part of the Louisiana Purchase; that lying to the west formerly composed a part of the territorial district of Oregon. It was first visited by the French in 1742-43, and by Lewis and Clarke in 1804-6; these were followed by fur-traders and trappers, and by Jesuit missionaries, who established schools for Indian boys and girls. Gold was discovered in 1861, and mining began in earnest the following year. In 1864 the territory was organised, and on 8th November 1889 Montana became a state of the Union. Education, for a frontier state, is well organised, there being, besides the district schools, the State University at Missoula, the Agricultural College at Bozeman, and the State School of Mines at Butte. The chief cities are Butte (41,611), Great Falls (24,121), Billings, Missoula, and Helena (12,037), the capital. Pop. (1880) 39,159; (1900) 243,329, including 10,746 Indians; (1910) 376,053; (1920) 548,889. Troubles with the Indians have been frequent: in 1876 General Custer (q.v.) and his command were all killed on the Little Big Horn by the Sioux.

Montanism, a heresy which grew up within the Christian church in the second half of the 2d century; its founder was Montanus, a religious enthusiast who appeared at Ardaban in Phrygia in the year 156, with a mission to purify and re-organise the church. Christianity had now become adopted by men in all classes, and already it had to a great extent ceased to be what it was originally—a society of enthusiastic devotees shut off from the world. At the same time the church adapted to her use everything of value in the social and political arrangements of the world around her, and thus fitted herself for the rôle of a great world-religion. Side by side with this growing secularism there sprang up a natural reaction in favour of the old discipline and severity, and nowhere was this so strong as in Phrygia, where it was linked with a belief in a new and final outpouring of the Spirit. Here there quickly formed themselves societies of *spiritual* Christians who gladly hailed the appearance of the 'Paraclete,' and were gradually compelled to withdraw from the church, branded as Montanists and Kataphrygians. Montanus selected the small Phrygian towns of Pepusa and Tymion as the Jerusalem of the church, and for twenty years his movement was limited to Phrygia and the surrounding district. He himself enjoyed a continuance of the prophetic gift, as well as the two women Prisca and Maximilla; his most zealous missionaries were Alcibiades and Theodotus. The persecution that began after the year 177 spread the movement wider by deepening the earnestness of conviction in those that held fast their faith. In Phrygia they were sternly repressed by the bishops,

and formally excommunicated; but elsewhere than in Asia Minor they did not at once leave the church, but formed small conventicles within it. In Gaul and Rome it was long held that communion should be maintained with them. But gradually separation became necessary, as the Montanists became stronger in their demand for a return to primitive discipline, for more fasting, the prohibition of second marriages, and a severer life generally. Denunciation and exclusion produced their natural effect in making them still more narrow, severe in their judgments, and arrogant in their asceticism. At Carthage a numerous body of Montanists had grown up, and from 202 to 207 they strove hard, but in vain, to remain within the church, but at length quitted it because it refused to recognise the new outpouring of the Spirit. It was now that the great Tertullian joined their ranks, having become profoundly convinced of the necessity for a return to primitive Christianity in order to heal the secularism of the church. Montanism survived in the East till the 4th century; in the West it was ever less aggressive, and did not grow up until the Catholic Church had firmly established its organisation. Therefore it never became more than a mere sect; and from a genuine desire for reform and simplicity it degenerated into an artificial strictness and mere legalism. Yet down to 400 A.D. there were still Tertullianists at Carthage.

See Ritschl's *Entstehung der Altkatholischen Kirche* (2d ed. 1857); De Soyres, *Montanism and the Primitive Church* (1878); Bonwetsch, *Die Geschichte des Montanismus* (1881); Weizsäcker in *Theol. Lit.-Zeitung* (1882); and Harnack, *Das Mönchthum, seine Ideale und seine Geschichte* (4th ed. 1895; Eng. trans. 1901).

Montargis, a town in the French department of Loiret, 47 miles E. by N. of Orleans, with a fine church (12th century—1868) and ruins of a vast castle, once 'le berceau des Enfants de France.' Here in 1371 is said to have occurred the famous judicial combat between 'the dog of Montargis' and Macaire its master's murderer. The dog not only showed the spot in the forest of Bondy where its dead master was buried, but singled out the murderer, and, when Charles VI. granted the ordeal of battle to test his guilt, the dog flew at his throat and so proved its charge upon his body. Pop. 13,000.

Montauban, the capital of the French department of Tarn-et-Garonne, on the river Tarn, 31 miles N. of Toulouse. A well-built, handsome place, it has a modernised brick bridge (1335), 224 yards long; a fine cathedral (1739) in the Italian style; and a monument (1871) to Ingres, the painter, a native. Besides considerable woollen manufactures, it carries on a great trade in wine, grain, leather, &c. Montauban was founded in 1144 by Count Alphonse of Toulouse, became the seat of a bishop in 1317, embraced the Reformation in 1560, and acquired historical celebrity as the great stronghold of the Huguenots, being vainly besieged for three months by De Luynes for Louis XIII. in 1621. It suffered much in the Dragonnades; but nearly half the inhabitants still are Protestants, and maintain a theological college. Pop. 26,000.

Montbéliard (Ger. *Mömpelgard*), a town in the French department of Doubs, 48 miles NE. of Besançon. It lies in a valley between the Vosges and Jura Mountains, is surmounted by an old château (now a prison), and carries on manufactures of watch-springs, watchmaking tools, and cotton. A possession of the House of Württemberg from 1397, it was a Protestant centre from 1525, was formally ceded to France in 1801, and suffered much in the Franco-German war. Cuvier was a

native; and there is a statue of him, as also of Colonel Denfert, the heroic defender of Belfort. Pop. 10,000, mostly Lutherans.

Mont Blanc, the highest mountain in Europe (if we regard the Caucasus, q.v., as Asiatic), 15,782 feet above sea-level, is situated in France, close to the Italian frontier, 40 miles S. of the Lake of Geneva. The waters which spring from its western slopes are drained off to the Rhone, those which originate on the east side to the Po. It rises into several sharp peaks (*aiguilles*) and forms great glaciers—the Glacier du Géant, Mer de Glace, &c. In 1760 Saussure offered a prize for the discovery of a practicable route to the summit of Mont Blanc, which was gained, in June 1786, by Dr Paccard of Chamonix and Balmat, a guide. Saussure himself ascended the mountain the following year; and since Albert Smith published a description of his ascent in 1851 the mountain has been climbed by great numbers. A funicular railway is being built. There is an observatory (1890) at a height of 14,271 feet; another on the summit became unsafe, and was demolished in 1909. See ALPS; and Whymper's *Guide to Chamouni and the Range of Mont Blanc*.

Montbrison, a French town in the department of Loire, 35 miles SW. of Lyons, with mineral wells and some ribbon manufacture; pop. 8000.

Montcalm. Louis Joseph, Marquis de Montcalm Gezan de Saint Véran, was born in the château of Candiac, near Nîmes, 29th February 1712. At fifteen he entered the army. In 1746 he was severely wounded and made prisoner at the battle of Piaccenza. In 1756 he assumed command of the French troops in Canada, and soon after his arrival captured the British post of Oswego. The succeeding summer he crossed Lake George with about 8000 French and Indians, and captured Fort William Henry. After the French had taken possession of the fort, the defenceless prisoners, comprising men, women, and children, were massacred by the Indians. Montcalm has been blamed even by his apologists for not foreseeing the danger, and taking effectual measures to avert it. In 1758 General Abercromby advanced on Ticonderoga with 15,000 regulars and provincial troops. The place was defended by Montcalm with a much smaller force of regular troops. The British troops displayed heroic daring and courage, but after repeated attempts to force the defences, which were in themselves almost impregnable, and were defended with great gallantry, they withdrew with a loss of about two thousand men. This French success was, however, much more than counterbalanced by the loss of Louisburg and Fort Duquesne about the same time. Montcalm then removed to Quebec, and prepared to defend it against a British attack. Of the 16,000 troops under his command the majority were militia and Indians. In 1759 General Wolfe ascended the St Lawrence with about 8000 troops, and a naval force under Admiral Saunders. After repeated attempts to scale the heights of Montmorency, and a severe repulse about the end of July, he surprised a French outpost before dawn on 13th September, scaled the heights with about 5000 men, gained the plateau of Quebec, and formed in line of battle on the Plains of Abraham. In the battle that ensued the French ultimately broke in disorder and retreated on the city. Montcalm tried in vain to rally his force, and, having been borne back by the pressure of the retreat, he was mortally wounded at the St Louis gate, and died the following morning. See the article WOLFE; Parkman's *Montcalm and Wolfe* (Boston, 1884); Falgairolle's *Montcalm devant la Postérité* (Paris, 1886); Casgrain's *Wolfe and Montcalm* (1906).

Mont Cenis, or MONTE CENISIO, an Alpine peak and pass between Savoy and Piedmont. Height of the mountain, 11,792 feet; of the pass, 6884 feet. Over the pass a road was constructed (1802-10) by Fabbioni, under Napoleon's orders, at an expense of £300,000. Thirteen miles west of the pass a railway tunnel, $7\frac{1}{2}$ miles long, was begun in 1857 on the Italian side, and in 1863 on the French, and was finished in 1870 at a cost of £3,000,000. Through this tunnel passes one of the main continental overland routes from London *via* Paris to Brindisi, for Asia, Australia, and East Africa, now of diminished importance.

Mont-de-Marsan, capital of the French department of Landes, at the confluence of the Midou and Douze, 92 miles by rail S. of Bordeaux. It has a mineral spring, and manufactures of chemicals, iron, resin, turpentine, pit-props, &c. Pop. 10,000.

Mont de Piété, called in Italy MONTE DI PIETA, a charitable institution the object of which is to lend money to the poor at a moderate rate of interest. It was closely modelled on the 'Monte,' a precursor of the modern bank, in which the creditors, or the parties who supplied the capital, formed a close corporation, with privileged claims upon certain sources of income. These conditions were designed to avoid the laws against usury. But the Monte di Pietà did not at first levy regular interest, only a small percentage to cover the expenses of administration. The earliest of these institutions was established at Orvieto in 1463; and another followed at Perugia, 1467; yet the right to levy for the expenses of management was only conceded in 1515. The system was introduced in Spain, France, Belgium, Germany, the Netherlands, and Mexico. There exists at Paris a national pawn-broking establishment, called Mont de Piété. See PAWN BROKING.

Montdidier, a town of the French department of Somme, 21 miles SE. of Amiens, has zinc and leather industries; pop. 4500.

Mont-Dore-les-Bains, a village of Auvergne, in the department of Puy de Dôme, 26 miles SSW. of Clermont-Ferrand. It lies 3412 feet above the sea-level, in a picturesque valley, through which the river Dordogne flows, and which is bordered on both sides by rugged volcanic hills, and closed towards the south by a semicircle of jagged mountains, the highest point of which, the Pic de Sancy (6183 feet), is the loftiest mountain in central France. The Mont Dore mineral springs, which were used by the Romans, contain bicarbonates of soda, iron, and arsenic.

Monteagle, LORD. See GUNPOWDER PLOT.

Montebello Casteggio, a village of Northern Italy, 14 miles S. by W. of Pavia, where the Austrians were defeated by a French army under General Lannes (afterwards Duke of Montebello), after a desperate conflict, 9th June 1800. In May 1859 the Austrians were again defeated here by the united French and Piedmontese army.

Monte Carlo, a small town in Monaco (q.v.), 1 mile NE. of the town of Monaco, notorious on account of its gaming-tables, and the numerous suicides of ruined gamblers; pop. 10,000.

Monte-Cassino, the monastery built (529) by St Benedict, founder of the great Benedictine order, stands on beetling cliffs, in a magnificent situation, 70 miles by rail NW. of Naples and 92 SE. of Rome. It has been four times destroyed—in 589 by the Longobards, in 884 by the Saracens, in 1030 by the Normans, and in 1349 by an earthquake. It was dissolved in 1866; but a few monks still remain. In 1313 the abbot was elevated to episcopal rank, and from 1504 he was official 'head of all the abbots of the Benedictine order.' The

existing church, replacing one erected in 1066, was built in 1727, and possesses an 11th-century Byzantine bronze portal, mosaics, frescoes, carvings, &c. The former monastic buildings contain valuable archives, a picture-gallery, a library, and a seminary. See Tosti, *Storia della Badia di Monte Cassino* (1843), *Archivio Cassinese* (1847), and Mackey's *Life of Bishop Forbes* (1888).

Monte Catini, a watering-place of Italy, by rail 30 miles NW. of Florence and 19 E. of Lucca. Its mineral springs range between 82° and 86° F. Near here the Florentines were defeated by the Pisans in 1315. Pop. 3400.

Monte Cristo, an uninhabited islet of granite off the Italian coast, 26 miles S. of Elba. For the novel whose hero bears this name, see DUMAS.

Montecuculi, RAIMONDO, COUNT, was born at Modena in 1608, and entered the Austrian service, distinguishing himself during the Thirty Years' War (especially at Breitenfeld and Nördlingen), in a campaign against the Turks (1664), and against the French under Turenne on the Rhine (1672-75). He was made a Prince of the Empire and Duke of Meli, and died at Linz, 16th October 1681. A second edition of his *Opere Complete* appeared in 1823; there is a *Life* by Campori (1876).

Montefiore, SIR MOSES HAIM, philanthropist, was born in Leghorn, 24th October 1784, son of a banker whose parents had emigrated from Italy to London. He retired with a fortune from stock-broking in 1824, and from 1829 was prominent in the struggle for removing Jewish disabilities. After long exclusion and repeated re-election he was admitted Sheriff of London in 1837, being knighted the same year, and made a baronet in 1846. Between 1827 and 1875 he made seven journeys in the interests of his oppressed countrymen in Poland, Russia, Rumania, and Damascus. He endowed a Jewish college at Ramsgate in 1865. In his hundredth year he was still hale and well, but died at Ramsgate 28th July 1885. See JEWS, and the *Diaries of Sir Moses and Lady Montefiore* (1890).

Montego Bay, a port of Jamaica (q.v.).

Montégut, ÉMILE (1826-95), French critic, born at Limoges, contributed to the *Revue des Deux Mondes*, and published books of travel, a study of Marshal Davout, works on Italian and English literatures, and translations of Shakespeare, Macaulay, and Emerson.

Montélimar, in the French department of Drôme, 85 miles S. of Lyons; pop. 13,000.

Montelius, OSCAR (1843-1921), born at Stockholm, wrote many works on early culture in Sweden and elsewhere, and was director of archaeology at Stockholm.

Montemayor, JORGE DE (c. 1515-61), Portuguese lyrical poet, wrote *Diana* (pastoral romance), &c., in Castilian, and influenced Sir Philip Sidney.

Montenegro (the Italian translation of the native name *Črna gora*, 'Black Mountain'), part of Yugoslavia, till 1918 an independent state in the Balkan Peninsula, between Herzegovina and Albania, about 100 miles long by 100 broad. Its area was extended in 1878 by the addition of a large district on the north, a long narrow strip right down its east side to Lake Scutari (Skadarsko Jezero), and the port and district of Antivari (Bar) on the south, in 1880 by the addition of the port and district of Dulcigno (Ulkin, Ulëinj), and in 1913, by some 2000 sq. m. in the north-east and east wrested from Turkey, making a total of about 5600 sq. m. Beyond the low coastal fringe, which has a climate like that of the south of France, comes a rugged mountain-region ranging up to 6500-8000 feet, not in a series of chains, but

in a confusing maze of peaks and gigantic crags and blocks, wild ravines and gorges, fissures and natural caves, the bare gray crystalline rock being everywhere visible. In this region the streams in some cases have underground channels, and even pass for miles beneath the mountains. The centre of the country is occupied by the branching valleys of the rivers Zeta and Morača, which flow south into Lake Scutari. East and north of them the mountains are well wooded, principally with beech and pine, and afford good pasturage to the sheep, goats, and cattle of the people. The climate in these mountainous regions is characterised by temperate heat in summer and a rigid winter. The east drains by the Lim, Drina, and Save, and by the Ibar and Morava to the Danube, and the south-east to the Drim or Drin. Comparatively little of the surface is cultivated, except in the coast region; it is too sterile. Yet agriculture is the principal occupation of the people; of industry there is virtually none. All the farms are small, the fields often patches of soil a few square yards in extent clinging to the mountain-side. The land in most cases belongs to the family, not to the individual, and woods and pastures are common to the clan. Maize, rye, oats, barley, potatoes, buckwheat, capsicums, tobacco, with fruits in the south, are the more important products. Wine for home consumption is grown on the shores of Lake Scutari; and the mulberry is cultivated for silkworms. The same lake, and some of the rivers flowing into it, yield an abundance of fish, especially of scorantza or bleak. The exports consist chiefly of cattle, goats, hides, smoked fish and mutton, cheese, sumach, fruits, and wine. A railway (1908) runs from Antivari to Lake Scutari. Good roads connect the chief towns or villages in the south; bridle-paths and footpaths only exist in the rest of the country. Cetinje is the capital. Other villages are Podgoritza or Podgorica, Dulcigno, Antivari, Nikšić, Plevlja, Djakova or Đakovica, and Peć.

The Montenegrins, a race of primitive mountaineers, whose principal business in life has for generations been to fight the Turks, are a brave, warlike, and simple people, noted for their honesty and their chastity. The men are stalwart and handsome, but the women, who until recent years did all the hard work whilst the men fought, or idled, or hunted, soon grow old and lose their good looks. The people live in small stone houses, in small villages—there is not a town, strictly so called, in all Montenegro. They belong mainly to the Serbian branch of the Slavs, with some Albanians. Pop. 200,000.

In the 14th century the country, known as the principality of Zeta, was tributary to the Serbian empire; but, when the latter was subjugated by the Turks (1389), Zeta, assisted by fugitive Serbians, successfully maintained its independence. From that time the Montenegrins waged almost incessant war against the Turks. In 1516, when the last prince of the second native dynasty abdicated his throne, the people elected their bishop to be ruler over them; and the little state was governed by ecclesiastical princes (vladikas) down to 1851, when Danilo, of the house of Petrovitch Nyegush, on succeeding his uncle Peter II. abandoned the title and ecclesiastical functions of vladika, and had the principality declared hereditary in his family, which had ruled since 1696. The prince or Gospodar was an absolute sovereign; but he was assisted by a state council and a ministry. The government both of the country and of the family was really, however, patriarchal, the will of the prince deciding all things only in so far as it did not conflict with the will of the people. In 1905 Prince Nicholas I. granted a constitution with a single chamber

elected by manhood suffrage and ballot, and in 1910, by act of the Skupschтина, he was proclaimed king. Montenegrin precipitation began the Balkan war of 1912, which increased the kingdom's area by more than half, and doubled the population. In the Great War Montenegro, siding with the other Serb kingdom, was overrun by the enemy (1916). A National Assembly which met at Podgoritza in 1918-19 declared King Nicholas deposed, and the country united with Serbia in the new state of the Serbs, Croats, and Slovenes. See YUGOSLAVIA. The vladika Peter II. (1830-51) is accounted one of the greatest poets who have written in Serbian. In their patriotic songs and ballads the Montenegrins possess a treasure of great value and of great influence upon the national temperament. The first Slavonic books to be printed were issued from presses at Cetinje and Rieka in the end of the 15th century.

Miller, *The Balkans* (1896); Wyon and France, *The Land of the Black Mountain* (1903); F. S. Stevenson, *History of Montenegro* (1912); A. Devine, *Montenegro in History, Politics, and War* (1918).

Montenotte, a small village of Northern Italy, 26 miles W. of Genoa, where Napoleon won his first victory over the Austrians on 12th April 1796.

Montepulciano, a town of Italy, a bishop's see, situated on a high hill, 43 miles by rail S.E. of Siena. It was the birthplace of Politian and Belarmino, and is famous for its red wine. Pop. 16,000.

Montereau, a town in the French department of Seine-et-Marne, at the confluence of the Seine and Yonne, 49 miles S.E. of Paris. At the bridge here, in 1419, Jean-sans-Peur, Duke of Burgundy, was assassinated in the presence of the young Dauphin, afterwards Charles VII.; and in the immediate vicinity Napoleon, on 18th February 1814, gained his last victory over the allies. Pop. 10,000.

Monterey in California, 120 miles S.E. of San Francisco, and in 1840-45 capital of the province, has a population of 5500.

Monte Rosa, an Alpine mountain mass with four principal peaks, in the Pennine ridge which separates the Swiss canton of Valais from Italy. The highest peak, the Dufourspitze, 15,217 feet high, is extremely difficult of ascent, and was first climbed by Mr Smyth in 1855.

Monterrey, capital of the Mexican state of Nuevo León, lies in a fertile plateau-valley, by rail 670 miles N. of Mexico city; pop. 88,500. Founded in 1599, it was taken by General Taylor in 1846.

Monte Sant' Angelo, a city of Southern Italy, 23 miles N.E. of Foggia. It stands 2790 feet above sea-level, on one of the Gargano hills, and is famed for its exquisite honey. Pop. 23,500.

Montespan, FRANÇOISE ATHÉNAÏS, MARQUISE DE, mistress of Louis XIV., was born in 1641, the daughter of Gabriel de Rochechouart, Duc de Mortemart, and married in 1663 the Marquis de Montespan, and became attached to the household of the queen. Her beauty and wit captivated the heart of the king, and about 1668 she became his mistress, without, however, as yet supplanting La Vallière. The marquis was flung into the Bastille, next banished to his estates, and finally in 1676 his marriage was formally annulled. Montespan reigned till 1682, and bore the king seven children, which were legitimised, but at last her influence paled before the rising star of the astute widow of Scarron, afterwards Madame de

Maintenon, whom she had engaged as governess to her children. Gradually she lost all hold over the king, and in 1687 left the court, in 1691 Paris itself. Later, like so many women of her class, she found relief in devotion, and died 27th May 1707.

See her *Mémoires* (1829; trans. 1895), and books on her by Houssaye, Clément (1868), and Noel Williams (1904).

Montesquieu, CHARLES DE SECONDAT, BARON DE LA BREDE ET DE, a celebrated French writer on politics and law, was born 18th January 1689, at the château La Brède, near Bordeaux. Jacques de Secondat, the father of the future author, was second son of the Baron de Montesquieu, president and chief-justice of the parliament of Guienne. Charles-Louis de la Brède, as Montesquieu was called, after studying the ancient classics, philosophy, and law, became councillor of the parliament of Bordeaux in 1714, and its president in 1716, succeeding his uncle, who left him all his property on condition of his assuming the name and title of Montesquieu. The young president discharged the duties of his office faithfully, but he gave himself by preference to the study of nature under the influence of Newton. In his discourses before the Academy of Sciences of Bordeaux he dealt with the causes of echoes and of the weight and transparency of bodies, and with the use of the renal glands, and sketched a project of a physical history of the earth (*Discours Académiques*, 1716-21). But defective vision compelled him to abandon experimental research. His first great literary success was the publication of his *Lettres Persanes* in 1721. These contain a satirical description of the contemporary manners, customs, and institutions of society in France, and owed much of their popularity to the ingenuity of their form and the piquancy of their style. Two Persians, Rica and Usbek, are represented as coming from Persia to Paris, and exchanging their impressions by letters to each other, as well as corresponding with their friends at home. The idea was borrowed from Dufresny, and it has been frequently imitated since. The libertinage, the political decadence, and the irreligious insincerity of the first years of the regency that followed the death of Louis XIV. are limned with masterly art. For his delineations of Persian manners and institutions he drew from the accounts of Sir John Chardin and other travellers; but his vivid, and at times wantonly sensuous, imagination created most of his situations and characters. Along with much that is frivolous and ephemeral, the *Persian Letters* contain solid reflections on the nature and relations of social institutions, and an adumbration of the author's later views on government, toleration, and the influence of climate on population, customs, and religion. In 1725 Montesquieu wrote and published anonymously at Paris a prose poem entitled *Le Temple de Gnide*, in the artificial French style of the time. Returning to Bordeaux, he read to the Academy a treatise on duty from the Stoic standpoint, and delivered an admirable discourse on the motives which ought to give encouragement in the sciences (1725). Eager for larger observation and enjoyment of the life of society, and weary of the routine of his parliamentary duty, he sold his office in 1726, and then settled in Paris. Thereafter he travelled for three years in order to observe and study the political and social institutions of other countries. He visited Vienna, where he studied the constitutions of Hungary and Poland; Venice, where he formed a close friendship with Lord Chesterfield; and Rome, where he studied Italian art, and was favourably received by the pope. He then passed by Switzerland and the Rhine to Holland, where he again met Chesterfield, who took him to Eng-

land. He remained in England from October 1729 to August 1731, mixing with its best society, frequenting the Houses of Parliament, studying the political writings of Locke, and analysing the organisation and working of the English constitution, whose essential principles he may be said to have discovered. After returning to France he divided his time between Paris and La Brède, mingling the pursuit of pleasure and an unostentatious charity with the preparation of his great works on the science of politics and law.

His *Considérations sur les Causes de la Grandeur des Romains et de leur Décadence*, the ablest, if not the most important, of his works, appeared in 1734. In it he surveys the vast political development of ancient Rome from the rude beginnings of the Eternal City till the Turks gathered around the walls of Constantinople, and his elucidation of the causes that determined the character and detail of the movement may be regarded as the first genuine application of the modern scientific spirit to history, and as an enduring contribution to its philosophy. His characterisations of the great Romans, his analysis of complex influences, his filiation of events, his estimates of political and social causation have been generally accepted and reproduced by subsequent historians. His great monumental work on the spirit of laws, *De l'Esprit des Loix*, appeared in 1748 in 2 vols. at Geneva. It was the product of all the work of his life, and of the deliberate and concentrated effort of twenty years. Although published anonymously and put on the Index, the work passed through twenty-two editions in less than two years; and it soon vindicated its claim to be the most original and popular book ever published on the science of law. Montesquieu indicated his consciousness of its originality by prefixing to it the epigraph: *Prolem sine matre creatam*. French Jurists of the 16th century, Cujas and others, had led the way to the historical treatment of Roman law, and Domat had written a chapter on 'the nature and spirit of laws,' but the universalisation of the historical and comparative method in dealing with the reason and relations of all laws is Montesquieu's own, and he applies it more lucidly, and also more widely than Vico did. By the spirit of laws he means their *raison d'être* in time, their historical causation, or the natural and social conditions by which their origination, development, and forms are determined. The discussion of the influence of climate was the most characteristic element of the work; it advances beyond the old abstract discussions of right, and, although pushed in some points too exclusively, it formed the prelude to all the more recent work of the positive and ethnological school. The analysis of the forms and principles of government carried the subject farther than had been done by any one since Aristotle; and the exposition of the constitutional government of England, with its clear distinction of the legislative and executive powers, made an advance upon Locke, and held up the free English constitution to the admiration and imitation of all Europe. The influence of Montesquieu's great work upon political and legal thought directly, and upon government and laws indirectly, was immense. It came too late to save France from the political errors that culminated in the Revolution, but it inspired and guided its best thinkers and its greatest men. In 1750 he published a clever *Défense de l'Esprit des Loix*, followed afterwards by *Lysimaque* (1748), a striking dialogue on despotism, *Arsace et Isménie*, a romance, and an essay on taste in the *Encyclopédie*. Severe study had exhausted his energy and still further weakened his eyes till he became totally blind. He died at Paris 10th February 1755.

The best edition of Montesquieu's works is that of E. Laboulaye (7 vols. Paris, 1875-79); that of Lahure (3 vols. 1856) is convenient and serviceable. See Vian's *Montesquieu* (2d ed. 1879), also Sorel (1887), Zevort (1887), Barkhausen (1907), Dedieu (1913); Churton Collins, *Voltaire, Montesquieu, and Rousseau in England* (1908); Sir C. Ilbert's *Romanes Lecture on Montesquieu* in 1904; and Faquet's *Selections from the Lettres Persanes*, with an introduction (1907).

Montessori, MARIA, born at Rome in 1870, was the first woman to take the degree of M.D. in Rome University. As a doctor in an asylum at Rome about 1895-1900 she developed a method of educating defective or feeble-minded children, which she afterwards applied to normal children. It insists on spontaneity (as in 'liberal' kindergarten schools), and looks askance on artificial restraints, rigid discipline, and conventional rules; as expounded in *The Montessori Method* by her (trans. 1913). See EDUCATION.

Mont' Estoril, a Portuguese watering-place north of the mouth of the Tagus and 15 miles W. of Lisbon.

Monteverde, CLAUDIO, composer and harmonist (1568-1643). See HARMONY, MUSIC.

Montevideo, the capital of the republic of Uruguay, is situated on the north shore of the La Plata estuary, about 125 miles E. by S. of Buenos Aires. It was built originally on a low promontory between the ocean and a horseshoe-shaped bay, 2 miles across; but its extensive suburbs now stretch far into the flat country behind, and have crept round the bay to the landmark which gives the city its name—the Cerro, a smooth, isolated cone, 505 feet high, crowned with a lighthouse and an old fort. At its base are great *saladeros*, or beef-salting establishments; and here, too, is the largest of the city's dry-docks. The city proper covers an area of about 5 square miles, the old town, on the little peninsula occupying nearly 1 square mile; and the sea-breezes make its climate both pleasant and healthy. Montevideo is an attractive town, with broad streets exceptionally well paved—the Calle 18 de Julio, which is 85 feet wide, has been declared 'incomparably the finest street in South America.' The houses are flat-roofed, mostly of two or three stories, and often crowned with small square belvederes. High above these rises the cathedral (133 feet), with two side towers and a dome covered with green and blue and yellow tiles. The next most prominent building is the large opera-house; and others are the town-hall, the custom-house, the exchange, the Cabildo (law-courts and parliament house), the school of arts and trades, the university, the museum, the English and Basque churches, two convents, the Hospital de Caridad and the British hospital, the extensive public markets, and several of the banks and hotels. The tramway system is very extensive. Water is brought by a pumping-main from the river Santa Lucia, a distance of 34 miles.

The depth of water in the bay formerly ranged from 9 to 15 feet, and vessels of heavy draught were compelled to anchor in the roadstead outside, which is exposed and often very rough. If a satisfactory port had been constructed in the years before 1864, when the Buenos Aires trade was diverted by the Paraguayan war, Montevideo might have permanently taken the place now occupied by the Argentine port; as it is, possessing the advantage of a large natural harbour, it may even yet become again a dangerous rival on the completion of the new harbour-works. Its foreign trade is that of Uruguay (q.v.). The manufactures are more numerous than important, but have increased of late years nearly as fast as the population. In 1877 there were 110,167 inhabitants, in 1890 some

215,000, in 1922 some 350,000; of these nearly half were foreigners. This foreign element—mainly drawn from Italy, France, and Spain, and engaged principally in retail trade—is a very noticeable feature of Montevideo life.—A fort was built on the Cerro, by the Spaniards, in 1717, and the first settlement of the town made in 1726; a century later (1828) it became the capital of the newly-formed republic of Banda Oriental. Its later history will be found under URUGUAY.

Montez, LOLA, adventuress, was born in 1818 at Limerick, and was christened Marie Dolores Eliza Rosanna, her father being an Ensign Gilbert, her mother of Spanish descent. Taken out to India, she there lost her father by cholera; and, her mother having remarried, Dolores (or 'Lola') was sent home in 1826 to Europe, and brought up at Montrose, in Paris, and at Bath. To escape the match, arranged by her mother, with a gouty old judge, she eloped with a Captain James, whom in July 1837 she married at Neath; but the marriage ended in a separation and in her return from India (1842). She now turned dancer, coming out at Her Majesty's Theatre; and after visits to Dresden, Berlin, Warsaw, St Petersburg, and Paris (where she formed a *liaison* with Dujarrier, a young Republican editor, who fell in a duel), she came towards the close of 1846 to Munich. There she soon won an ascendancy over the eccentric artist-king, Louis I., who created her Countess of Landsfeld, and allowed her £5000 a year. For more than a twelvemonth she was all-powerful, her power directed in favour of Liberalism and against the Jesuits; but the revolution of 1848 sent her once more adrift on the world. Again she married (this time a Lieutenant Heald), a marriage as unlucky as the first; and, after touring (1851-56) through the States and Australia, and after two more 'marriages' in California, in 1858 she delivered in New York a series of lectures written for her by C. Chauncey Burr. She died, a penitent, at Astoria, Long Island, on 17th January 1861, her last four months devoted to ministering in a Magdalen asylum near New York. See her *Autobiography* (1858); Hawks, *The Story of a Penitent* (1867); and the Life by E. B. D'Auvergne (1909, new ed. 1924).

Montezuma (more correctly and fully spelt MOTECHUHZOMA), the ablest of the Mexican emperors, son of the ruler of Tenochtitlan, ascended the throne about 1437, and soon after commenced a war with the neighbouring monarch of Chalco, which resulted in the annexation of that kingdom to Mexico. He next crushed a confederacy of the Tlascalans, and reigned safely till his death in 1471.—MONTEZUMA II., the last of the Mexican emperors, succeeded to the throne in 1502. Already distinguished as a warrior, henceforth he devoted his chief attention to the improvement of the laws, and indulged his taste for pomp and luxury at the cost of heavy taxation, leading to frequent revolts among his subjects. When Cortes landed in Mexico with his small army in 1519 Montezuma tried to buy off the dreaded enemy, but all his temporising could not prevent the conqueror's progress to his capital. Soon he himself was practically a prisoner in the Spanish camp, and when the citizens rose in revolt Cortes brought out Montezuma in order to pacify them; but an accidental wound from a stone flung from amongst the crowd of his own subjects proved a climax to all the indignities he had suffered. He repeatedly tore the bandages from his wound, and soon after died broken-hearted, June 30, 1520. Some of his children adopted the Christian religion, and his eldest son received from Charles V. the title of Count of Montezuma. One of his descendants was viceroy of Mexico from 1697 to

1701. His last descendant, Don Marsilio de Teruel, Count of Montezuma, was banished from Spain by Ferdinand VII., and afterwards from Mexico, on account of his liberal opinions, and died at New Orleans in 1836. See CORTES.

Montferrat, formerly an independent duchy of Italy, between Piedmont, Milan, and Genoa, now forming part of the kingdom of Italy. It consisted of two separate portions, both lying between the Maritime Alps and the Po, and having a united area of over 1300 sq. m. The capital was Casale. After the downfall of the Frankish empire, Montferrat was ruled by its own marquises till the beginning of the 14th century. This house sent its most illustrious sons to take part in the Crusades, especially Conrad, the defender of Tyre against Saladin, and the competitor with Guy de Lusignan for the crown of Jerusalem; and Boniface, who became ruler of Thessalia. Iolande or Irene, sister and heiress of the last male of the house, was empress of Constantinople; her second son became the founder of the family of Montferrat-Palaologus, which became extinct in 1533, and Montferrat then passed to the Gonzagas of Mantua. In 1631 the Dukes of Savoy obtained a portion of Montferrat, and in 1703 the remaining portion.

Montfort, L'AMAURI, the name of a noble French house, traditionally descended from a marriage (end of 10th century) between the heiress of Montfort and Epernon and William of Hainault, great-grandson of Baldwin, Count of Flanders, the third husband of Judith, daughter of Charles the Bald. The name was taken from the castle of Montfort between Paris and Chartres. Its most famous members were the great Simon de Montfort and his father, Simon IV., Comte de Montfort and Earl of Leicester, subsequently Comte de Toulouse, the ruthless persecutor of the Albigenses. He was born about the year 1160, went on a fruitless crusade to Palestine, but began about 1208 the more congenial crusade of extermination against the harmless heretics in the south of France. He was killed by a stone at the siege of Toulouse, 25th June 1218. See ALBIGENSES.

Montfort, SIMON DE, Earl of Leicester, the fourth son of the preceding, and of Alice de Montmorency, was born about the beginning of the 13th century. The title of Earl of Leicester came to him by his grandmother, Amicia de Beaumont, sister and co-heiress of Robert, Earl of Leicester; and in 1230 we find him in England, where he was well received by Henry III., and confirmed in his title and estates two years later. He married in 1238 the king's youngest sister Eleanor, who had been betrothed to the Earl of Pembroke, and who, in the grief of an enthusiastic girl of sixteen, at his death had taken in her haste a vow of perpetual chastity, but never proceeded to take the veil. The marriage aroused the jealousy of the barons and the denunciations of the church, whereupon Simon repaired to Rome, and there succeeded by gold in obtaining the pope's sanction. In June 1239 he was godfather at the baptism of Prince Edward, but three months later was denounced as an excommunicated man, and driven from his presence by the king. Simon crossed to France, but soon returned and was nominally reconciled. It is probable that he went on crusade to the Holy Land, but at anyrate he was again in England by 1242. We know but little of his life during the next six years, save that he lived the while at Kenilworth in intimate friendship with Robert Grosseteste, Bishop of Lincoln, and the learned Franciscan, Adam Marsh. Meantime the whole community was becoming exasperated by the misgovernment and faithlessness of the king, the extortionate exactions of the

pope, and the fresh influxes of aliens on whom the court lavished its favours.

In 1248 Simon was sent as king's deputy to Gascony, and there he put down the prevalent disaffection with a heavy hand. But his jealous master listened eagerly to the complaints brought against his vigorous rule, and actually arraigned him before a special commission of inquiry, which only acquitted him after a lengthened trial. Earl Simon resigned his post in the winter of 1252-53, and returned to England, where he again comes into prominence in 1258 in the last act of the constitutional struggle. Bad harvests, famine, and fresh exactions of Rome, added to the rapacity of foreign parasites and protégés of the king, at length exhausted the endurance of the country, and in 1258 the barons appeared in arms at the parliament at Westminster, demanding the expulsion of all foreigners, and next the appointment of a committee of twenty-four—twelve from the king and twelve from the barons—to govern the realm. Later in the year the parliament met again at Oxford, and drew up the famous Provisions of Oxford, which the king swore solemnly to observe. A council of fifteen with a baronial majority was formed to advise the king; the old parliaments were superseded by a body of twelve chosen by the barons, to meet three times a year in order to transact business along with the fifteen; and foreigners were to surrender their castles—a self-denying ordinance in accordance with which Simon himself set the example by giving up Kenilworth and Odiham. This was almost entirely a baronial policy, and did little for the sub-tenants, with whom Prince Edward now began to intrigue for influence, whilst ere long breaches followed amongst the barons themselves, so that by 1261 the king felt strong enough to announce that the pope had declared the Provisions null and void. All men now looked to Earl Simon as leader of the barons and the whole nation alike, and he at once took up arms against the king. After some varying success, both sides agreed to submit to the arbitration of Louis IX. of France, who decided in the *Mise* of Amiens for an unconditional surrender to the royal authority. London and the Cinque Ports at once repudiated the agreement, and Simon hastily collected his forces, surprised the king's army at Lewes, and captured the young prince, May 14, 1264.

After his victory he arranged the *Mise* of Lewes, by which matters were anew to be submitted to arbitration. There were to be three electors, Earl Simon, the Earl of Gloucester, and the Bishop of Hereford, who were to appoint nine councillors to nominate the ministers of state. To aid these councillors in their task a parliament was called, in which, together with the barons, bishops, and abbots, there sat four chosen knights from each shire, and for the first time two representatives from certain towns. This was the fullest representation of England that had yet been convened, and may be looked upon as in a special sense the germ of our modern parliaments. But the great earl's constitution was premature; the barons soon began to be dissatisfied with the rule of Simon the Righteous, the arrogance of his sons injured his influence, and the young Earl of Gloucester abandoned him and went over to the king. Prince Edward, escaping from confinement by a stratagem, combined with Gloucester and fell with vastly superior force upon Simon at Evesham, and completely defeated him, August 4, 1265. The earl died upon the field, and his body was barbarously mutilated by Edward's soldiers, but the people and the native clergy, with the true instinct of a democracy, cherished him as a saint. His memory was enshrined in song and ballad, and miracles

were ascribed to him long after his death.—The famous *Song of Leves* is the most complete extant contemporary statement of the views of the constitutional party, of which Simon de Montfort was the champion and martyr. It was first printed by Thomas Wright in his *Political Songs* (1839) for the Camden Society, but a more adequate edition, furnished with introduction and notes, is that by C. L. Kingsford (Oxford, Clarendon Press, 1890).

See Blaauw, *Barons' War* (1844; 2d ed. 1871); vol. ii. (1876) of Stubbs's *Constitutional History of England*; and Lives by Reinhold Pauli (1867; Eng. trans. by Una M. Goodwin, 1876), M. Creighton (1876), and especially G. W. Prothero (1877).

Montgolfier, JOSEPH MICHEL (1740–1810), and JACQUES ÉTIENNE (1745–99), two brothers, the sons of a manufacturer at Annonay, distinguished as the inventors of the first kind of Balloons (q.v.).

Montgomerie, ALEXANDER, Scottish poet, was born probably at Hessilhead Castle, near Beith, in Ayrshire, about 1545. Servitor and 'maister poet' to the king, he was awarded a pension of 500 merks a year. Traditionally he lived at Compston Castle, near Kirkeudbright. He travelled in France, Flanders, and Spain; was detained in a foreign prison; and was embittered by the loss of a long law-suit involving the loss of his pension. Implicated in Barclay of Ladyland's Catholic plot, he was denounced as a rebel in 1597. He may have died about 1611. He was small in stature, given to drinking, and unhappy in his amours. Montgomerie was the chief of a small school of court poets who wrote under Italian, French, and English influences. He had something of the tastes of the scholar, but his poems, especially the *Sonnets*, reveal a pitiful meanness and servility of character. His pasquinades are savage without being strong; *The Flying between Montgomerie and Polwart* [Sir Patrick Hume], in imitation of Dunbar, is merely coarse, vulgar, and unclean. His miscellaneous poems, mostly amatory, are laboured in style. *The Cherrie and the Slae* at once leapt into popularity. Its earlier portion is a love-allegory; its later, moral and didactic. Here at least are real freshness and descriptive power, with dexterous mastery of rhyme. See editions by Irving (1821) and Dr J. Cranston (S.T.S., 1886–87; with supplement, ed. G. Stevenson, 1910); important studies in German by Hoffmann (1894) and Brotanek (1896); and Stevenson's introduction, &c.

Montgomery, capital of Alabama, on the left bank of the Alabama River, some 400 miles above Mobile by water, contains a fine state-house and a handsome Masonic hall, and has a large number of manufactories, including foundries, flour-mills, fertiliser-factories, cotton-mills, and cotton-seed oil-works. Several railways meet here, and the river is navigable for steamboats all the year round; an active trade is carried on, and large quantities of cotton, especially, are shipped. Montgomery became capital of Alabama in 1847, and was for a time capital of the Confederate States. Pop. (1880) 16,713; (1920) 43,464.

Montgomery, a district of the Punjab, in the Multan division, and bounded by the Sutlej. The area is 4623 sq. m.; population, 714,000. Its capital, Montgomery, midway between Lahore and Multan, has 14,600 inhabitants. It was named in 1865 after the governor of the Punjab.

Montgomery, FLORENCE SOPHIA (1843–1923) writer of books for children, daughter of Sir Alexander Leslie Montgomery, Bart., of The Hall, County Donegal. Her first book, *A Very Simple Story* (1867), was warmly praised by Whyte-

Melville. Of its successors the chief was the widely popular but not entirely satisfactory *Misunderstood* (1869).

Montgomery, GABRIEL, COMTE DE, a French knight of Scottish extraction, and an officer in the Scottish Guard of the king of France, was born about 1530. At a tournament given, 30th June 1559, by Henry II. in honour of his daughter's marriage with Philip of Spain, the king insisted upon young Montgomery entering the lists with him. Montgomery reluctantly complied, and, the shaft of his broken lance entering the king's visor at the eye, Henry was borne insensible from the ground, and so continued for eleven days, when he died. Montgomery, though blameless, felt it impossible to remain about the court, and retired to the family estate in Normandy, afterwards travelling in Italy and England. On the commencement of the religious wars in 1562 he returned to support the Protestant cause, and defended Rouen with great bravery. In the third religious war he was one of the leaders of the Protestants, and gained many advantages over the royalists in Languedoc and Béarn. During the massacre of St Bartholomew he happened to be in Paris, but escaped by the swiftness of his horse, and took refuge, first in Jersey, then in England. In April 1573 he appeared off Rochelle with a small fleet, but failed in accomplishing anything, and was obliged to retire. Next year, at the head of a band of Huguenots, he landed in Normandy, and commenced war there; but being compelled at last to surrender the castle of Domfront, where he had entrenched himself, he was carried to Paris; and although the general to whom he surrendered had assured him of his life, he was beheaded, 27th May 1574.

Montgomery, JAMES, minor poet, was born at Irvine, Ayrshire, 4th November 1771, the eldest son of a Moravian pastor, and at six was sent to Fulneck in Yorkshire (see FULNEK). He there spent ten dreamy years, and then was dismissed as unfit for the ministry; but meanwhile he had read by stealth many of the poets, and had tried his own hand at verse-making. After four years of various employment—with a baker at Mirfield (from this place he ran away), a general dealer at Wath, and a bookseller in London—in 1792 he became clerk to the editor of the *Radical Sheffield Register*. In 1794 he started a weekly paper of his own, the *Sheffield Iris*; and this he continued to edit till 1825. In 1795 he was fined £20, and sentenced to three months in York Castle, for striking off some copies of a 'seditious' ballad; in 1796 it was £30 and six months for describing a Sheffield riot. Yet by 1832 he had become a moderate Conservative; and in 1835 he accepted from Peel a government pension of £150. He died, unmarried, at Sheffield, 30th April 1854. His collected Poetical Works (4 vols. 1849) include *The Common Lot* (1805), *The Wanderer of Switzerland* (1806), *The West Indies* (1809), *The World before the Flood* (1813), *Greenland* (1819), and *The Pelican Island* (1827). 'Bland and deeply religious,' these poems have outlived their vogue; but ten at least of his hymns keep their place in the hymnals. His *Memoirs* by Holland and Everett (7 vols. 1854–56) is perhaps the worst Life in the language.

Montgomery, ROBERT, poetaster, was born at Bath in 1807, the son of one Gomery, a famous clown. In 1830 he entered Lincoln College, Oxford; in 1833 took his B.A. with a fourth class; in 1835 was ordained; and, with the exception of a few years in Glasgow (1836–43), was minister of Percy Chapel, London, until his death at Brighton on 3d December 1855. Of his thirty-one works in verse and prose, two—*The Omnipresence of the Deity* (1828; 29th ed. 1855) and *Satan* (1830)—are still

remembered, but only by Macaulay's onslaught in the *Edinburgh Review* for April 1830.

Montgomeryshire, an inland county of North Wales, 40 miles long and 35 broad, bounded NE. and NW. by the counties of Denbigh and Merioneth, E. by Shropshire, and S. and SW. by Radnorshire and Cardiganshire. Area, 796 sq. m., or 510,110 acres, of which more than one-third is permanent pasture, and about one-ninth under tillage. Pop. (1801) 47,978; (1831) 65,700; (1881) 65,718; (1911) 53,146; (1921) 18,324. Its surface is most barren, and in places mountainous, Plinlimmon (2469 feet), on the Cardiganshire border, the Berwyn Mountains in the NE., and the Breidden Hills—some 12 miles E. of Shrewsbury—being the principal elevations; but towards the English border its character changes, and the predominating feature is that of a series of fertile and well-wooded valleys, in which grain of all kinds, but chiefly oats, is raised, and a small area is under cultivation as fruit orchards. On the uplands the soil is poor, and principally adapted for pasturing the large flocks of sheep reared thereon. The Severn, with its tributary the Vyrnwy, and the Dovey—alike noted for their fishing—are the most important rivers, whilst Offa's Dyke (q.v.) traverses the south-east corner of the county. The mineral wealth of Montgomeryshire is not great, but lead and zinc are mined, and slates, slabs, and limestone quarried. Of manufactures, that of Welsh flannel at Newtown is the most extensive. The county contains the municipal boroughs of Montgomery, Llanfyllin, Llanidloes, and Welshpool. One representative is returned to the House of Commons for the county, as was also (till 1918) one for the Montgomeryshire district of boroughs—viz. Llanfyllin, Llanidloes, Machynlleth, Montgomery, Newton, and Welshpool, which, too, are the chief towns.—The *county town*, Montgomery, with a ruined castle, is 7 miles S. of Welshpool; pop. 1000.

Month. This, the earliest of the natural cycles to be observed, was at first reckoned from new moon to new moon. That period is now called a *lunation* by astronomers to distinguish from *sidereal month*, the time in which the moon passes round the ecliptic to the same star, and from the *tropical month*, reckoned from the moon's passing the equinox till she again reaches it. Those three periods are also called, respectively, synodic month = 29.5306 days, stellar month = 27.3217 days, and periodic month = 27.3216 days. The first, or 'lunar month' proper, consists of 29 days, 12 hours, 44 minutes, 3 seconds. The 'solar month' is the time which the sun takes to pass through 30° (see *CALENDAR, CHRONOLOGY*). From the month, by subdivision, was obtained the week, used by the Chaldeans, Indians, Egyptians, and others from prehistoric times; and as soon as the year became an object of measurement there were numberless attempts to reconcile the solar computation of time with the lunar. The Attic year was of twelve months, alternately 29 and 30 days long, each month being divided into three decades. The Jews and (in part) the Mohammedans still reckon by lunar months of 29 and 30 days, and therefore the Jews, like the ancient Greeks, insert an intercalary or 'embolismic' month. The French republicans in 1793 divided the year into twelve months of 30 days, with five odd days (six in leap year) to be utilised as national festivals, each month being subdivided into three decades of 10 days each, as with the ancient Greeks. Another distribution of the months has since been suggested, should such opportunity again occur—viz.: 1st, 3d, 5th, 7th, 9th, 11th months, each 30 days; 2d, 4th, 6th, 8th, 10th months, each 31 days; and the remain-

ing month 30 days in the ordinary year and 31 in leap year. The existing 'calendar' or 'civil' months are as irregular in length as they were left by the Romans; the 4th, 6th, 9th, and 11th having 30 days, the second 28 days (or 29 in leap year), and the seven others 31 days. To complicate this disorder, a month in English law is 'a lunar month or 28 days unless otherwise expressed;' 'a lease for twelve months is only for 48 weeks' (Blackstone, ii. 141). Besides the archaic division of the month into four, as already mentioned, the early Greeks of Homer's time and previously seem to have had only two parts, the earlier half and the 'waning half;' and a trace of that probably remained in the Roman *Ides*, the middle day.

Montholon, CHARLES TRISTAN, MARQUIS DE, was born at Paris, 1783. Having served in the navy, he entered the army, and was severely wounded at Wagram. Napoleon made him his chamberlain in 1809. During the Hundred Days Montholon was Napoleon's adjutant-general. He accompanied his master to St Helena, and along with Gourgaud published *Mémoires pour servir à l'Histoire de France sous Napoléon* (8 vols. 1822–25). As chief of the staff to Louis Napoleon in 1840, he was condemned to twenty years' imprisonment; he regained his freedom in 1848, having published in 1846 *Récits de la Captivité de Napoléon* (2 vols.). He died 24th August 1853.

Monthyon. See MONTYON.

Monti, VINCENZO (1754–1828), an Italian poet of the classical school, anti-French, Napoleonist, pro-Austrian in turn. He was professor at Pavia, and, under Napoleon, state historiographer.

Montia, or BLINKS, a genus of Portulacaceæ. The only species (*M. fontana*), a small variable succulent herb of world-wide range, grows in water and wet places. It has opposite leaves, and cymes of small inconspicuous flowers, often cleistogamic. It is eaten as a salad.

Monticelli, ADOLPHE (1831–85), a noteworthy modern painter, 'creator of the phantom genre,' was born at Marseilles, studied at Paris, where he lived mainly till 1870. He subsequently settled in Marseilles, and died there in poverty. His paintings fall into three periods, of which the last and most characteristic is notable for masses of warm and gorgeous colouring, with vague, almost invisible figures—nymphs dimly discernible in luxuriant green meadows against a background of glorious cloud masses.

Montjoie St Denis, the French war-cry, old at least as Wace's day (12th century), from the hill near Paris on which St Denis (q.v.) underwent the joy of martyrdom. See *HERALD*.

Montjuich. See BARCELONA.

Montluçon, a town in the French department of Allier, on a castle-crowned hill whose base is washed by the Cher, 202 miles S. of Paris. It owes its rapid development to the Commentry coalfield, and has large iron, plate-glass, and chemical works. Pop. 36,000. Nérès-les-Bains, 18 miles SE., is the *Nerionagus* of the Romans—of whom many traces are left—and since 1821 has again risen into repute through its warm alkaline mineral waters (126° F.).

Montmartre. See PARIS.

Montmédy, a town in the French department of Meuse, 25 miles N. of Verdun and 31 miles by rail SE. of Sedan, consists of two portions, the citadel and upper town overlooking the lower town, which lies in the valley of the Chiers, a tributary of the Meuse. Built and fortified in 1235, it was taken by the French in 1542, 1555, 1596, and 1657; they, after it was definitely assigned to them by the peace of the Pyrenees (1659), had it recon-

structed and re-fortified by Vauban. It was, however, captured by the Germans in 1815, in 1870, and again (after destruction of its defences by the French) in 1914.

Montmorency, a river of Quebec, a tributary of the St Lawrence, famous for its beautiful falls, 8 miles NE. of Quebec. Here the stream is 100 feet wide, and the falls have a sheer descent of 250 feet.

Montmorency, ANNE, first DUC DE, Marshal and Constable of France, born 15th March 1492, belonged to one of the oldest and greatest of the noble families of France. Brought up along with Francis I., he distinguished himself by his gallantry and military skill at Marignano (1515) and in the defence of Mézières, and was taken prisoner along with his sovereign in the battle of Pavia (1525). In consequence of his efforts to win his master freedom, and his successful warring against the emperor's armies, he was made Constable in 1538; but, being suspected by the king of siding with the Dauphin against him, he was banished from court in 1541. On the accession of Henry II. (1547) he was restored to his former position and dignities. In 1557 he commanded the French army which suffered the terrible defeat of St Quentin at the hands of the Spaniards, in which he was again taken prisoner. During the minority of Charles IX. Montmorency, with the Duke of Guise and the Marshal St André, composed the triumvirate which opposed the influence of Catharine de' Medici. In 1562 he commanded the royal army against the Huguenots at Dreux, and was taken prisoner a third time. In the following year he drove the English out of Havre. He again engaged Condé at St Denis (1567), but received a fatal wound, of which he died at Paris on the following day, 11th November 1567. See *Life* by Decrue (2 vols. Paris, 1885-89).

Montmorency, HENRI, DUC DE, grandson of the famous Constable de Montmorency, was born at Chantilly, 30th April 1595. His godfather was Henry IV., who always called him his 'son.' When he was seventeen years of age Louis XIII. made him admiral and viceroy of Canada, and in the following year governor of Languedoc. During the religious wars of 1621 and the following years Montmorency commanded the Catholics in the south against Rohan, was almost captured at the siege of Montpellier (1622), took the islands of Ré and Oléron from the defenders of Rochelle (1625), and penetrated into Piedmont (1630). But Richelieu, jealous of his popularity, provoked him into rebellion along with the king's brother, Gaston, Duke of Orleans. Marshal Schomberg was sent against him, defeated him at Castelnaudary, and took him prisoner. Montmorency, covered with wounds, was carried to Toulouse, sentenced to death by the parliament, and, notwithstanding the intercession of King Charles I. of England, the pope, the Venetian Republic, and the Duke of Savoy, was beheaded, 30th October 1632. Montmorency was distinguished for his amiability and the courtesy of his manners, as well as for his valour.

Montoro, a town of Spain, on the Guadalquivir, 26 miles ENE. of Córdoba; pop. 14,000.

Montpelier, the capital of Vermont since 1805, is on the Winooski or Onion River, 206 miles by rail NNW. of Boston. It contains a handsome granite state-house, with a statue of Ethan Allen, and has some mills and tanneries. Pop. 7000.

Montpellier, the capital of the French department of Hérault, on the river Lez, 6 miles from the sea and 31 SW. of Nîmes. Pop. (1872) 54,466; (1911) 80,230; (1921) 81,548. Near the centre of Languedoc, on the great route from Italy and Pro-

vence to Spain, with its seaport at a point offering the shortest land-route not only to all parts of Languedoc, but to north France, Montpellier's position was a highly favourable one during the middle ages. Hence alike its commercial and intellectual importance, and its stormy history, during which it was sometimes independent, and sometimes under the suzerainty of Aragon or Navarre, before finally becoming a possession of the French crown in 1392. Its schools of medicine, law, and arts, developing during the 12th and 13th centuries, were formally constituted a university by a papal bull in 1289, at which time the schools of law and medicine (the latter founded by Arabian physicians) rivalled those of Paris. In the following century Petrarch was a student at the law school, and Arnaud de Villeneuve, the alchemist and physician, was teaching in the medical school. With such a geographical position Montpellier was easily stirred by the Renaissance. Rabelais and Rondelet the anatomist both graduated in medicine in 1537; Casaubon was made Greek professor in 1586. After Rondelet there is a continuity almost unique in the history of science. A pupil of his founded the famous botanic garden (the oldest in France) in 1593; other pupils, Lobel, Clusius, the brothers Bauhin, were highly distinguished amongst the earlier botanists (see BOTANY). At the end of the 17th century (during which Clarendon and Locke had been residents), Magnol again made Montpellier the centre of the science, and reckoned among his pupils Tournefort and the elder De Jussieu. De Candolle also wrote here some of his principal works, and laid out the first botanic garden upon the natural system in 1810. The medical school had also a notable history; and a new period of activity is indicated by the celebration of the sixcentenary of the university (1890), with its reorganisation upon the fullest scale of equipment. The town has also an important picture-gallery and library.

A centre of wine production, upon which its present prosperity depends, Montpellier suffered greatly by the phylloxera; but it was here that the cure of grafting French vines upon American stocks was earliest applied. The new School of Agriculture, chiefly devoted to the practical study of wine and silk culture, is very flourishing. Of the mediæval town little remains, its fortifications and most of its buildings, save the cathedral and the adjoining bishop's palace (which now houses the school of medicine), having been destroyed in the religious wars, in the Revolution, or by municipal improvements. The older streets are crooked and narrow, but afford better shelter from the sun, and from the chilling *mistral*, than do the modern ones. The chief modern buildings are the theatre and law-courts; but the principal glory of the town is its two great terraces, forming public promenades overlooking the undulating country dotted with innumerable *mazets* or country cottages, and in the distance the Mediterranean, Cevennes, Pyrenees, and Alps. See books by Duval Jcuve and Aigrefeuille.

Montpensier. See BOURBON.

Montreal, the principal city of the Dominion of Canada, is the centre of Canadian commerce, of Canadian banking, and of the extensive system of railways by which the country is covered. It is built on the south-east side of an island formed by the junction of the Ottawa River with the St Lawrence, and may be said in general terms to be situated on the northern bank of the St Lawrence. The city is about 4 miles long and 2 wide, the Central Mountain rising in the rear narrowing the city at its base for some distance. It is not the

political capital of the province of Quebec, but it exerts an immense political influence, and practically not only directs the political business of Quebec, but exerts also by means of its banks, its manufactures, and its great importing and distributing commercial houses a great influence on the public policy of the Federal Government. It is also the seat of the greatest universities, hospitals, convents, and seminaries in all Canada. Finally it is during the season of navigation—i.e. from May to November—the great maritime port of the Dominion, many transatlantic steamship companies making it one of their headquarters; while a lake and river and coast navigation of great activity increases and diversifies the business of the city. It is nearly 1000 miles from Montreal to the ocean proper, and 250 to the first salt water at Three Rivers; and Montreal is 300 miles nearer Liverpool than is New York. Pop. (1871) 107,225; (1881) 140,747; (1901) 267,730; (1911) 470,480; (1921) 618,506, with suburbs about 850,000. Over half are of French descent; of the rest, the Irish are more numerous than those of English and Scottish descent.

The growth of the commerce of Montreal has been very remarkable. The 1500 miles of the St Lawrence River contribute; and the great graving-dock (1913) is proving very useful. For the great Victoria Railway Bridge across the St Lawrence, rebuilt in 1898-99, see BRIDGE. The canal system which finds its outlet at Montreal is remarkable. By means of the canals Montreal is enabled to touch and handle the trade of Duluth and Fort William on Lake Superior, of Chicago and Milwaukee on Lake Michigan, Collingwood and Goderich on Lake Huron, Buffalo and Cleveland on Lake Erie, Hamilton, Toronto, Kingston, and Oswego on Lake Ontario. These canals afford a continuous course of water-communication extending from the Straits of Belle Isle to Port Arthur at the head of Lake Superior, a distance of 2260 miles. Montreal, therefore, looks forward with some misgiving to the project for deep-water communication with the lakes, by which need for transshipment would end. See CANAL. The Canadian National, the Canadian Pacific, and other railways open up by means of various connections the whole railway-system of the United States and Canada, and the Canadian Pacific Railway has a through line from Montreal to Vancouver City in British Columbia, a distance of 2906 miles. Thousands of hands are employed in the boot and shoe manufacture, in clothing-factories, in tobacco-factories, and in the workshops of the railways. There are also rubber-factories, sawmills, sack-factories, tool-factories, silk-factories, cotton-mills, and an endless variety of small industries which receive encouragement from the protection afforded by the tariff.

Of the Episcopal churches, Christ Church Cathedral has a tower 224 feet in height, and St George's one of 230 feet. The Catholic churches are numerous, and some of them splendid: St Peter's Church is a repetition on a smaller scale of the church at Rome; Notre Dame holds 10,000 people; St Patrick's is the church of the Irish Catholics. In the French churches the preaching is generally in the French language. Education in Montreal is conducted under the law of the province of Quebec. It is denominational in character, the vast majority of the schools being of course Roman Catholic. The Protestant schools are under the control of a special board. The taxes on Catholics go to the Catholic schools, the taxes on Protestants to Protestant schools. McGill University, which obtained its charter in 1821, has been an active establishment since 1852; the University of Montreal (Roman Catholic) has taken over and developed the Mon-

treau branch of Laval University of Quebec; the seminary of St Sulpice, founded in 1657, is a theological institution; the Presbyterian College, chartered in 1865, is well endowed; the Wesleyan Theological College was founded in 1873; and others in the long list are the Congregational College, the Anglican Diocesan College, St Mary's College, founded in 1848 by the Jesuits, the academic hall of which holds 1200 people, the Jacques Cartier Normal School, under the control of the provincial government, the Christian Brothers' Schools, the schools and convents of the congregation of Notre Dame, the schools and convents of the Sacred Heart. McGill College Library, the Advocates' Library, the Presbyterian College Library, the Mechanics' Institute, the Fraser Institute, and the Y.M.C.A. have libraries of some value. The *Quebec Gazette* (1764) was the first paper published in Canada; the *Montreal Gazette* (1778) is the next oldest, and is a leading journal still. There are musical, art, and historical associations also which maintain in Montreal a taste for art, literature, and science not common in colonial commercial cities. Among the chief philanthropic institutions are the General Hospital, the Protestant House of Industry, the Y.M.C.A. building, the Dispensary, the Gray Nuns' Hospital (1755), which is also a foundling hospital, the Hôtel Dieu (1644).

History.—Montreal was purchased from the president of the Hundred Associates of France, a trading corporation, by Abbé Olier and Dauversière, who were moved by religious enthusiasm to establish institutions there; it was actually founded by Maisonneuve, the leader and military head of the enterprise of Olier and Dauversière, who landed at Montreal (*Ville-Marie de Montréal*) on the 18th May 1642. The early history of the city was one of continuous struggles against the Iroquois Indians, by whom the whole island was more than once devastated up to the very palisades of the town's defences; and in 1660 the Indians almost exterminated the population not actually within the feeble defences. In 1722 the city was fortified with a bastioned wall and ditch. In September 1760, the year following the capture of Quebec by Wolfe, Montreal was surrendered by the French governor, De Vaudreuil, to the British, under Lord Amherst and General Murray. In 1776-77 the city was occupied by the invaders from the revolted colonies, who did their best to coerce or cajole the Canadians into joining in the rebellion. In 1777 the British forces advanced from Quebec, and Montreal was evacuated by the invaders. Since that time the history of the city has been peaceful. The war of 1812-14 did not disturb its progress. The rebellion of 1837 for a moment ruffled its political serenity; but all its modern history has been the history of constitutional development, of business progress, of educational advancement, and of growth in population.

Montreuil-sous-Bois, an eastern suburb of Paris in the department of the Seine. It is noted for its porcelain works. Pop. 51,000.

Montreux, a group of villages on the north shore of the Lake of Geneva, 15 miles by rail SE. of Lausanne. The name properly belongs to one small hamlet, but is popularly extended so as to include the adjoining villages of Clarens, Vernex, Veytaux, &c. The beautiful situation and mild climate of 'the Swiss Nice' attract many invalids to the place, which abounds with hotels and *pensions*. Near it is the castle of Chillon. Pop. 17,000.

Montrose, a seaport of Forfarshire, 76 miles NNE. of Edinburgh and 42 SSW. of Aberdeen. It stands on a level peninsula between Montrose Basin (a tidal loch, measuring 2 by 1½ miles, but

almost dry at low-water) and the mouth of the river South Esk. A fine suspension bridge (1829), 432 feet long, leads to Inchbrayock or Rossie Island, in the Esk's channel, and is continued thence by another bridge; and there is also a railway viaduct (1883). Montrose has a plain town-hall (1763-1819); a large parish church (1791-1834), with a steeple 200 feet high; an academy (1820); a lunatic asylum (1868), 2 miles NNW.; good links; and a wet dock (1840). The foreign trade—timber its staple—is chiefly with the Baltic. Flax-spinning is the principal industry; and ropes, canvas, &c., are also manufactured. Montrose was the birthplace of Robert Brown, botanist; Joseph Hume; Sir Alexander Burnes; and Paul Chalmers, R.S.A. It has memories, too, of Edward I., the two Melvilles, the Great Marquis, the Old Pretender, Dr Johnson, and Lola Montez. A royal burgh since 1352 and earlier, it unites with Arbroath, Brechin, Forfar, and Bervie to return one member to parliament. Pop. (1851) 15,238; (1921) 10,979.

Montrose, JAMES GRAHAM, MARQUIS OF, belonged to a family which can be traced back to the year 1128, and which since 1325 had been settled at Old Montrose, in Maryton parish, Forfarshire, near Montrose town. It had been ennobled with the titles of Lord Graham (1451) and Earl of Montrose (1505); and three of its members had fallen at the battles of Falkirk, Flodden, and Pinkie; whilst another, Sir William Graham, early in the 15th century married for his second wife Mary, daughter of Robert III.—a marriage from which sprung the Grahams of Claverhouse. John, third Earl of Montrose, was chancellor and, after James VI.'s accession to the English crown, viceroy of Scotland. His successor, John, married Lady Margaret Ruthven, eldest sister of the unfortunate Earl of Gowrie; and the issue of this union was five daughters and one son, James, the 'great marquis,' who was born in 1612 at Old Montrose. His mother died in 1618, his father in 1626. Next year the young earl was sent to the university of St Andrews by his guardian and brother-in-law, Archibald Lord Napier, son of the famous inventor of logarithms. He was proficient in all field-sports, and an apt if not ardent student, besides exhibiting a genuine love of literature, which his stormy after-life never destroyed. In 1629 he married Magdalene Carnegie, daughter of the first Earl of Southesk, and he lived at Kinnaird Castle, his father-in-law's seat, till in 1633, on attaining his majority, he left Scotland to travel in Italy, France, and the Low Countries.

On his way home, in 1636, he had an audience with Charles I., but, owing to the machinations of the Marquis of Hamilton, was coldly received; and he had not been long back in Scotland before by the 'canniness of Rothes' he was 'brought in' to the ranks of the king's opponents, at this time comprising the great mass of the Scottish nation. Montrose returned in the very year (1637) when the tumults broke out in Edinburgh on the attempt to introduce Laud's Prayer-book; and he was one of the four noblemen selected to compose the 'Table' of the nobility, which, along with the other Tables of the gentry, the burghs, and the ministers, drew up the famous National Covenant (q.v.). In the summer of 1638 he was despatched to Aberdeen, to coerce it into subscription; and in 1639 he made three military expeditions thither. On the first occasion (30th March) he employed conciliation; Baillie laments his 'too great' humanity. On the second (25th May) he imposed on the city a fine of 10,000 merks, but, though his soldiers committed some acts of pillage, he resisted the importunities of the Covenanting zealots to give 'Meroz' to the flames, and Baillie again

complains of 'his too great lenity in sparing the enemy's houses.' The arrival at Aberdeen by sea of the Earl of Aboyne, Charles's lieutenant of the north, with reinforcements, caused Montrose to retreat, followed by the earl and the Gordon Highlanders; but at Meagra Hill, near Stonehaven, on 15th June, he won a complete victory, and four days later, after storming the Bridge of Dee, he was once more master of Aberdeen. The citizens expected some bloody punishment for their well-known Episcopalian leanings, but again Montrose agreeably disappointed their fears, again to be upbraided by the Committee of Estates for not having burned the town.

News now arrived of the 'pacification of Berwick,' and terminated the struggle in the north. Charles invited several of the Covenanting nobles to meet him at Berwick. Among those who went was Montrose; and the Presbyterians dated what they regarded as his apostasy from that interview. His political position was certainly different after his return. In the General Assembly which met in August 1639 he showed symptoms of disaffection towards the Covenant; and one night, it is said, a paper was affixed on his chamber-door, '*Invictus armis, verbis vincitur.*' In the second Bishops' War, when, on 20th August 1640, 25,000 Scots crossed the Tweed, Montrose was the first to plunge into the stream; but that very month, with eighteen other nobles and gentlemen, he had entered into a secret engagement at Cumbernauld against the dictatorship of Argyll, to whom and the zealots Montrose was as hostile now as he ever had been to Hamilton and the 'sometime pretended prelates.' It leaked out that he had been secretly communicating with the king; and when the Scottish parliament met (November 1640) he was cited to appear before a committee. The affair of the 'Cumbernauld Bond' was brought up; but nothing came of it, though some of the fiery spirits among the clergy 'pressed,' says Guthrie, 'that his life might go for it.' Next June Montrose with three others was accused of plotting against Argyll, and confined till November in Edinburgh Castle. Clarendon's story that Montrose, about this period, offered to the king to assassinate Argyll and Hamilton may safely be set aside; but to Hamilton he owed the rejection of his two proposals in the following year to raise the royalist standard in the Highlands.

In 1644, however, he quitted his forced inaction at Oxford, where he had been residing with Charles, and, disguised as a groom, made his way into Perthshire, with the rank of lieutenant-general in Scotland and the title of Marquis of Montrose. At Blair-Athole he met 1200 Scotto-Irish auxiliaries under Alaster Maccoll Keitache Macdonell ('Col-kitto'), and placed himself at their head, the clans quickly rallying round him. Marching south, on 1st September he fell on the Covenanting army, commanded by Lord Elcho, at Tippermuir, near Perth, and gained a signal victory. He next defeated a force of Covenanters at Aberdeen (13th September), and took possession of the city, which was this time abandoned for four days to all the horrors of war. The approach of Argyll, at the head of 4000 men, compelled Montrose, whose forces were far inferior in numbers and discipline, to retreat. He plunged into the wilds of Badenoch, recrossed the Grampians, and suddenly appeared in Angus, where he wasted the estates of more than one Covenanting noble. Having obtained fresh supplies, he once more returned to Aberdeenshire, with the view of raising the Gordons; narrowly escaped defeat at Fyvie in the end of October; and again withdrew into the fastnesses of the mountains. Argyll, baffled, returned to Edinburgh, and threw up his com-

mission. Montrose, receiving large accessions from the Highland clans, planned a winter campaign, marched south-westward into the country of the Campbells, devastated it frightfully, drove Argyll himself from his castle at Inveraray, and then wheeled north intending to attack Inverness. The 'Estates' at Edinburgh were greatly alarmed, and, raising a fresh army, placed it under the command of a natural son of Sir William Baillie of Lamington. He arranged to proceed by way of Perth, and take Montrose in front, while Argyll should rally his vast array of vassals, and fall on him in the rear. The royalist leader was in the Great Glen of Albin, the basin of the Caledonian Canal, when he heard that Argyll was following him. He instantly turned on his pursuer and surprised and utterly routed him at Inverlochy, 2d February 1645. Fifteen hundred of the Campbells were slain, only four of Montrose's men. He then resumed his march northward, but did not venture to assault Inverness, his wild mountaineers being admirably fitted for rapid irregular warfare, but not for the slow work of beleaguering. So, directing his course eastward, he passed with fire and sword through Moray and Aberdeenshire. Baillie and Hurry, his lieutenant, were at Brechin, but Montrose by a dexterous movement eluded them, captured and pillaged Dundee (3d April), and escaped safely into the Grampians. On 4th May he routed Hurry at Auldearn, near Nairn, and on 2d July inflicted a still more disastrous defeat on Baillie himself at Alford in Aberdeenshire. 'Before the end of the summer,' he sent word to Charles, 'I shall be in a position to come to your Majesty's aid with a brave army;' and towards the end of the month he marched southward with upwards of 5000 men. He was followed by Baillie, who picked up reinforcements by the way, and who on 15th August again risked a battle at Kilsyth, but was defeated with frightful loss, 6000 of the Covenanters being slain. This, the last and most signal of Montrose's six splendid victories, seemed to lay Scotland at his feet, but the clansmen slipped away home to secure their booty, and Aboyne withdrew with all his cavalry. Still, with 500 horse and 1000 infantry, he had entered the Border country, when, on 13th September, he was surprised and hopelessly routed by 6000 troopers under David Leslie at Philiphaugh, near Selkirk. Escaping to Athole, he again endeavoured, but vainly, to raise the Highlands; and on 3d September 1646 he sailed for Norway, whence he proceeded to Paris, Germany, and the Low Countries.

Here it was that news reached him of Charles I.'s execution, whereat he swooned, and then reviving, 'swore before God, angels, and men to dedicate the remainder of his life to the avenging the death of the martyr.' So, on behalf of Charles II., he undertook a fresh invasion of Scotland, and from Orkney passed over to Caithness, his little army almost annihilated by shipwreck. Neither gentry nor commons would join him; but he pushed on to the borders of Ross-shire, where, at Invercharron, his dispirited remnant was cut to pieces by Strachan's cavalry, 27th April 1650. He fled into the wilds of Sutherland, and was nearly starved to death, when he fell into the hands of Macleod of Assynt, who sold him to Leslie. He was conveyed with all possible contumely to Edinburgh, where, dressed like a gallant bridegroom, he was hanged in the High Street, near the Cross, on a lofty gallows, 21st May 1650. Eleven years afterwards his mangled remains were collected from the four airts and buried in St Giles's, where a stately monument was reared to him in 1888. He left a son, James, the 'good Marquis' (c. 1631-69), whose grandson in 1707 was created Duke of Montrose.

Montrose's few poems, all burning with passionate loyalty, are little known, save the one famous stanza, commencing, 'He either fears his fate too much.' That has the right ring, one would think; and yet its ascription to Montrose is doubtful, first put forward in Watson's *Collection of Scots Poems* (1711). There are four portraits of Montrose—by Jameson (1629 and 1640), Dobson (1644), and Honthorst (1649). Of the inner man the finest estimate is Gardiner's: 'When once he had chosen his side, he was sure to bear himself as a Paladin of old romance. If he made any cause his own, it was not with the reasoned calculation of a statesman, but with the fond enthusiasm of a lover. When he transferred his affections from the Covenant to the king, it was as Romeo transferred his affections from Rosaline to Juliet. He fought for neither King nor Covenant, but for that ideal of his own which he followed as Covenanter or Royalist. He went ever straight to the mark, impatient to shake off the schemes of worldly-wise politicians and the plots of interested intriguers. Nature had marked him for a life of meteoric splendour, to confound and astonish a world, and to leave behind him an inspiration and a name which would outlast the ruins of his hopes.'

See the Latin *Memoirs* by his chaplain, Dr Wishart (Amst. 1647; trans. by Murdoch and Morland Simpson, 1893); Mark Napier's *Memoirs of Montrose* (1838; 4th ed. 1856); Lady V. Greville's *Montrose* (1886); Mrs Pryce's *Great Marquis* (1912); J. Buchan's *Montrose* (1913); and Gardiner's *History of England, Great Civil War, and History of the Commonwealth and Protectorate*.

Montserrat (Lat. *Mons Serratus*, so named from its saw-like outline), a mountain of Catalonia, in north-east Spain, 30 miles NW. of Barcelona. Its height is 4055 feet; and 'its outline,' says Ford, 'is most fantastic, consisting of cones, pyramids, buttresses, ninepins, sugar-loaves.' The pious Catalonians aver that it was thus shattered at the Crucifixion. Every rift and gorge is filled with box-trees, ivy, and other evergreens. From the topmost height the eye wanders over all Catalonia. The mountain, however, owes its celebrity to the Benedictine abbey built half-way up it, with its wonder-working image of the Virgin, and to the thirteen hermitages formerly perched like eagles' nests on almost inaccessible pinnacles. In 1811 the French, under Suchet, plundered the abbey, burned the library, shot the hermits, and hanged the monks (who had given shelter to their emigrant brethren at the Revolution). The place suffered still more in 1827, when it became the stronghold of the Carlist insurrection.

Montserrat, one of the Lesser Antilles, belonging to Britain, lies 27 miles SW. of Antigua. It is about 11 miles in length, 7 in breadth, and has an area of 32 sq. m. Pop. 12,000, of whom Plymouth, the chief town, has 1700. The surface is very mountainous (3000 feet), and heavily timbered. Sugar, limes and lime-juice, cotton, cocoa, Castillea rubber, coffee, arrow-root, and papain are the principal products. The island, governed by a commissioner and a nominated legislative council, is the healthiest in the West Indies.

Mont St Michel. See ST MICHEL.

Montucla, JEAN ÉTIENNE (1725-99), an eminent mathematician, born at Lyons, held some minor government posts, and wrote the first name-worthy *Histoire des Mathématiques*.

Montyon Prizes, rewards for signal instances of disinterested goodness discovered throughout the year, awarded by the French Academy, according to the will of Jean-Baptiste-Robert Auger, Baron de Montyon (1733-1820), who bequeathed £120,000 to public hospitals, and the remainder of

his fortune to give sums of money to poor patients on leaving Paris hospitals, and to found the prizes since connected with his name. Already in 1782 he had originated the prize of virtue, but on his return to France in 1815 he arranged the scheme in its final form. The Academy of Sciences awards annually a prize of 10,000 francs for means of making any mechanical occupation more healthy, another of equal value for improvements in medicine and surgery; while the Forty themselves award the prize of virtue, and another to the writer of the work likely to have the greatest beneficial influence on morality—both alike of 10,000 francs a year.

Monuments. The Ancient Monuments Protection Acts of 1882, 1898 (Ireland), 1900, 1910, 1913, constitute the Commissioners of Works guardians of certain monuments in Great Britain and Ireland; and provide for their being made guardians of as many more as the owners shall put under their care, and for acquisition by gift, purchase, or bequest. Owners retain all rights save as regards injuring or defacing the monuments; any person defacing or injuring them is liable to a fine not exceeding £5, or imprisonment for a month. The Commissioners, the specially appointed Inspector of Ancient Monuments, and their workmen are to have access to do what may be necessary to protect the monuments. In France famous castles and churches, as well as dolmens, &c., are among the *monuments historiques* protected by law. Many of these and other monuments at home and abroad are dealt with in special articles. See

Monza (anc. *Modetia*), a town of Italy, on the river Lambro, 9 miles by rail NNE. of Milan. The ancient capital of the Lombard sovereigns, it owed much of its early importance, and its chief public edifices, to Theodelinda; and in the middle ages, in spite of thirty-two sieges, it was conspicuous for the wealth of its numerous citizens and nobles, and the extent of its cloth-trade. The cathedral, founded in 595 by Theodelinda, contains many interesting relics of this great queen. Humbert I. was assassinated here by Bressi, 29th July 1900. The famous Iron Crown, removed to Vienna in 1859, was restored in 1866 (see CROWN). The town has also an interesting town-hall (1293), a royal palace (1777), given to the nation in 1919, and manufactures of cottons, hats, leather, &c. Pop. 57,000.

Moody, DWIGHT LYMAN, evangelist, was born at Northfield, Massachusetts, 5th February 1837, was for a while a shopman in Boston, and in 1856 went to Chicago, where he engaged with remarkable success in missionary work. In 1870 he was joined by Ira David Sankey, who was born at Edinburgh, Pennsylvania, 28th August 1840. In 1873 and 1883 they visited Great Britain as evangelists; but the main centre of their evangelistic and educational work was Northfield, Mass., where Moody died 22d December 1899. A vigorous, striking, unconventional speaker, and a worker of extraordinary energy, he published some volumes of sermons and other works. The standard Life of him is by his son (1900).

Moody, WILLIAM VAUGHN (1869-1910), poet and dramatist, born at Spencer, Indiana, graduated from Harvard, and was instructor in English at Chicago University. His first published work, *The Masque of Judgment* (1900), was one of a trilogy of philosophic dramas in blank verse, the others being *The Death of Eve* (unfinished) and *The Fire-*

Bringer. In 1901 appeared *Poems*, including strenuous lyrics and patriotic stanzas (e.g. 'On a Soldier Fallen in the Philippines'), instinct with lofty indignation against injustice and wrong. His prose play, *The Great Divide* (1906), achieved instant success; not so his mystical prose drama, *The Faith Healer* (1909). A complete edition of the *Poems and Poetic Dramas* (2 vols.) was issued in 1912.

Mooltan. See MULTAN.

Moon, the satellite of the earth, which ranks among the larger satellites of the solar system, being an almost perfect sphere of 2158 miles diameter. The mean distance between its centre and that of the earth is 238,870 miles. As compared with the earth, its diameter is .273, its surface .074, and its volume .0203. The ratio of its mass to that of the earth is 1:81.53; thus its mean density is .60 that of the earth, or 3.5 times that of water. Gravity at the moon's surface is one-sixth of its amount on the earth. The moon makes a complete revolution round the earth in one month, but as it rotates about its axis in the same period, it always presents the same face to us. Its orbital velocity about the

Fig. 1.—Comparative Sizes of the Earth and Moon.

earth is 2270 miles per hour, and its equatorial velocity of rotation 10 miles per hour. Presenting as large a surface to the eye as the sun, and changing both its form and position with great rapidity, the moon was studied very early in the history of civilisation, and proved the most useful of the heavenly bodies for the measurement of time. Its motions have been most carefully observed in modern times in order that its position in the sky may be calculated beforehand, and enable the traveller and navigator to determine longitude (see LATITUDE AND LONGITUDE).

Every month the moon waxes and wanes, changing from a thin crescent to a half-moon, from a half to a full, and from a full back again to a thin crescent. These changes in the moon's appearance are called its phases, and observation shows that as the phase changes the angle between the directions of the sun and moon changes also. The new moon is always seen in the west, near the setting sun; when it is half illuminated its direction is at right-angles to that of the sun; when full it is in a direction directly opposite to the sun. Further, at new moon it sometimes comes between the earth and the sun, causing an eclipse of the sun; and at full it sometimes is screened from the sunlight by the earth's shadow, and is itself eclipsed (see ECLIPSE). The explanation of the changes of phase, given by Aristotle (384-322 B.C.) and probably surmised much earlier, is: The moon is a spherical body which moves round the earth; it is not self-luminous, but is illuminated by the distant sun. When the moon is a thin crescent only a small portion of the illuminated half is turned towards the earth, while when it is full the whole of the illuminated half is presented. When the moon is crescent the rest of the disc is frequently seen at the same time,

faintly illuminated by light from the earth. This interesting phenomenon, known as 'the old moon in the arms of the new,' confirms the explanation which has been given.

If the moon be observed on consecutive nights it will be seen that its position among the stars has shifted considerably. In the course of a month it makes a complete circuit of the stars. Each day, like the sun and stars, it appears to move from east to west; but this movement, due to the rotation of the earth on its axis, may for the present be left out of consideration. Suppose the sky could be seen from the earth's centre, stars would be seen dotted all over and apparently on the surface of a distant sphere. The sun, moon, and planets would be seen all near a *great-circle* of this sphere, or circle cut from the sphere by a plane through its centre. This great-circle, called the *Ecliptic* (q.v.), passes through certain definite constellations, and may be considered as fixed among the stars. The sun moves round the ecliptic in one year. The orbit of the moon does not agree exactly with the ecliptic, but is a great-circle near to it—i.e. cutting it at a very small angle at two opposite points, and reaching its greatest distance from the ecliptic, on opposite sides, half-way between these points of intersection. The moon describes its orbit in one month. It makes a complete circuit of the stars in a *sidereal month*. The average length of the sidereal month is 27·32166 mean solar days. But as the sun is also moving along the ecliptic, a longer time elapses before the moon is again in conjunction with the sun. Thus the *synodic month*, or average time from new moon to new moon, full to full, &c., is 29·53059 days. But this is only to be regarded as a rough first approximation to the movement of the moon, which is very complicated and intricate when it is accurately observed. Its orbit is inclined at an angle of $5^{\circ} 8' 40''$ to the ecliptic; but the line of Nodes (q.v.), or intersection of the orbit with the ecliptic, is not fixed. It moves slowly in a retrograde direction, completing its revolution in 18·6 years. Again, the movement of the moon in its orbit is not uniform. On the average an arc of $13^{\circ} 10'$ is described daily, but varies from less than 11° to more than 15° . A considerable part of this want of uniformity is accounted for by the fact that the moon does not describe a circle uniformly about the earth as centre, but an ellipse of eccentricity ·055 of which the earth occupies a focus, moving, in accordance with Kepler's Laws (q.v.), more quickly when near the earth than when more distant. This movement is also detected by measures of the moon's apparent diameter, which varies from $33' 30''$ when the moon is in *perigee* or nearest the earth to $29' 20''$ when in *apogee* or farthest from the earth. This ellipse is not fixed, but its longest axis or line of apsides moves (turns slowly) in a forward direction, completing a revolution in nine years. The motion of the moon was so far analysed by the Greek astronomers, especially by Hipparchus, who discovered the eccentricity—more accurately represented by Kepler as the elliptic character—of the moon's orbit and the motion of the apsides.

The position of the moon in the sky is determined by taking as a foundation the mean motion of the moon in longitude—i.e. along the ecliptic, the mean motions of the node and apse, and adding to these various periodic terms which are now represented trigonometrically. If g denote the moon's anomaly or angular distance from *perigee*, g' the sun's anomaly, and D the angular distance from the sun in the plane of the ecliptic, the five largest inequalities in the moon's longitude are: $+6^{\circ} 17' 2'' \sin g + 1^{\circ} 16' 26'' \sin (2D - g) + 39' 57'' \sin 2D + 12' 49'' \sin 2g - 11' 9'' \sin g'$. The first term is the *elliptic inequality*, discovered

by Hipparchus; the second the *evection*, discovered by Ptolemy; the third the *variation*, discovered by Tycho Brahe; and the fifth the *annual inequality*, also discovered by Tycho; while the fourth term may be regarded as due to Kepler's substitution of the ellipse with the earth as focus for a circle with the earth placed a little out of the centre.

The problem of the moon's motion was revolutionised by the discovery of the law of gravitation. Newton showed that under the attraction of the earth alone the moon would describe an ellipse. The influence of the sun—which, though distant, is very massive—causes Perturbations (q.v.) in this ellipse. Newton showed that the motion of the nodes and apsides and the principal inequalities were attributable to this cause. The problem was then presented of determining deductively the motion of the moon with as great accuracy as could be verified by observation. Newton had used geometrical methods, but the great complication of the problem required analysis for its further development. The first great exponents of the lunar theory were Clairaut and Euler. As observations became more accurate greater demands were made on gravitational theory, and many great mathematicians have applied themselves to this difficult problem. The three most complete theories are those of Hansen, Delaunay, Hill and Brown. Delaunay gives a complete algebraic solution of the problem, but is obliged to use series of slow convergency. Hansen avoids this by using numerical values of some of the quantities involved, such as the eccentricity of the moon's and sun's orbit. His method is thus less general and less interesting from the mathematical standpoint, but in some respects solves the problem with greater numerical accuracy. The method of Hill is algebraic, excepting for one quantity—the ratio of the month to the year, for which a numerical value is taken. Thanks to some very beautiful and ingenious mathematics, this theory is comparatively simple. It has been carried through to completion by E. W. Brown. The attractions of the planets as well as of the sun are included in these works. Hansen constructed tables based on his own theory, and the predictions of the moon's place in the *Nautical Almanac* have been based on these tables since their completion in 1857. Under the direction of Radau, tables were published in 1911 for prediction of the moon's place on Delaunay's theory. These are utilised in the *Connaissance des Temps*, while the British and American nautical almanacs have used Brown's tables from 1923. These theories have almost completely succeeded in predicting the moon's place. There still remain, apparently unaccountable for by theory, two inequalities—one of semi-amplitude, $11' 5''$, with a period of about 270 years; and another of semi-amplitude, $3' 3''$, with a period of about 60 years. The possibility of these terms arising from planetary perturbations has been exhaustively examined and answered in the negative by Radau and Brown.

A point of great interest in the theory of the moon is the *secular acceleration*. In 1693, by examination of the records of ancient eclipses, Halley concluded that the moon's mean motion was increasing at the rate of $12''$ a century; i.e. in each century the moon moved $12''$ more than in the previous century. Laplace investigated the subject theoretically, and accounted for it as the result of a slow change in the eccentricity of the earth's orbit about the sun. In 1853 Adams showed that only half of the amount could be accounted for by this cause. His result was confirmed by Delaunay, and later researches by Brown give $5' 91''$ as the theoretical value of this quantity. The difference between the theoretical and observed values led

to renewed examination of the records of early eclipses by Newcomb, Cowell, and Fotheringham. The indefiniteness of these records makes them difficult to interpret. The discovery in the British Museum of the record of an eclipse at Babylon (identified by Cowell as occurring on 31st July 1063 B.C.) led Cowell to a better determination of the moon's secular acceleration, and the discovery of a small secular acceleration in the movement of the sun. Following Cowell, Fotheringham has given as (*Monthly Notices*, Royal Astronomical Society, December 1920 and April 1923) the conclusion of a very complete discussion of early solar and lunar eclipses and occultations of stars by the moon a value of $10\cdot3''$ per century for the secular acceleration of the moon, and $2\cdot1''$ for that of the sun. The excess of the observed value of the moon's secular acceleration over the calculated value and the secular acceleration of the sun may be explained by a slow lengthening of the day. This is caused by the frictional action of the tides, which acts like a brake on the rotating earth. It has been shown by Taylor and Jeffries (*Monthly Notices*, Royal Astronomical Society, 1920) that shallow seas in which the tides run strongly are most effective in bringing this about. Detailed numerical calculation shows that the Irish Sea will account for one fifty-sixth of the amount required. There seems little doubt that there are sufficient closed areas, such as the English Channel, Behring Strait, Bay of Fundy, and Mozambique Channel, to cause the whole of the hitherto unexplained part of the secular acceleration.

Fig. 2.—The Moon, photographed at Greenwich on 19th April 1899.

The moon's distance from the earth is obtained by observations of its place from two widely separated stations, such as the observatories at Greenwich and the Cape of Good Hope. If observed simultaneously from these stations the moon will not appear to both observers in the same position among the stars, the amount of difference depending on the distance of the moon from the earth at the time. From this difference is deduced the moon's *equatorial horizontal parallax*, or the change in the moon's position among the stars which would be noted by an observer on the equator

when the moon was seen on the horizon, if he shifted his place to the centre of the earth. The mean distance of the moon given above as 238,870 miles is probably less than twenty miles in error.

From the fact that the moon always presents the same face to the earth, it follows that the moon rotates about an axis perpendicular to the ecliptic in the same time as it revolves round the earth—i.e. a little more than twenty-seven days. The axis is not quite perpendicular to the ecliptic but inclined $1^{\circ}30'$ from the perpendicular. Owing to the want of uniformity in the moon's orbital motion and the changes in this orbit, there are slight variations in the face presented to us. At one time and another about $\cdot59$ of the moon's total surface is seen from the earth (see LIBRATION). The figure of the moon is very slightly ellipsoidal, bulging out a little in the direction towards the earth.

From the differences in size, density, and mass we should expect that, while presenting some features of agreement, the moon would differ widely from the earth in physical condition. To the naked eye some peculiarities are obvious. Attentively watching the full moon, we soon become familiar with its irregularly-spotted surface, which *never changes*. It cannot be like the earth, which is often obscured by clouds and mists. The telescope confirms this impression. No changes have been certainly detected by astronomers, and only one, that in the walls of the small crater Linné, has been reasonably suspected. The details of the lunar surface are hard, cold, and glaring in their delineation. The delicate colouring and shade of terrestrial scenery is entirely absent. Its surface appears to consist of bare rock, showing cracks, possibly due to the effects of heat and cold. Nothing like mist, cloud, or vapour has ever been seen, and the inference is drawn that the moon has practically no water or air. Observations of stars occulted by the moon (see OCCULTATIONS) confirm this, and the moon's atmosphere certainly cannot have more than $\frac{1}{100000}$ th of the surface density of our own.

The total amount of light received from the full moon is about $\frac{1}{100000}$ th of that received from the sun. Of the light received by it from the sun about 17 per cent. is reflected. About the same proportion of the heat received is similarly reflected, and the remaining 83 per cent. absorbed. It has been calculated by Poynting and also by Very that during the lunar day—i.e. fourteen of our days—the moon rises to a temperature very near the boiling-point of water. In the lunar night the temperature falls far below any temperature experienced on the earth. The absence of an atmosphere, and especially of water-vapour, leaves the surface of the moon exposed to these great variations of temperature, and it is to this cause that any changes, if such should be found, in the moon's surface are to be attributed; for without water or air there can neither be storms of wind nor floods to modify the surface.

The moon has been carefully mapped, and names have been given to all the more prominent features. The term *Mare* (Lat. sea) has been applied to the large dark plains, an example of which is the *Mare Crisum*, easily seen as an oval dark spot near the edge of the new moon. Another example is the *Mare Serenitatis*, the large dark oval near the right of the accompanying illustration. The terms *Palus* (marsh), *Lacus* (lake), and *Sinus* (bay) have all been fancifully used to denote smaller dark areas.

The most striking feature is furnished by the *craters*. Under this term are included more or less circular areas of diameters from 150 miles to less than a mile, surrounded by walls which may reach as much as 18,000 feet in height. Often a small peak is found in the centre. It will be seen from the

illustration how thickly the surface of the moon is covered with craters. The larger craters are named after astronomers and philosophers—e.g. Copernicus, Tycho, Plato. Besides these there are the ranges of mountains called the Alps, Apennines, Cordilleras, &c., similar to terrestrial chains. The heights of many of the lunar mountains have been measured. Galileo showed how this could be readily done by the lengths of their shadows. The highest peak, *Newton*, has an altitude of 24,000 feet. The lunar *ridges* (so named by Schröter, their discoverer in 1787) are clefts or cracks in the surface, passing often through mountains and valleys, sometimes for a distance of 300 miles, their breadth being relatively so small as to give them the appearance of true cracks. Some of the most striking of all lunar appearances are the broad white *rays* which diverge from a few central points. Those from the crater *Tycho* extend to great distances, in one case to nearly 2000 miles. Their breadth is from ten to twenty miles, and they pass over mountains and plains.

The mapping of the moon is a branch of astronomy known as *Selenography*. The first complete map was made by Hevelius. In 1836 Beer and Mädler published a very careful description of the moon with accompanying maps, the results of many years' study and micrometric measurement. Recently Franz and Saunder, from measurements of photographs, have largely increased the accuracy with which the positions of various points on the moon are known.

The first photograph of the moon was a daguerreotype taken by Draper in 1840. Since the invention of the dry-plate process it has become a comparatively easy matter to obtain fairly good photographs of the moon. Only a short exposure of at most a few seconds is needed. But as in one second of time the moon moves $\frac{1}{2}''$, it is necessary, if very sharp photographs are to be obtained, to give special movements to the telescope, so that its motion may exactly correspond with that of the moon in the sky. Owing to slight atmospheric changes, the best results are only obtained occasionally, and as the outcome of many trials. Excellent photographs have been taken at the Lick Observatory, but the most extensive series has been obtained at Paris by MM. Loewy and Puiseux, who have published beautiful enlarged photographs. Even finer photographs, though few in number, have been obtained by Mr Ritchey, using a colour-screen with the refractor of the Yerkes Observatory. Probably the finest photographs are those taken with the large 100-inch reflector of the Mount Wilson Observatory.

The etymology of the word *moon* is interesting, but not in all respects certain. The long-prevalent view that our word and its numerous cognates are derived from a root *mē-*, to measure, from its function as a measure of time, is attractive and plausible, but cannot be substantiated. More likely, according to the *New English Dictionary*, our *moon*, with the cognate words in all branches of the Indo-Germanic family, has arisen, by substitution of suffix (Brugmann's view), from the *t*-stem *mēnoth*, month. Outside the Teutonic group of names for the moon (O. E. *mōna*, Old Frisian *mōna*, Old Saxon *māno*, Old High German *māno*), compare Greek *mēnē*; and with reduced grade of the stem suffix *mens-*, Sanskrit *mās*, *māsa*, Zend *manha*, Greek *mēn* for *month*, Ionic *meis*, Latin *mensis*, Irish *mí*.

Harvest-moon.—At or about the time of harvest in the north temperate zone the sun in its annual course is approaching the celestial equator, which it crosses from north to south on September 22. On that date it sets close to the exact western point of the horizon. If it happens to be then also full moon, the moon rises that evening as the sun

sets, and is at its rising opposite the sun, or close to the exact eastern point of the horizon. Thus it begins to give light at sunset, and continues to do so until sunrise, when it sets opposite to the sun, just as the latter rises. This arrangement holds good without any great change for several days, so that there is practically no darkness, especially if the weather be fine. The full moon which thus illumines the autumn nights is called the *harvest-moon*. No other full moon in the year rises for so many days in succession so soon after sunset. If the date of full moon be not exactly September 22, still the same phenomena occur, though not with the same perfection, and the longer the interval between full moon and that date the less perfect they are. This is because the full moon, being on September 22, coincides with the time when the moon (being at full moon necessarily *opposite* the sun) is crossing the celestial equator from south to north, at which time its northward motion is most rapid. The position of any body on the celestial sphere determines the time of its rising at any place in our latitudes, and, if that position be altered, the time of rising will be altered also. If it moves *southward* the moon will tend to rise *later*, if it moves *northward* it will tend to rise *earlier*. We have seen that the moon's northward motion is most rapid when crossing the equator. Hence it has then a strong tendency to rise earlier each evening. But its motion towards the east (or *downwards*, when it is on the eastern horizon) gives it a tendency to rise later. These opposite tendencies, in the case of the September full moon, approach a balance, if the observer be in the latitude of northern Europe. Therefore the moon in that case rises only a few minutes later each evening for about a week. Farther north, about lat. $64\frac{1}{2}^{\circ}$, a balance is attained, and for two evenings the moon rises at the same time. Still farther north it rises *earlier* the second evening. But the most generally observed phenomena are of course those to be seen between latitudes 40° and 60° , which consist in the nearly full moon rising but little after sunset for several days in succession. In these latitudes of the southern hemisphere March enjoys the benefit of the harvest-moon, as September does in the north. And as celestial appearances are reversed to observers in different hemispheres, it follows that, when we have most benefit from the full moon, our neighbours at the antipodes have least.

For the lunar theory, see Airy's *Gravitation*; Herschel's *Outlines of Astronomy*; and E. W. Brown, *The Motion of the Moon* (1906). For selenography, Loewy and Puiseux, *Atlas Photographique de la Lune* (1896-1908); W. H. Pickering, *The Moon from Photographs* (1904); G. P. Serviss, *The Moon* (1908). On the formation of the craters, &c., from the point of view of a geologist, see Shaler, *Smithsonian Contributions to Knowledge*, vol. xxxiv. (1903).

Superstitions regarding the Moon.—The moon was anciently an object of worship, and even in the 17th century she was supposed by the common people of England to exercise great influence over human affairs. The times for killing animals for food, gathering herbs, cutting down wood for fuel, sowing seeds of various kinds, were all regulated by the 'age' of the moon, and these set periods were considered to be a necessary part of practical knowledge, and ignorance or neglect of them to be infallibly productive of loss. There were similarly defined periods for taking particular medicines and attempting the cure of particular diseases. Many such superstitions prevailed till a recent period in the Highlands of Scotland, favourable or unfavourable consequences from any occurrence being predicted according to the age of the moon at the time it happened. Through-

out Scotland the waning moon was considered to have an evil influence, and full or new moon to be the most auspicious season for commencing any enterprise. The same opinion was held in Scandinavia and Germany, and the history of all nations teems with similar superstitions. The special influence of the moon on persons of weak or wavering reason is preserved in our words *lunatic* and *moon-struck*, and is still an article of popular belief. Amongst mere superstitions must be ranked the old and widespread belief that the changes of the moon influence the weather on the earth, bringing about fair or rainy, settled or stormy weather; so that from the moon's periods predictions as to the weather may be made. The only known weather influence is a slight but appreciable tendency to dispersion of clouds shortly after full moon. See the article ECLIPSES.

In the Edda we read that 'Mundilföri had two children—a son, Máni ('moon'), and a daughter, Sól ('sun');' and in German the moon is masculine and the sun feminine to this day. It was the same in Anglo-Saxon, although modern English has in this matter followed the classic mythology, in which Phœbus and Sol are gods and Selene, Luna, and Diana are goddesses; Grimm (*Deutsche Mythologie*, p. 666) quotes an old invocation to the 'New Moon, gracious lord' (Neuer Mon, Holder Herr), for increase of wealth; and down to recent times the German people were fond of speaking of 'Frau Sonne' and 'Herr Mond' ('lady sun' and 'lord moon'). The same inversion (as it appears to us) of gender is found among the Lithuanians and Arabians, and even the ancient Mexican *Meztle* ('moon') was masculine. Among the Slavs, according to Grimm, the moon is masculine, a star feminine, and the sun neuter. See the Rev. T. Harley's *Moon-lore* (1886; with bibliography).

Moon, MOUNTAINS OF THE, have played a mysterious part in African geography since the days of Ptolemy, who indicated them as containing the sources of the Nile. They were generally figured on mediæval maps as a high range crossing the entire continent from Abyssinia to the Gulf of Guinea. With them have been identified the mountains of Abyssinia, the groups of Kenya and Kilima-Njaro, and also Ruwenzori.

Moon, WILLIAM. See BLIND.

Moonseed. See MENISPERMACEÆ.

Moonstone. See FELSPAR.

Moonwort (*Botrychium Lunaria*), an interesting fern, native of Britain, and widely distributed over northern Europe, penetrating to within the Arctic regions and Asia, and along with the few other species of which the family is composed appearing also in North America. The plant is of simple structure, consisting of a root-stock bearing a single erect stem from 3 to 6 inches high. A single pinnate leaf springs from the stem about midway from root to apex, the thick, pale-green segments being half-moon shaped. The fructification is developed on a branched spike from 1 to 2 inches long. *B. virginianum*, the Rattlesnake Fern, is the largest growing species.

Moor. See ECOLOGY, BOG, PEAT, WASTE LANDS; and for Grouse Moors and Moorfowl, see GROUSE.

Moore, ALBERT JOSEPH (1841-93), painter, son of William Moore, portraitist, was noted for his diaphanous draperies in figure-subjects.

Moore, GEORGE, born in 1857, the son of a Mayo landowner and M.P. associated with the Young Ireland party, was educated at Oscott, and published poems in 1878 and a tragedy on Martin Luther in 1879. For some years he studied in Paris. *A Mummer's Wife* (1884) showed Zola's influence;

Vain Fortune (1891) and *Esther Waters* (1894; reshaped 1920) are in a similar vein of 'realism.' *Evelyn Innes* (1898) had a sequel in *Sister Teresa*. As an exponent of the Celtic revival he proclaimed English literature dead or dying, and, mainly on Celtic-national grounds, renounced the Roman Catholic faith. *Confessions of a Young Man* (1905) began an autobiographical series continued in *Memoirs of my Dead Life* (1906) and *Hail and Farewell, a Trilogy* (1911-14). Later works are *The Brook Kerith* (on the story of Christ, 1916), *A Storyteller's Holiday* (1916), *Héloïse and Abelard* (historical novel, 1921), *The Coming of Gabrielle* (1921), and *In Single Strictness* (1922). See books by Maclean (1906), Mitchell (1916), and the *Life*, by his brother, of their father (1913).

Moore, JOHN (1729-1802), born at Stirling, a minister's son, studied medicine at Glasgow, and there began to practise. As medical attendant to the young Duke of Hamilton he travelled six years on the Continent, and on his return (1778) settled in London. His *View of Society and Manners in France, Switzerland, Germany, and Italy* (4 vols. 1779-81) was well received; but the novel *Zeluco* (1789), which suggested Byron's *Childe Harold*, is to-day the least forgotten of his works.

Moore, SIR JOHN, the hero of Coruña, born at Glasgow, 13th November 1761, was eldest son of the preceding. He entered the army as ensign when only fifteen, and first distinguished himself in the descent upon Corsica (1794); he served in the West Indies (1796), in Ireland during the rebellion of 1798, and in Holland in 1799. He was in Egypt in 1801 with the army under Abercromby, and obtained the Order of the Bath for his services in command of the reserve. When war again broke out in 1802 Moore served in Sicily and Sweden. In 1808 he was sent with a corps of 10,000 men to strengthen the English army in the Peninsula. He arrived in Mondego Bay, August 19, and assumed the chief command on the return to England of Sir H. Burrard. In October he received instructions to co-operate with the forces of Spain in the expulsion of the French from the Peninsula. He moved his army from Lisbon with the intention of advancing by Valladolid to unite himself with the Spanish general Romana, and threaten the communications between Madrid and France. But the apathy of the Spaniards, the successes of the French in various parts of the Peninsula, and, above all, the folly and intrigues of his own countrymen, soon placed him in a critical position. Yet he had determined to make a bold advance from Salamanca to attack Soult when the news reached him that Madrid had fallen, and that Napoleon was marching to crush him at the head of 70,000 men. Moore's forces amounted to only 25,000 men, and he was consequently forced to retreat. In December he began a disastrous march from Astorga to Coruña, a route of near 250 miles, through a desolate and mountainous country, made almost impassable by snow and rain, and harassed by the enemy. The soldiers suffered intolerable hardships, and arrived at Coruña in a very distressed state. It was impossible to embark without fighting, and Soult was in readiness to attack as soon as the troops should begin to embark. The battle was mainly one of infantry, for the cavalry after destroying their horses had gone on board, and the bulk of the artillery, for which the ground was not adapted, had also been withdrawn. On the 16th January 1809 the French came on in four strong columns. A desperate battle ensued. While animating the 42d Regiment in a brilliant charge in an early stage of the action, Moore was struck by a cannon-ball on the left shoulder and

died in the moment of victory. The French were defeated with the loss of 2000 men; and the dead leader was buried just before the embarkation of his troops—at eight in the morning apparently, and not at night, spite of Wolfe's famous poem. The British army in this expedition lost their magazines and 6000 soldiers. Soult raised a monument to Moore's memory on the field of battle, and another was erected in St Paul's Cathedral. His uncommon capacity was mated with disinterested patriotism and heroic ascendancy of character.

See the (too fraternal) *Life* by his brother (2 vols. 1834); his *Diary*, edited by General Maurice (who says Moore delivered 'the boldest, the most brilliant, and the most successful stroke of war of all time'; 1904); and Oman's edition of Napier's *Peninsular War* (1904; in which Moore's mistakes are insisted on).

MOORE, THOMAS, the 'Bard of Erin,' was born at 12 Angier Street, Dublin, on 28th May 1779, the son of a Catholic grocer. From the school where Sheridan had been educated, and where he himself became a 'determined rhymist,' he passed in 1794 to Trinity College, and thence, after taking his B.A., proceeded in 1799 to London to keep terms at the Middle Temple. He brought with him a translation of Anacreon, which came out in 1800, dedicated to the Prince of Wales, his patron then, but the butt from 1813 of his satire. It proved a great hit, and, with his musical talent, procured him admission to the best society. In 1801 followed the *Poetical Works of the late Thomas Little*, whose pretty erotics were a good deal blamed, and very widely read. In 1803, through Lord Moira's influence, he was appointed registrar of the Admiralty court at Bermuda. He went there to arrange for a deputy, and, after a tour in the States and in Canada, returned in a twelve-month to England—the democratic notions of his Dublin days toned down by his transatlantic experience. For his *Odes and Epistles* (1806) he was sharply taken to task in the *Edinburgh*. The bulletless duel with Jeffrey was the consequence, over which Byron made so merry, but which left the non-combatants fast friends for life. In 1811 he married an actress, good Bessy Dyke (1793–1865), and, after living successively in Leicestershire, in Derbyshire, and at Hornsey near London, in 1817 they settled at Sloperton Cottage, near Bowood, Lord Lansdowne's seat, in Wiltshire.

Meanwhile, among other fugitive pieces, Moore had published the earlier of the *Irish Melodies* (ten parts, 1807–34) and *The Twopenny Post-bag* (1812), whose tropes at once glittered and stung. Now he became anxious to emulate his brother-poets, who published in quartos. He fixed on an oriental subject, and in 1817 the long-expected *Lalla Rookh* appeared, dazzling as a firefly; and the whole English world applauded. After the publication he went with Rogers to Paris, and there wrote *The Fudge Family* (1818). For *Lalla Rookh* the Longmans paid him 3000 guineas; the *Irish Melodies* brought in £500 a year; but Moore had 'a generous contempt for money,' and about this time his Bermuda deputy embezzled £6000. Moore's liability was reduced by compromise to £1000, which he ultimately paid by his pen; but in 1819, to avoid arrest, he went to Italy with Lord John Russell. He spent five days at Venice with Byron (his friend since 1811), went on with Chantrey to Rome, and then with his family fixed his abode in Paris, where he wrote *The Loves of the Angels* (1823) and a prose romance, *The Epicurean* (1827). He returned in 1822 to Sloperton; and here, except for occasional 'junktetings' to London, Scotland, and elsewhere, he passed his last thirty years. To those years belong the *Memoirs of Captain Rock* (1824), the *History of Ireland* (1827), and the *Lives of Sheridan* (1825), Byron (q.v., 1830), and Lord Edward

Fitzgerald (1831). In 1835 he received a pension of £300, but his last days were clouded by sorrow and suffering—the loss of his two sons, and the decay of his mental faculties. 'I am sinking,' he writes to Rogers in 1847, 'into a mere vegetable.' He died on 25th February 1852, and was buried in Bromham Churchyard.

Moore in his lifetime was popular as only Byron; Earl Russell called him 'greatest of English lyrists,' and Kit North ranked him above Burns; but to-day he is placed amongst writers marred by artificiality and 'sensibility.' Even in his lyrics there is a tedious sameness, with their eternal 'love of one's country, of the wine of other countries, and of the women of all countries.'

See his *Memoirs, Journal, and Correspondence*, 'edited' by Lord John (afterwards Earl) Russell (8 vols. 1852–56); Vallat's French monograph (1886); Litton Falkiner's selections (with Essay, 1904); Godley's edition (1910); and Stephen Gwynn's *Moore* (in 'Men of Letters,' 1905).

MOORE, THOMAS STURGE, author, poet, art critic, and wood-engraver, was born in Sussex in 1870. His first published work was a miscellany, *The Vine-dresser and Other Poems* (1899). *Pan's Prophecy*, which appeared in 1904, is perhaps his masterpiece of imagery. Of his other works may be mentioned *The Little School* (1905; enlarged ed. 1917); *The Powers of the Air* (1920); two poems, *Danaë* and *Aforetime* of the same year; and some essays and studies on Dürer, Correggio, and others. He designed some wood-engravings for the poems of Yeats.

Moor Park. See FARNHAM.

MOORS, a vague ethnographical expression applied to people whose geographical frontiers have been constantly shifting. First given (Mauri) to the inhabitants of the kingdom and subsequent Roman province of Mauretania, comprising within variable limits the whole country west of Numidia, now called Algeria and Morocco, later on it included the inhabitants of the whole of Africa north of the Sahara and Atlas from Tripoli westwards. Here for some three centuries flourished the great African church of Tertullian, Cyprian, and Augustine; in 429 the country was overrun by the Arian Vandals from Spain, but was recovered for the Byzantine emperors by Belisarius (533–36); invaded by the Arabs in 647, it was speedily subdued, and the Moors embraced Mohammedanism as quickly as they had embraced Christianity, and have clung to it ever since. From 1830 these countries have been gradually occupied and colonised by the French, with the exception of Italian and Spanish protectorates. The Arab slave-dealers and mixed Arab and Negro clans to the south are sometimes called the *Moors* of the western Sudan. Whether in Algeria or in Morocco the Moors cannot be considered as a pure race. Some authorities take them as nearly equivalent to the Berbers, even the nomad tribes; others restrict the name to an admixture of Arab blood, and call Moors only the more settled Arabic-speaking population of the town.

In European history the term is applied in a special sense to the Arab and Berber conquerors and occupants of Spain from 711 to 1492. Within twenty years from their first landing these tribes had overrun the whole of Spain except the Asturias, had got possession of the Narbonnaise (719), had raided into France, till finally repulsed by Charles Martel near Tours in 732. For a short time one khalif ruled the whole of Islam from beyond Bagdad to the Atlantic. When in 750 the Abbaside khalifs overthrew the Omniades a descendant of the latter, Abdurrahman I., escaped and founded the khalifate of the West at Córdoba in 755. His dynasty lasted

till the degradation of Hashim III. in 1031. Then after a period of anarchy the Almoravides (Berbers) succeeded from 1086 to 1147; the Almohades followed from 1130 to 1232. The greater part of Spain had now been lost, but the Beni-Nasr held Granada from 1232 to 1492. The chief steps of the Spanish re-conquest are the taking of Toledo, 1085; Saragossa, 1118; Valencia, by Jaime I. of Aragon, 1238; Seville, 1248; Murcia, 1260; Granada, 1492. The first of these invaders of Spain were mainly of Arab blood, and brought with them capacities of civilisation. From the 8th to the close of the 11th centuries the Spanish Moors in architecture, literature, science, industry, manufacture, and agriculture were far in advance of any northern European race of that date; no other people in western Europe could have then built a cathedral like the mosque of Córdoba (784-793); in philosophy and in the terms of mathematical and astronomical science they have left their impress on most of the languages of western Europe. Their toleration of the Christians, though contemptuous, contrasts favourably with that of the Christians towards the Moors after the conquest. But after the 12th and 13th centuries the conditions were reversed. The Moors had no reserve of civilisation or of increasing resources to fall back upon in northern Africa; they were degenerating, while behind Christian Spain was a Europe ever growing more civilised and richer in resources of every kind. The conquest was retarded by the division and intestine struggles of the Christian kingdoms; but these same causes told far more fatally on the Moors. There were never more than five or six separate Christian kingdoms; but the Moorish states were at times divided among over twenty little kings, and every dynasty in succession fell to pieces through intestine strife. The advance of the Turks westward after the taking of Constantinople (1453) was too late to help their co-religionists in Spain. Khair-ed-din Barbarossa (q.v.) established himself in Barbary in 1518, and was more or less successful in a plunderous warfare against Spain; but after the naval defeat of Lepanto (q.v.) in 1571, however much the Moors might harass Spain, there was no real danger of a re-conquest. Their piratical efforts only served to raise a hatred between two chivalrous races who had once respected each other and to carry it to the bitterest fanaticism.

For the expulsion of the Moors after the fall of Granada in 1492 and the treatment of those who remained in subjection, see FERDINAND, SPAIN, MORISCOS. See also KHALIFS, ALMORAVIDES, ALMOHADES, ALGERIA, ANDALUSIA, ARABIAN ARCHITECTURE, CÓRDOBA, GRANADA, MOROCCO, TUNIS; works by P. de Gayangos (1840), R. P. A. Dozy (1861-81), Stanley Lane-Poole (1887), and S. P. Scott (3 vols. 1904).

Moorshedabad. See MURSHIDABAD.

Mooruk. See CASSOWARY.

Moose. See ELK.

Moose Jaw, a city of Saskatchewan, at the confluence of Moose Jaw River and Thunder Creek, 400 miles W. of Winnipeg, on the Canadian Pacific Railway, an important junction for branch and connecting lines. It is the centre of a fine agricultural country. Pop. 19,000.

Moot, Moot-hill. See FOLKMOOT.

Moplas, a race of southern India, mainly near the Malabar coast, who as fanatical Mohammedans have caused trouble by outbreaks. Descended from the old Arab traders, they number over 1,000,000.

Moquis. See PUEBLOS.

Moraceæ, a family of dicotyledons, akin to the elms and nettles, mostly tropical and subtropical trees and shrubs, with latex, and opposite leaves which shed their stipules. The unisexual flowers,

with parts mostly in fours, aggregated in a globular or disc-shaped inflorescence, commonly give rise to a multiple fruit, of which the Bread-fruit (q.v.), Mulberry (q.v.), and Fig (q.v.) are well-known examples. The latex of *Ficus* and *Castilloa* yields India-rubber (q.v.); that of *Galactodendron* (see COW-TREE) is a milk-substitute. See also CECROPIA, CONTRAYERVA, HEMP, HOP, UPAS.

Moradabad, capital of a district of British India, on the Ramganga, 100 miles E. by N. of Delhi, is noted for its metal-work and trade in country produce; pop. 82,600.

Moraine. The masses of rock which, by atmospheric action, are separated from the mountains bounding the valleys along which glaciers flow, find a temporary resting-place on the surface of the ice, at the margin of the glacier, and are carried along with it, but so slowly that they form a continuous line along each margin. These lines of debris are called *lateral moraines*. When two glaciers unite, the two inner moraines unite also and form one large trail in the middle of the trunk glacier, and this is called a *medial moraine*. A large portion of these rocky fragments at length reach the end of the glacier, and here the melting ice leaves it as a huge mound, which is known as a *terminal moraine*. The rock-debris, sand, clay, gravel, &c., which are dragged forward underneath the ice, are called *ground-moraines*, or *moraines profondes*. See GLACIER, BOULDER-CLAY.

Moralities. See MYSTERIES.

Moral Philosophy. See ETHICS.

Morar, a district and loch in the west of Inverness-shire, south of Loch Nevis. The loch, 12 miles long, is by far the deepest in the British Isles, its maximum depth being 1017 feet.—MORAR is also the British cantonment near Gwalior.

Morat (Ger. *Murten*), a small town in the Swiss canton of Freiburg, 12 miles ESE. of Neuchâtel, lies on the Lake of Morat ($\frac{3}{4}$ by 2 miles, 1428 feet above sea-level). Here, on 22d June 1476, the Swiss gained a victory over Charles the Bold, Duke of Burgundy.

Morata, OLYMPIA, a 16th-century scholar, was born at Ferrara in 1526, the daughter of the poet Fulvio Pellegrino Morato (who died in 1547). Already in her sixteenth year she gave public lectures in her native city; but, having in 1548 married the German physician Andreas Grundler, she followed him to Germany and became a Protestant. Driven from place to place by the religious wars, and reduced to penury, she died at Heidelberg, 20th October 1555, leaving numerous Latin and Greek poems, mainly on religious subjects (edited 1558, 1870, &c.), a treatise on Cicero, dialogues, letters, &c. See the Monograph by Bonnet (4th ed. Paris, 1865).

Moratin, LEANDRO FERNÁNDEZ DE, comic poet, was born at Madrid, 10th March 1760, and was the son of a poet. In 1790 appeared his first and best comedy, *El Viejo y la Niña*; it was followed by *La Comedia nueva*, *El Barón*, *La Mogigata*, and *El St de las Niñas*. Godoy conferred several ecclesiastical benefices upon him; Joseph Bonaparte made him chief royal librarian; but after 1814 he took refuge in Paris. He died in Paris, 21st June 1828.

Morava. See MARCH (river).

Moravia (Ger. *Mähren*), till 1918 a crown-land of the Austrian empire, now the middle section of the Czechoslovak republic, is bounded NE. by Silesia, E. by Slovakia, S. by Lower Austria, and NW. by Bohemia. It is enclosed on all sides by mountains, being separated from Silesia by the Sudetes, from Bohemia by the Moravian chain, and from Slovakia by the Carpa-

thian Mountains; while branches of these various chains intersect the whole country except in the south, where there are extensive plains rising to about 800 feet. Numerous small rivers flow south-east, and fall into the March or Morava, from which the country derives its name, and which joins the Danube. The Oder rises among the mountains on the north-east, and soon leaves the country. Moravia is essentially an agricultural region. On the whole the soil is rich. The principal crops are rye and oats; then come barley, wheat, potatoes, beet-root, leguminous plants, and many fruits and vegetables. The breeding of animals is actively prosecuted. The principal mineral products are coal and iron, with some graphite. The principal branches of industry are the manufacture of woollen, linen, and cotton goods, and beet-sugar. Brünn (q.v.), or Brno, the capital, is the chief emporium for the manufactures. A university was set up at Brünn in 1919. Of 2,662,884 inhabitants (in 1921), over two millions were Czechs, over half a million Germans. For history, see CZECHOSLOVAKIA.

Moravia, a Latin name for the province of Moray (q.v.).

Moravians, otherwise known as Herrnhuters, The Church of the Brethren, or The Unity of the Brethren, are a small body of Protestants who claim to be the modern representatives of the ancient church of the Bohemian Brethren (see **BOHEMIA**), or *Unitas Fratrum*, which first took a definite shape in 1467, when the followers of Peter of Chelcizky, a pious layman and a contemporary of Huss, formed themselves into a separate ecclesiastical community on the apostolic model. They held that all Christians should lay aside distinctions of rank, abstain from military service and the use of oaths, and live in literal accordance with the teaching of Christ. These views forced them to keep aloof from both sections of the Hussites proper, and, though there may have been Waldenses amongst them, they owed very little at any period of their history to these crypto-Protestants. At the synod of 1467 three elders, a bishop, and two presbyters were chosen by lot, and received ordination probably from a Waldensian priest, though the first beginnings of the church are wrapped in a mist of confused traditions and miraculous tales. Under the influence of Lucas of Prague, a man of strong character and great literary talent, the Brethren in 1494 abandoned their levelling ideas, but maintained their stern and rigid discipline, and by the beginning of the 16th century there were between 300 and 400 churches in the Unity. They had much friendly intercourse with Luther, but stood out for the celibacy of the clergy, the doctrine of works, and congregational purism. For a time, however, the Unity was under the influence of Lutheran ideas, though the Brethren had naturally a much stronger sympathy with Calvinism. From the commencement of its history times of persecution alternated with times of repose, and many of the Brethren, especially in the early part of the 16th century, were forced to flee to Poland and Prussia. In 1570 the Polish branch united with the Reformed Church, and, though in 1600 the Bohemian and Moravian branches included two-thirds of the population and most of the nobility, the Brethren having got mixed up with the revolution which ended so disastrously in 1620, by 1627 the church was entirely broken up and destroyed. In 1722 some of the Moravian descendants of the suppressed Unity, who had been roused by the preaching of a carpenter, Christian David, a converted Roman Catholic, resolved to emigrate, and were allowed by the pious young Count Zinzendorf (1700-60) to

settle on a part of his property in Saxony, close to the Austrian frontier. The first company consisted of two brothers, their wives, four children, two relations, and David, but these were soon joined by other emigrants from Moravia and Bohemia, and by pious and fanatical people of various nationalities. Five years later the settlers at Herrnhut ('The Lord's Keeping') amounted to over three hundred. They at first attended the parish church, but soon began to quarrel among themselves and with the Lutheran pastor, and adopted wild and extravagant views. Owing to the exertions of Zinzendorf peace was restored, and the settlers formed themselves into a society in communion with the Lutheran Church, and drew up certain rules for their guidance in all matters of religion and conduct, the chief of these being that all in Herrnhut should live in love with all their brethren and with all the children of God in all religions.

Twelve elders were chosen to be the teachers and overseers of the community, and these came to be assisted afterwards by male and female 'labourers' of all sorts, including 'inspectors' of spiritual nuisances, and even of the work done and the goods sold by the Brethren. August 13th of this year (1727) is still celebrated as the spiritual birthday of the renewed church. By 1733 the Society had become a distinct church, and in 1735 the first bishop was elected and was ordained by Jablonski, court chaplain in Berlin, one of the two surviving guardians of the precious apostolical succession, which had been handed down by Amos Comenius, the last bishop of the old Unity. Although the Moravians imitated certain parts of the constitution and practice of the original church, much of what was peculiar in their views and discipline is to be traced to Zinzendorf, who was consecrated bishop in 1737, and was their 'advocate' until his death in 1760. The members of the community were divided into 'bands,' which met to exchange experiences, to study the Bible, to sing and pray, and there was a special division, still maintained, into 'choirs,' which consisted respectively of unmarried men, unmarried women, married couples, widowers, widows, boys and girls. Some of the 'choirs' had their own houses, where the members lived under the direction of a brother or sister. There were two daily services in which all joined, and hourly prayer was kept up night and day by certain members of the bands, while every morning the Brethren were supplied with a text as a 'watchword.' Love-feasts were introduced by Zinzendorf, and are still held, though the practice of feet-washing before the communion has been abandoned. All important matters, even marriage, were decided by an appeal to the 'lot,' and, as Zinzendorf taught that death was a joyous journey home, the departure of a brother or sister was announced by blowing a trumpet, each 'choir' having its own peculiar air.

Various branch settlements were established in Germany, America, and Britain, and in these the Herrnhut arrangements were strictly carried out; but, when this was not possible, congregations were set up, or societies were created, composed of members of other Protestant churches, as Brethren might belong to either of the three 'tropes'—the Lutheran, the Reformed, or the Moravian. Some of the Moravians came into contact with the Wesleys and Whitefield, and had considerable influence on their views, and they were even patronised by Anglican dignitaries, but partly owing to misrepresentation and partly owing to injudicious conduct on the part of some of the Brethren, their use of certain foolish hymns and sensuous and grotesque language in reference to the wounds of Christ, bitter opposition was roused against them both in England and the Continent.

Since the middle of the 18th century the home-history of the Unity has been uneventful.

At present the executive government of the church is vested in the Elders' Conference of the Unity, a clerical body composed partly of bishops and partly of presbyters. This conference carries out the injunctions of the synod, the supreme court of the church, which meets every ten years at Herrnhut. At the meeting in 1889 a synodal resolution was passed practically abolishing the determining of questions by lot. There are also provincial synods and conferences, and each congregation is governed by its own Elders' Conference, which consists of all the male and female 'labourers.' The bishops enjoy no special privileges in the way of rank or salary, but have the sole power of ordaining. The ordinary church service is largely liturgical, and hymn-singing has always been a prominent feature of Moravian worship. The Moravians have no formal confession, though at an early period they declared their adhesion to the Augsburg Confession, and the litany which is used on Easter Sunday and two other Sundays is really a creed. The Unity is now divided into four provinces: the British, German, and north and south American. The Moravian Church is *par excellence* the missionary church of Christendom. The mission to the West Indian slaves was started in 1732, and soon that to Greenland (q.v.)—the latter made over in 1900 to the Danish Lutheran Church.

See histories of the Brethren by Holmes (1828), Bost, Schweinitz, Gindely, Goll, Cröger, Hamilton, and Hutton (1909); on their constitution, works by Seifferth (1866); on their missions, by Thompson (1883), Hamilton (1901), and Hutton (1923); besides the Lives of Zinzendorf (q.v.).

Moravides. See ALMORAVIDES.

Moray, PROVINCE OF, an old territorial division of Scotland, comprising the modern counties of Moray (or Elgin) and Nairn, eastern Inverness, and part of Banff. The two first-named form (since 1918) the parliamentary county of Moray and Nairn. The 'laich,' or lowlands, noted for its fertility, was subject to constant raids from the neighbouring highlands.

Moray, JAMES STUART, EARL OF, by Protestants called the 'Good Regent,' was the natural son of James V. of Scotland, by Margaret, daughter of John, fourth Lord Erskine, whom James in 1536 thought seriously of marrying, even though she had already wedded Sir Robert Douglas of Lochleven. Born in the year 1531, in 1538 he was made prior in commendam of St Andrews, in 1556 joined the Reformers, and almost immediately became the head of the Protestant party in Scotland. In 1561 he was despatched to France to invite his half-sister, Queen Mary, to return to her kingdom; and on her arrival he acted as her prime-minister and chief adviser. In 1562 she created him Earl of Mar; but that earldom being claimed by Lord Erskine, the title of Earl of Moray was conferred instead on Lord James, who put down the Border banditti and defeated Huntly at Corrichie. Strongly opposed as he certainly was to the marriage of Mary to Darnley (1565), he is falsely alleged before it to have endeavoured to seize the pair near Lochleven; and after it he openly appealed to arms, but was easily put to flight by the queen, and forced to take refuge in England. He did not return to Edinburgh till 10th March 1566, the day after Rizzio's murder, to which he was certainly privy. In April 1567 he withdrew to France, but in the following August was recalled by the nobles in arms against Mary, and found her a prisoner at Lochleven, and himself appointed regent of the kingdom. In his famous interview with the queen on the 15th he 'behaved himself rather like a ghostly father unto her than like a

counsellor.' On Mary's escape he defeated her forces at Langside, near Glasgow (13th May 1568), and afterwards was one of the commissioners sent to England to conduct the negotiations against her. He then, as always, acted with extreme wariness; and after his return to Scotland by his vigour and prudence he succeeded in securing the peace of the realm, and settling the affairs of the church. But on 23d January 1570 he was shot at Linlithgow by James Hamilton of Bothwellhaugh, who was instigated thereto by Mary's adherents, and prompted also, it may be, by personal enmity. He was buried in St Giles's, Edinburgh. Of his ambition there can hardly be question; still, the most different estimates have been formed of his character, according to men's estimates of Mary. See MARY, QUEEN OF SCOTS, and works there cited.

Moray, SIR THOMAS RANDOLPH, EARL OF, nephew and, from 1308, comrade of Robert Bruce, recaptured Edinburgh Castle from the English (1314), commanded a division at Bannockburn, took Berwick (1318), won the victory of Mitton (1319), invaded England again in 1320 and 1327, and was regent from Bruce's death to his own at Musselburgh, 20th July 1332.

Moray Firth, an indentation of the German Ocean, on the north-east coast of Scotland, between Kinnaird's Head in Aberdeenshire and Duncansbay Head in Caithness.

Morayshire. See ELGINSHIRE.

Morbihan, a maritime department of France, formed out of ancient Brittany, with the Atlantic on the south and Finistère on the west. Area, 2624 sq. m.; pop. (1872) 490,352; (1921) 546,047. The coast is much indented, and has a multitude of bays, promontories, harbours, and islands. The largest island is Belle Isle (q.v.). The department forms a plateau of no great elevation, partly cultivated, partly occupied by extensive tracts of heath and marsh (see BRITANNY). Morbihan is divided into the four arrondissements of Vannes, Lorient, Ploermel, and Pontivy. The chief town is Vannes (q.v.), but the most populous is Lorient (q.v.). Many ancient customs still prevail in Morbihan; communal proprietorship survives there, and in some of the islands the *curé*, assisted by a council of notables, governs the people in a patriarchal fashion.

Mordants. See DYEING.

Mordaunt, CHARLES. See PETERBOROUGH.

Mordvins, a Finnic race, now however greatly intermingled with the Russians, who dwell along the middle course of the Volga, from the government of Nijni-Novgorod to that of Samara. They number about a million.

More, HANNAH, was the fourth daughter of the village schoolmaster of Stapleton, near Bristol, where she was born in 1745. As a child she showed great quickness of apprehension and a good memory. Her sisters were sent to a school in Bristol, and when the eldest was twenty-one they opened a boarding-school there, to which Hannah went when she was twelve years old. She wrote verses at an early age, and in 1762 she published *The Search after Happiness*, a pastoral drama. In 1774 she went on a visit to London, and was introduced to the Garricks, and by them to Dr Johnson, Burke, Sir Joshua Reynolds, and the best literary society of London. During this period of her life she wrote two tales in verse, and two tragedies, *Percy* and *The Fatal Secret*, both of which were acted. While in London she went a great deal into society, but gradually found this mode of life to be unsatisfactory, and was led by her religious views to withdraw from it. After the publication of her *Sacred*

Dramas she retired to Cowslip Green, a cottage near Bristol, where she did much to improve the condition of the poor in her neighbourhood by establishing schools for their instruction. She still continued her literary work, and helped by her writings to raise the tone of English society. Her essays on *The Manners of the Great* and *The Religion of the Fashionable World*, a pamphlet on *Village Politics*, her novel *Cælebs in Search of a Wife*, and a tract called *The Shepherd of Salisbury Plain*, are some of the most popular of her works. In 1828 she moved from Barley Wood, a house she had built for herself near Cowslip Green, to Clifton, where she died, 7th September 1833. See books by Roberts (1834), Thompson (1838), Miss Yonge (1888), Miss Harland (1901), and Miss Meakin (1911); and her *Letters*, ed. Brimley Johnson (1925).

More, HENRY, one of the Cambridge Platonists, was born at Grantham in Lincolnshire in 1614. He was educated at Eton and Christ's College, Cambridge, revolted early against the Calvinism of his parents, and gave himself entirely to philosophy, especially to Plato and more particularly the Neoplatonist writers. He took his Bachelor's degree in 1635, his Master's in 1639, when he was elected fellow of his college. Here he remained all his life, nor could he be prevailed upon to accept church preferment. He lived in an atmosphere of unusual spiritual elevation, and exercised a great influence on the young men that gathered round him. Among his pupils was a young lady of family who became Viscountess Conway, and at whose seat of Ragley in Warwickshire More often stayed. This lady's sympathies with the mystic and the occult extended also to Van Helmont and Valentine Greatrakes, and the views of her circle told strongly on More, whose earlier rationality gradually gave place to fantastic mysticism and theosophy, so that his successive works decline in value. He died 1st September 1687, and was buried in the chapel of his college.

His *Divine Dialogues* (1668) are still of peculiar interest. His *Opera Theologica* were collected in 1675, his *Opera Philosophica* in 1678, his *Poems* in 1878. See the *Life* by Grosart Ward (1710; new ed. 1911), Tulloch's *Rational Theology*, and E. G. George's *Seventeenth Century Men of Latitude* (1908).

More, SIR THOMAS, was born in Milk Street, London, in 1478. His father, who subsequently became Sir John More, Justice of the King's Bench, was a man of character and talent, with a high sense of parental responsibility. More received his first instruction in Latin, then the basis of all education, in one of the most famous English schools of the time—that of St Anthony, Threadneedle Street, London. In after-life More wrote Latin with all the facility, though not with the classical purity, of the best Italian scholars of the Revival of Learning. When he attained his fifteenth year his father, after the fashion of the time, placed him as page in the household of Archbishop Morton, to whose virtues More afterwards paid the highest tribute in his *Utopia*. Morton, on his side, formed the highest expectations of More, and was in the habit of saying to the nobles who dined with him: 'This child here waiting at the table, whosoever shall live to see it, will prove a marvellous man.'

By Morton More was sent to Oxford, where the Renaissance was now represented by such men as Colet and Linacre, both of whom had travelled and studied in Italy. From Linacre he appears to have learned Greek, and from Colet he received a spiritual impulse which gave a direction to his entire life and opinions. From Colet More also learned those novel methods of biblical interpreta-

tion which Colet himself may have learned from Savonarola in Florence. By his acquaintance with the classics therefore, and by his enlightened views regarding the theology and the traditions of the church, More was emphatically a man of the new order. When, some time after leaving Oxford (probably about 1498), he first met Erasmus, both at once felt that they were in entire sympathy on all the deepest questions of the time.

It was his father's wish that he should follow the same profession as himself. Having completed his legal studies, first at New Inn and afterwards at Lincoln's Inn, he acted for three years as reader in Furnival's Inn. It marks the religious basis of More's character that he spent the next four years in the Charterhouse of London in 'devotion and prayer.' By his marriage with the eldest daughter of Mr Colte, a gentleman of Essex, he definitively made choice of a secular career. During the last years of Henry VII. he became under-sheriff of London and member of parliament, in which latter capacity he gave serious offence to the king by protesting against the excessive dowry demanded by Henry from parliament on the occasion of his daughter's marriage with James IV. of Scotland.

On the accession of Henry VIII. (1509) a brilliant prospect was opened up to More. It was Henry's ambition to surround himself with men of genius and accomplishments; and More had by this time attained a European reputation in the world of learning. As ambassador on two occasions to the Low Countries he had also given proofs of his tact and capacity for business. More, however, had little inclination for public life, and it was only after much hesitation that he took service under Henry. Introduced to the king through Wolsey, he rose rapidly in dignity and in the royal favour. He became Master of Requests (1514), Treasurer of the Exchequer (1521), and Chancellor of the Duchy of Lancaster (1525). For a time the king showed him every mark of personal attention—paying him unexpected visits at his house in Chelsea 'to be merry with him.' Congratulated on these marks of favour by his son-in-law Roper, More, who had divined Henry's real character from the first, replied: 'If my head would win him a castle in France it should not fail to go.' As speaker of the House of Commons (1523), More, on the occasion of Wolsey's demand for a subsidy of which the House disapproved, received the great cardinal in a manner that made him exclaim: 'Would to God you had been at Rome, Mr More, when I made you speaker.' More, however, still continued to enjoy Henry's favour; and on two occasions was sent on missions of importance to Francis I. and the Emperor Charles V.

On the fall of Wolsey in 1529, More, against his own strongest wish, was appointed to the office of Lord Chancellor. Seeing from the first where the king's divorce from Catharine of Aragon must eventually lead, he knew that only one fate could be in store for himself. In the discharge of his office he displayed a primitive virtue and simplicity, being 'ready to hear every man's cause, poor and rich, and keep no doors shut from them.' The one stain on his character as judge is the harshness of his sentences for religious opinions. In passing such sentences More acted only in the spirit of the time; but in his *Utopia* he had shown the clearest conception of the sacredness of the individual conscience. 'The Utopians,' he says, 'put the unbelievers to no punishment, because that they be persuaded that it is in no man's power to believe what he list.' More sympathised with Colet and Erasmus in their desire for a more rational theology and for radical reform in the manners of the clergy, but like them also he had no promptings to break with the historic church. He could look only with

displeasure, therefore, on the successive steps which led Henry to the final schism from Rome. In 1532 he resigned the chancellorship, and retired into private life. The disapproval of his policy by such a man as More could not be disregarded by Henry, and various attempts were made to win him over. Nothing, however, could shake the constancy of More, and his death became a mere matter of time and policy. The opportunity came in 1534. In that year Henry was declared head of the English Church; and More's steadfast refusal to recognise any other head of the church than the pope led to his sentence for high-treason after a harsh imprisonment of more than a year. The manner in which he met his death, while it is one of the commonplaces of English history, strangely illustrates an inveterate habit of his nature—the disposition to jest with the most serious questions and on the most momentous occasions. As, on 7th July 1535, he mounted the scaffold he exclaimed to a stander-by: 'Friend, help me up; when I come down again I can shift for myself; and raising his head after it had been laid on the block, he bade the executioner stay till he had put aside his beard, 'for,' said he, 'it never committed treason.'

More was twice married; but only by his first wife had he any family. In no life of More should his daughter Margaret, the wife of his biographer Roper, pass unmentioned. By her high character and accomplishments, but above all by her pious devotion to her father, she holds a place among the illustrious women of English history.

One of the distinguished characters in the political history of England, More also ranks high in the history of its literature. By his Latin *Utopia* (1516; Eng. trans. 1556) he takes his place with the most eminent humanists of the Renaissance, and he was the one literary Englishman of the 16th century well-known and admired on the Continent. In his *History of King Richard III.* (1513) he produced what may be regarded as the first book in classical English prose. In his personal character More was the most attractive and lovable of men; and his tragic end gave the crown to the moral beauty of his life. From Erasmus's sketch of him we realise all his virtues and all his attractions; but realise also that he was a winning rather than an imposing figure. He had ingenuity rather than insight; not infrequently his wit passed into levity and even into flippancy; and there was in his character a strain of morbidness and superstition which precluded him from the largest and humanest views of men and things. In 1886 he was beatified.

See Roper, *Life of Sir Thomas More* (first printed 1626); Lord Campbell, *Lives of the Chancellors*; Mackintosh, *Lardner's Cabinet Encyclopædia*; Seeborn, *Oxford Reformers*; D. Nisard, *Renaissance et Réforme*; editions of the *Utopia* by Lupton (1895), R. Steele (1923), and H. Girtein (1925); *Lives of More* by Father Bridgett (1891) and W. H. Hutton (1895); also works cited at HENRY VIII., WOLSEY, ERASMUS, and FISHER.

Morea, the mediæval and modern name for the Peloponnesus (q.v.). After being overrun by the Goths and Vandals, it became a prey, in the second half of the 8th century, to Slav invaders, who were gradually subdued and civilised by the Byzantine emperors. In 1205 the peninsula was conquered by the Normans, who formed its western portion into a feudal principality subject to the crown of Sicily. Michael VIII. Palæologus reconquered the country after 1261; but the principality of Achaia remained in the family of Villehardouin till 1346, when the male line became extinct. Various claimants now arose, and much strife and confusion ensued. At length, in 1461, the greater portion of the Morea fell into the hands of the Turks, the remainder being held by Venice, who abandoned it in 1540.

Venice reconquered the Morea in 1684, but again lost it to the Turks in 1714. For its later history, see GREECE.

Moreau, JEAN VICTOR, the greatest general of the French Republic, except Bonaparte, was born, 11th August 1761, at Morlaix, in Brittany, the son of an advocate, and was sent to study law at Rennes. On the outbreak of the Revolution he was chosen to command the volunteers from Rennes, served under Dumouriez in 1793, and displayed such military talent that in 1794 he was made a general of division; he took an active part in reducing Belgium and Holland under Pichegru in that and the following year. When Pichegru fell under suspicion, the Directory appointed Moreau, in the spring of 1796, to the chief command on the Rhine and Moselle. He crossed the Rhine at Kehl, defeated Latour at Rastatt and the Archduke Charles at Ettlingen, and drove the Austrians back to the Danube. But, owing to the defeat and retreat of Jourdan, he was obliged to make a desperate effort to regain the Rhine, which he accomplished, notwithstanding great difficulties, in a retreat that established his reputation for generalship more than all his previous victories. A suspicion of participation in the plots of Pichegru led to his being deprived of his command after the *coup d'état* of 18th Fructidor. In the following year (1798) he succeeded Schérer in the command of the army in Italy, which was hard pressed by the Russians and Austrians. By a retreat conducted with consummate skill, he saved the French army from destruction. The Directory, nevertheless, deprived him of the chief command, and gave it to Joubert. But Moreau remained with the army at Joubert's request to be present at the battle of Novi. Early in the engagement Joubert was killed and Moreau again assumed the command, and conducted the defeated troops to France. The noble disinterestedness of Moreau's character, his military talent, and his political moderation induced the party of Sieyès, which overthrew the Directory, to offer him the dictatorship of France; he declined it, but lent his assistance to Bonaparte on 18th Brumaire. Receiving the command of the army of the Rhine, Moreau gained victory after victory over the Austrians in the campaign of 1800, drove them back behind the Inn, and at last won the great and decisive battle of Hohenlinden (q.v.). A strong feeling of jealousy against Moreau now took firm root in Napoleon's mind. He accused his rival of participation in the plot of Cadoudal (q.v.) and Pichegru against his life, had him arrested, brought to trial, and found guilty on insufficient evidence, 9th June 1804. A sentence of two years' imprisonment was pronounced; Napoleon commuted it into banishment, and Moreau went to America, and settled in New Jersey. There he remained until 1813, when he accompanied the emperor of Russia and the king of Prussia in the march against Dresden. Fortunately for his fame he did not live to invade his country, for here, as he stood talking to the Emperor Alexander on 27th August, a French cannon-ball broke both his legs. Amputation was performed, but he died at Laun in Bohemia, 2d September 1813. He was buried in St Petersburg. See the studies by C. Jochmus (Berl. 1814) and A. de Beauchamp (trans. Lond. 1814).

Morecambe Bay, an inlet of the Irish Sea, separates the main portion of Lancashire from Furness. It is about 10 miles in average breadth and 18 miles in length, and receives the Leven, the Kent, and the Lune.—The watering-place of Morecambe, $3\frac{1}{2}$ miles WNW. of Lancaster, was incorporated as a borough in 1902; pop. 19,000 in holiday season.

Morel (*Morchella*) is a genus of Discomycete fungi, of which some species are eaten fresh and preserved in central and southern Europe.

Morelia, capital of the Mexican state of Michoacan, in a valley 6400 feet above sea-level, 130 miles WNW. of Mexico city, so named in honour of the patriot Morelos; pop. 40,000.

Morelli, GIOVANNI (1816-91), a notable art-critic, was born at Verona, and studied medicine in Germany. His works on the German and Italian painters applied new methods (the painting of hands, ears, &c. being specially regarded) to proving originals copies and copies originals.

Morepork. See PODARGUS.

Moreri, LOUIS (1643-80), was born in Provence, took orders, and was for five years a noted preacher at Lyons, where in 1674 he published *Le Grand Dictionnaire Historique, ou le Mélange Curieux de l'Histoire sacrée et profane* (in 1 vol. folio). In 1675 he went to Paris, and laboured at the expansion and improvement of this important work till his death.

Moresnet, a small Belgian territory 5 miles SW. of Aachen, was till 1919 partly Belgian, partly Prussian, partly neutral.

Moreton Bay, on the east coast of Queensland, Australia, is formed inside the islands of Moreton and Stradbroke, the former 20 miles and the latter 33 miles in length, and both about 5 miles in greatest breadth. The bay is 40 miles long by 17 broad; its southern half is dotted with islands and sandbanks. It receives the six considerable streams, Nerang, Pimpama, Logan, Brisbane, Pine, and Caboolture. The entrance at the north end is practicable at all times for vessels of the largest size; and the tortuous channel leading to the mouth of the Brisbane River has been improved (see BRISBANE). The southern entrances to the bay are practicable only for small sailing-boats.

Moreton-Bay Chestnut, a papilionaceous genus of which *Castanospermum australe* is the only species known. A native of Queensland, it belongs to the sub-order Papilionaceæ of the natural order Leguminosæ. The tree grows to the height of from 70 to 100 feet, with spreading branches clothed with pinnate leaves about a foot long. The flowers—bright yellow, and red—are succeeded by cylindrical pendulous pods of a bright brown colour, 6 to 8 inches long generally, containing about four seeds each, which are roundish but somewhat flattened on one side. Though likened to the sweet chestnut, they are much inferior in delicacy of flavour, being very astringent; but they are somewhat improved when roasted.

Morgagni, GIOVANNI BATTISTA (1682-1771), founder of pathological anatomy and professor at Padua. See ANATOMY.

Morgan, MOUNT. See MOUNT MORGAN.

Morgan, AUGUSTUS DE. See DE MORGAN.

Morgan, CONWY LLOYD, was born in London, 6th February 1852, and educated at Guildford and at the Royal College of Science, London. In 1878-83 he was lecturer in English and Physical Science at Rondebosch, near Capetown; in 1884 was appointed professor of Zoology and Geology in University College, Bristol; in 1887 became principal; and in 1909 for three months was first vice-chancellor of the university of Bristol. Among his works are *Animal Biology* (1887), *Animal Life and Intelligence* (1890), *Introduction to Comparative Psychology* (1895), *Habit and Instinct* (1896), *Animal Behaviour* (1900), *Instinct and Experience* (1912), *Emergent Evolution* (1923).

Morgan, SIR HENRY. See BUCCANEERS; also J. C. Hutcheson, *Sir Henry Morgan* (1890), and Haring, *The Buccaneers in the West Indies* (1910).

Morgan, LADY, novelist, was born (Sydney Owenson) in Dublin on the Christmas-day of 1780 or thereby—'cold, false, erroneous, chronological dates' she protests against. Her father, a theatrical manager, fell into difficulties; and the clever, bold, lively young woman resolved to support the fortunes of the family, first as governess, afterwards as author. She had had 'somewhat mysterious relations' with at least one admirer, Sir Charles Ormsby, when in 1812 she was married off-hand to Thomas Charles Morgan, M.D. (1783-1843), whom the Lord-lieutenant knighted for the occasion. For the next quarter of a century, excepting two long visits to the Continent, the pair made Dublin their home; but in 1837 Lord Melbourne gave her a pension of £300, and next year they removed to London. Here she died on 16th April 1859, having continued busy with her pen and her tongue to the last. Her twenty-two works—rattling novels, verse, travels, &c.—include *St Clair* (1804), *The Wild Irish Girl* (1806), *O'Donnel* (1814), *France* (1817), and *Italy* (1821). Her silly but not unamusing *Memoirs* were edited by Hepworth Dixon (2 vols. 1862).

Morgan, LEWIS HENRY, an American archaeologist, was born at Aurora, New York, 21st November 1818, graduated at Union College in 1840, and became a lawyer at Rochester. He served in the state assembly (1861) and senate (1868), and died 17th December 1881. Morgan's earliest work, *The League of the Iroquois* (1851), was the first account of the organisation and government of an Indian tribe; but even more valuable are his *Systems of Consanguinity and Affinity of the Human Family* (1869), and his treatise on *Ancient Society* (1877). He also published *Houses and House-life of the American Aborigines* (1881), and an account of the beaver.

Morgana, FATA. See FATA MORGANA.

Morganatic Marriage (perhaps from Goth. *morgan*, 'to limit'; perhaps Ger. *morgengabe*, a gift given by the husband to the wife after marriage; Littré suggests *morgen*, 'morning'—a wedding celebrated privately in the morning), sometimes called *Left-handed marriage*, a lower sort of matrimonial union, which as a civil engagement is completely binding, but fails to confer on the wife the title or fortune of her husband, or on the children the full status of legitimacy or right of succession. In Germany it came in very early times to be accepted as a principle that *Ebenbürtigkeit*, or equality of birth between husband and wife, was essential to a proper marriage. The lower nobility were of course not *ebenbürtig* with the higher nobility, nor the best born commoners with the lower nobility. Later, the rule came to concern only reigning houses and the higher nobility. But members of German princely houses entering into marriages of this kind with their inferiors in rank (as frequently happened) contracted merely morganatic unions. The marriage, for instance, in 1851 of Prince Alexander of Hesse to the Countess Julie von Hauke, from which sprang the Battenberg family, was a morganatic one.

Morgan Library, a collection of early printed books and manuscripts, mostly literary in character, made in a measure secretly in the last years of his life by John Pierpont Morgan (1837-1913), the United States banker and financier, and housed by him in a fine marble building designed by Charles F. McKim, and situated near Madison Avenue, New York. In 1924, as a memorial to his father, the library was handed over by Morgan's son to trustees for the public, together with an

endowment of about £300,000. The collection is said to number some 20,000 volumes, and in its kind is among the most noteworthy in the world; at the time of its bequest it was valued at about £1,000,000. Here in printed books is work by Caxton and all the early English printers (sixty Caxtons out of a possible hundred, nearly all the early English Bibles, and other works), by Fust and Schöffer, by Fust and Gutenberg, the Elzevirs, and the Aldine Press; some twenty Shakespeare quartos in addition to folios. The manuscripts include the illuminated Ashburnham *Evangelarium* (9th cent.), 15th century manuscripts of Richard de Bury, Chaucer, and Gower; the only known manuscript fragment of *Paradise Lost*, which, though not in the author's hand, is the 'copy' from which the poem was set up.

Morgarten, a mountain slope on the east margin of Lake Egeri, in the canton of Zug, Switzerland, is the place where 1400 men of the Swiss Forest Cantons—Schwyz, Uri, and Unterwalden—won a great victory over 15,000 Austrians, 15th November 1315.

Morghen, RAPHAEL SANZIO, a famous engraver, was born at Naples, 19th June 1758, of German family. After some instruction from his father, a mediocre engraver, he studied at Rome under Volpato, then considered the best engraver in Italy, whose daughter he married in 1781. Even his first works obtained great success. Raphael's celebrated figures in the Vatican of 'Poetry' and 'Theology' were engraved by him in 1781; and he afterwards produced a succession of engravings of a very high class from many of the masterpieces of art: amongst these may be mentioned Raphael's 'Madonna della Seggiola' and the 'Transfiguration'; the 'Madonna del Sacco,' by Andrea del Sarto; the 'Duke of Moncado,' by Van Dyck; and Da Vinci's 'Last Supper.' The grand-duke gave him a pension at Florence, where he died 8th April 1833. His *Life*, with a catalogue of 254 works, was published by his pupil, Niccolò Palmerini. He will always hold a very prominent place in the history of Engraving (q.v.).

Morgue, a mortuary in Paris (q.v.), now demolished.

Moriche, a tropical American palm (*Mauritia flexuosa*). See PALM.

Morier, JAMES (1780?-1849), novelist, born at Smyrna, served from 1809 to 1816 at the court of Persia, first as secretary of legation, subsequently as envoy. In 1812 he published his *Persia, Armenia, and Asia Minor to Constantinople*, and in 1818 *A second Journey through Persia, Armenia, and Asia Minor*. The minute and familiar acquaintance he had acquired with the manners and customs of the Persians was seen in his highly-interesting series of Eastern romances: *The Adventures of Hajji Baba of Ispahan* (1824), *Hajji Baba in England, Zohrab, Ayesha, and The Mirza* (1841).—SIR ROBERT MORIER, G.C.B. (1826-93), British diplomat in Germany, Spain, and Russia, was his nephew. See *Life* by his daughter (1911).

Mörke, EDUARD (1804-75), regarded by some German critics as one of their greatest lyrists, was born at Ludwigsburg, and became a pastor at Tübingen and a professor of German Literature at Stuttgart. By a succession of volumes of poetry he made good his claim to rank as one of the foremost of the Swabian school.

Morin, JEAN (or MORINUS; 1591-1659), head of a college at Angers, wrote on ecclesiastical antiquities and the Samaritan Pentateuch.

Moringa. See BEN (OIL OF).

Morion. See ARMOUR.

Moriori. See CHATHAM ISLANDS.

Moriscos is the name given to the Moors who remained in Spain after 1492; Mozárabes or Muzárabes, to the Christian Spaniards who lived in the parts of Spain under Moorish rule; Mudéjares, to the Moors who submitted to the Christians in the earlier periods of the re-conquest.

To take first the *Mozárabes*. Christianity was freely, if contemptuously, tolerated under the Moorish rule. Occasional outbursts of fanaticism used to take place. These were often provoked by Christians defiantly seeking martyrdom, as in Córdoba in the 9th century; this persecution lasted intermittently till 953, when it well-nigh ceased. The Mozárabes kept their ancient liturgy, though many of them had ceased to understand Latin, and spoke and wrote Arabic only, writing even Latin and Spanish with Arabic characters. They occasionally held councils, but indifference prevailed, and the Spanish conquerors were more astonished at the laxity of the Mozárabes than at their constancy in retaining their old faith. For Mozarabic liturgy, see LITURGY.

Mudéjares.—Moorish names appear first in the 9th century as inhabitants of the country, and witnesses to documents, under Spanish rule. One of the earliest capitulations or fueros granted to them is that of Huesca (1081); by this and subsequent fueros (Tudela, 1115, &c.) the widest toleration was extended to them; they were allowed full exercise of their religion, laws, language, dress, and customs. The fuero of Játiva granted by Jaime I. of Aragon (1251) even provides that if any Saracen should become a Christian he should lose his landed property; that of Siliebar, near Seville (1255), allows them to build a castle for their defence. These capitulations seem to have been fairly observed till the 14th century, when a change of tone becomes apparent. In 1301 the Moors of Aragon were compelled to wear a distinctive dress, and in the next century their privileges were greatly curtailed; recantation was forced upon them. The Mudéjares of Aragon, Valencia, and Castile had hitherto been faithful, had served loyally in war even against Moors, had taken the royal side in all popular movements; even as late as 1528 they appealed to their well-proved loyalty to the crown.

But their situation was greatly impaired by the incorporation among them of the *Moriscos*, after the fall of Granada (1492). The terms of the capitulation of Granada were to the full as liberal as those under which the Mudéjares had lived loyally in Aragon, Valencia, and Castile for three or four centuries. Under Talavera, the first Archbishop of Granada, some attempt was made to observe these conditions, and with happy results. But the bigotry of Cardinal Ximenes, violating the capitulation, led to a rising in the Alpujarras (1500-2) and to the expulsion of the Moriscos of Castile and León; though in 1503 and in 1510 Ferdinand forbade the expulsion of those of Aragon and Valencia. At the close of the rising in the Alpujarras the alternative of exile or of baptism had been offered to the Moriscos. Those who chose exile went to swell the number of the Corsairs of Algeria and the Barbary States, who were henceforth a standing danger and annoyance to Spain. The newly-converted Moriscos (New Christians as they were called) became the objects of the severities of the Inquisition; as doubtful Christians they were regarded with greater jealousy and suspicion than as professed Mohammedans. Under danger of relapse their children were taken from them, and their young men sent to the galleys. In the war of the Germanias in Valencia (1520) they were ruthlessly massacred by the populace, but were still faithful to the king and to the nobles who respected their privileges. The ever-increasing

persecution provoked a still more serious rising under Philip II. in Granada. It was put down after two years of warfare by Don John of Austria (1568-70); many of the Moriscos, and especially the women, were given to the soldiers as slaves, and the rest, who did not emigrate, were removed to Castile, Valencia, and Murcia. The action of the Corsairs, avenging on Spain the wrongs of their fellow-countrymen, ruining the commerce, carrying off Christian captives, ravaging the coasts so that for leagues along the south-east it remained uncultivated, increased the bitterness against the Moriscos, who were suspected of being in league with the Corsairs, and directing their forays. Many returned openly to their ancestral faith; spasmodic attempts at genuine conversion proved fruitless; in 1599 the Archbishop of Valencia reported the conversion of one Morisco woman only as the result of a year's labour. Harsher measures were tried and failed; persecution only made them cling more firmly to their faith; partial expulsion only augmented the number of the Corsairs; and at last they were forbidden to leave the country by sea. The hatred, however, of Philip II. against the Protestants was stronger than his dislike of the Moriscos, and his reign is marked by constant vacillations in his policy towards them; and their lot cannot have been absolutely intolerable, for one charge against them was that their numbers increased continually while that of the old Christians diminished. The fear and suspicion aroused on both sides made it difficult for Spaniards and Moriscos, new and old Christians, to live together. After so many breaches of faith the Moriscos could trust no promise made to them by king or church. To the Spaniards it seemed intolerable to have an intestine foe, while the kingdom was so sorely pressed from without; and churchmen taught the king that anything, short of the extermination which he might commit with a safe conscience, was a mercy. In 1582 the total expulsion was first mooted; it was decided on in principle in 1599. In 1609-10 the whole of the Moriscos were expelled the kingdom, either by sea from Valencia, or through the Pyrenees from Aragon and Castile. All their goods were confiscated, except what they could turn into money, or carry with them on their persons; robbery, murder, assault, excesses of every kind against them marked their track; all their children under four years of age were taken from them to be brought up as Christians; over 500,000 Moriscos, chiefly agricultural labourers or farmers, left the country in which their people had dwelt for so many centuries. The results to Spain were like those which subsequently followed the emigration of the Huguenots from France. Even this does not end the story; the descendants of the children forcibly kept behind, or of those really converted to Christianity, were regarded with horror, and were constantly denounced to the Inquisition. For nearly a century afterwards we find decrees of particular provinces expelling families for being descendants of the Moriscos. A taint of Moorish blood was sufficient to prevent the holding of any public office, even in the smallest municipality.

See *Guerra de Granada*, by Diego de Mendoza; *Rebelión y Castigo de los Moriscos del Reino de Granada*, by L. del Mármol y Carvajal (both in vol. xxi. of Rivadeneira's *Biblioteca de Autores Españoles*); *Estado Social y Político de los Mudéjares de Castilla*, by F. Fernández y González (1866); books on them by Florencio Janer (1857) and Danvila y Collado (1889); and *The Moriscos of Spain, their Conversion and Expulsion*, by Henry D. Lea (1901).

Morison, JAMES COTTER, author and Positivist, was born in 1832, son of the inventor of 'Morison's pills,' and educated at Highgate gram-

mar-school and Lincoln College, Oxford. His first work was his masterpiece, *The Life and Times of St Bernard* (1863). His latest, *The Service of Man, an Essay towards the Religion of the Future* (1887), attracted much attention, but it was commenced when sickness had already seized him, and it does not adequately represent his views. He was one of the founders and first proprietors of the *Fortnightly Review*. His intellectual gifts were associated with a most genial and kindly nature; he was reputed one of the best talkers of his time in French as well as English, and had long projected a work on the history of Louis XIV.'s reign, but owing to ill-health it was never fairly begun. He died 26th February 1888.

Morison, ROBERT, botanist, was a native of Aberdeen, born in 1620. Having borne arms as a royalist in the civil wars, he retired to France when his sovereign's cause collapsed, and took the degree of doctor at Angers (1648). Two years later he became superintendent of the garden formed at Blois by Gaston, Duke of Orleans. After the Restoration he was appointed by Charles II. one of his physicians, 'botanist royal,' and 'professor' of Botany at Oxford. He was knocked down by a coach in London, and died the following day, 10th November 1683. His chief work is *Plantarum Historia Universalis Oxoniensis* (1680).

Morisonianism. See EVANGELICAL UNION.

Morlaix, a picturesque and flourishing port of France, in the Breton department of Finistère, on the tidal Dossen, 6½ miles from the sea and 38 ENE. of Brest. It has many quaint timbered houses, a huge railway viaduct 207 feet high, and manufactures tobacco, paper, &c. Moreau was a native. Pop. 15,000. See BERNARD OF MORLAIX.

Morland, GEORGE, painter, was born in London, 26th June 1763, the eldest son of Henry Morland, crayonist (1712-97), to whom at fourteen he was articulated for seven years, and who brought him up with extreme rigour. No sooner, then, had he become his own master than he went hopelessly and utterly to the bad. His marriage in 1786 had no power to check him; and his whole after-life was a downward course of debt and dissipation. He was regular only in this, that 'every day he got thoroughly intoxicated, and then generally would lie all night long on the floor.' Yet he worked hard and rapidly, in the last eight years of his life turning out nearly nine hundred paintings and more than a thousand drawings. His strength lay in country subjects (pigs, Gypsies, and stable interiors); his sea-pieces are not so good. He died of brain-fever in a sponging-house, 27th October 1804. See Lives by Dawe (1807), Richardson (1895), and Williamson (1904).

Morley, a municipal borough, since 1918 part of Batley and Morley parliamentary borough, in the West Riding of Yorkshire, 5 miles SW. of Leeds, with woollen manufactures, glass-works, tanneries, coal-mines, and stone quarries. Mentioned in Domesday, it became a borough only in 1885. The Earl of Oxford (Mr Asquith) was born in Morley. Pop. (1851) 4821; (1921) 23,934.

Morley, HENRY (1822-94), was born in London, and educated at King's College there, practised medicine at Madely, Shropshire, in 1844-48, taught a school in 1848-50 at Liscard, and was joint-editor or editor of the *Examiner* from 1856 till 1864. For eight years English lecturer at King's College, he was in 1865-89 professor of English Literature at University College, London. In 1889 he contributed the article on English Literature to this work. His writings include lives of Palissy (1852),

Cardan (1854), and Cornelius Agrippa (1856); *Memoirs of Bartholomew Fair* (1857); *English Writers to Dunbar* (part of a projected history of English literature in 20 volumes); *Clément Marot and other Studies* (1871); a very popular *First Sketch of English Literature* (1873; 14th ed. extended by Edmunds, 1912); *Library of English Literature* (5 vols. 1876-82); and *English Literature in the Reign of Victoria* (1881). He edited several popular libraries of reprints (Morley's Universal Library, 63 shilling vols.; Cassell's National Library, 214 vols. at threepence; and the Carisbrooke Library). See Life by H. S. Solly (1898).

Morley of Blackburn, JOHN, VISCOUNT, born the son of a surgeon at Blackburn, 24th December 1838, graduated from Lincoln College, Oxford, in 1859, where the Tractarian movement had been followed by a movement in the direction of Liberalism, and young Morley came under the influence of J. S. Mill. Embarking on a literary career, he was, after a few preliminary ventures, appointed editor of the *Fortnightly Review*; and from 1880 he edited the *Pall Mall Gazette*, the leading organ of advanced Liberalism, and the *Pall Mall* till, in 1883, he was sent to parliament by Newcastle. His articles and speeches in favour of Home Rule did much to prepare the way for Gladstone's new policy. In 1886, and again in 1892, he was Secretary for Ireland in Gladstone's Home Rule administrations. In 1895 he lost his seat through his opposition to the compulsory eight hours' day for miners, then regarded as Socialistic; but in 1896 he re-entered parliament as member for the Montrose Burghs. In 1905 he was made Secretary of State for India, entering the House of Lords as Viscount Morley of Blackburn in 1908; in 1910 he took the less fatiguing post of Lord President of the Council. As Indian Secretary he had the ungrateful task of firmly suppressing sedition (not without protest from extreme Radicals), but was able to make a welcome concession to the desire of the natives of India to have a larger share in the government of their own country. Not seldom in public life he took the unpopular side; but by the force of his personality and his steadfast adherence to his principles he retained the respect of those who differed most widely from him. He was Lord President of the Council from 1910 till 1914, but he retired from the government and from public life on the outbreak of war. He died 23d September 1923. To the study of modern problems he carried the spirit and methods of Philosophical Liberalism. Alike in his writings and his public life, he accepts in the main the leading conceptions of the Philosophic Liberals—a belief in individual and social progress along the lines of freedom and knowledge, progress being accelerated by the growth of justice and sympathy; and his intense interest in the progress of humanity explains his antipathy to 'Imperialism'—he opposed both the Sudan expeditions and the South African War policy. Evolution, not revolution, is the keynote of his thinking; and by his deep historic sense, his fondness for the concrete, his vital interest in humanity, apart from philosophic shibboleths, he became an exponent of evolutionary Liberalism.

His philosophy of life must be gathered from a study of his writings, of which that *On Compromise* (1874) is one of the most characteristic. In his *Voltaire* (1872) we have his attitude towards religion. In his *Diderot and the Encyclopædists* (1873) he insisted on the paramount importance of knowledge and freedom as the two vital factors in progress, a generous tribute being paid to the advanced thinkers of the Revolution period. In *Rousseau* (1873), along with appreciation of Rousseau's influence, he protested against the dangers

of importing into political life sentimentalism and intuitionism. His *Burke* (1879) sketches the ideal politician, in whom the desire for progress is held in check by a profound regard for the principles of order and continuity. In his *Life of Cobden* (1881) he elucidates those great politico-economic principles which tend to internationalise commerce and industry. Four series of *Miscellanies* (1871-1908), a volume of *Studies in Literature* (1891), his *Machiavelli* (1897), and his *Recollections* (1917) are part of his literary legacy; and the *Oliver Cromwell* (1900) showed how fairly he could deal with a man and a movement dominated by religious conceptions he does not share. In his *Life of Gladstone* (3 vols. 1903), a literary as well as a political masterpiece, the history of the time is depicted with superb and attractive lucidity, while Gladstone all through remains the central figure.

See *Viscount John Morley: An Appreciation*, by J. H. Morgan (1924); Ali Khan, *Life of Lord Morley* (1923); and a criticism of Morley as a writer and thinker by P. Braybrooke (1924).

Morley, SAMUEL (1809-86), born in Homerton, became head of his father's hosiery business in 1854. He was returned to parliament for Nottingham as a Liberal in 1865; represented Bristol in 1868-85, and declined a peerage. Identified with many religious and philanthropic movements, he gave largely towards the erection of Congregational chapels and institutions.

Morley, THOMAS, English composer, was born in 1558. He was a pupil of Byrd, and in 1588, when he seems to have been organist at St Giles', Cripplegate, graduated in music at Oxford. Shortly thereafter he would appear to have been organist at St Paul's, and there is evidence that for a time he served in Flanders as some sort of anti-Catholic secret political agent. In 1592 he entered the Chapel Royal, and was successively epistler and gospeller, but resigned in 1602, almost certainly on account of ill-health, and died probably in 1603. In 1598 he had obtained a twenty-one year's monopoly of song-book production. Morley's outstanding work was done in vocal secular music, and, if he was not the founder of the English madrigal school, he was certainly its leading personality, and in a sense its father. Between 1593 and 1597 he produced three volumes of canzonets (1593, 1595, 1597), one volume of madrigals (1594; here the word 'madrigal' is for the first time used in English on a title-page), and one volume of ballets (1595), a form of musical composition Morley was the first to introduce into England. Thereafter he edited a collection of canzonets from Italian composers (1597), and two collections of madrigals, the first (1598) from Italian composers, the second (1601) the well-known *Triumphs of Oriana*; except in the volume of 1598, various pieces of his own were included in these works. Morley's vocal compositions, some 200 in all, many based on original treatment of borrowed Italian matter, and all fresh and distinguished in harmony, in phrasing, in melody, and in general workmanship, reflect the light-hearted spirit of the composer; and in this vein, to which almost exclusively he confined himself, Morley was unrivalled among the English madrigalists. Notable among his vocal pieces are 'April is my mistress' face,' 'Now is the month of maying,' 'My bonny lass, she smileth,' 'Fire! fire!' 'I follow, lo, the footing,' 'Stay heart, run not so fast,' and 'Miraculous Love's wounding,' which last forecasts what came to be known as ternary form. In other fields of composition Morley also did work of note: virginal music by him is in the *Fitzwilliam Virginal Book* and elsewhere; his lute-song set of the year 1600 contains 'It was

a lover and his lass,' rare as an undoubtedly authentic original setting of a Shakespeare song; while in sacred music he wrote various services, anthems, and motets; and edited, with four pieces by himself, *The whole Booke of Psalmes* (no date). In addition to musical composition Morley wrote his celebrated *Plaine and Easie Introduction to Practicall Musicke* (1597), a text-book in dialogue form, containing much sound instruction, as well as some musical examples of his own composition; for many generations it had no rival as a work on modal music, and it may still be studied with advantage; it pleasantly reflects, too, the personality of its author, and is valuable also for the sidelights thrown on contemporary musical life. Among his contemporaries Morley enjoyed high popularity and repute, and he is unquestionably to be ranked among the greatest of the Elizabethan composers. See Fellowes, *The English Madrigal Composers* (1921), and for Morley's madrigal and kindred compositions four volumes (1913) in *The English Madrigal School* (ed. Fellowes).

Mormaer, the better spelling of the Gaelic *mormhaor*, often spelt *maormor*. See EARL.

Mormons, or, as they call themselves, the Church of Jesus Christ of Latter-day Saints, an organisation founded by Joseph Smith, born, the son of a farmer, at Sharon, Vermont, on 23d December 1805, who at ten removed with his parents to Palmyra, New York, and four years later to Manchester. There he claimed to have received in 1820 a divine call as a prophet of the Most High; and on the evening of 21st September 1823 a glorious messenger from the presence of God appeared at his bedside and called him by name. 'He said there was a book deposited, written upon golden plates, giving an account of the former inhabitants of this continent, and the source from whence they sprung. He also said that the fullness of the everlasting gospel was contained in it, as delivered by the Saviour to the ancient inhabitants. Also, that there were two stones in silver bows deposited with the plates, and the possession and use of these stones was what constituted seers in ancient or former times, and that God had prepared them for the purpose of translating the book. . . . While he was conversing with me about the plates, the vision was opened to my mind that I could see the place where the plates were deposited, and that so clearly and distinctly that I knew the place again when I visited it.' This visitation was supplemented by others, the same angel appearing to him thrice that night, and afterwards paying him several visits and instructing him at length in relation to his prophetic mission. The spot where the records lay concealed was described as being 'on the west side of a hill, not far from the top, about 4 miles from Palmyra, in the county of Ontario, and near the mail-road which leads thence to the little town of Manchester.' Thither the youth repaired the next day, and was shown the plates as he had been promised, but was not permitted to take them. Four years later, however, after due disciplinary probation, on the night of September 22, 1827, the angel of the Lord delivered the sacred records into his hands. They were engraved on plates nearly 8 inches long by 7 wide, a little thinner than ordinary tin, and bound together by three rings running through the whole. The volume was altogether about 6 inches in thickness, a part of which was sealed. The characters, letters, or hieroglyphics upon the unsealed part were small and beautifully engraved. They represented an unknown language, which Mormons have called the 'Reformed Egyptian.' Along

with them were found the Urim and Thummim, described by the angel; by means of this instrument, which is said to have borne some resemblance to a pair of spectacles, the Lord enabled the young man to translate the ancient records into English. He read off by the aid of the Urim and Thummim to his associate and scribe, Oliver Cowdery, or other clerks, who wrote down the words exactly as he gave them. The first edition of the *Book of Mormon* (5000 copies) was published at Palmyra, New York, in 1830. It contained a prefatory testimonial, signed by Oliver Cowdery, David Whitmer, and Martin Harris, to the effect that an angel of God came down from heaven and showed them the plates from which Joseph Smith translated the *Book of Mormon*; and this was followed by the testimony of eight other witnesses, among them Joseph's father and two brothers, who affirmed that 'Joseph Smith, junior,' had shown them the golden plates containing the engravings. These were the only persons who were permitted to see them. They were returned to the angel after the work of translation was done. Only the unsealed portion of the plates was translated, the sealed remainder being reserved, with a promise of translation at a future time.

These records contain the primitive history of America from its settlement by a colony that came from the Tower of Babel, at the time of the confusion of tongues, to the beginning of the 5th century of the Christian era. These primitive colonists of North America were called Jaredites. They were a race highly favoured of heaven, but degenerated and became wicked and corrupt, the sun of their civilisation finally setting in a sea of blood and civil strife, in which millions of souls were slaughtered. But a new race came directly from Jerusalem about 600 B.C., and in time peopled both North and South America. The founders of the new colony were Lehi and his wife, his four sons Laman, Lemuel, Sam, and Nephi, with their wives; Zoram, a servant, and his wife; in all sixteen persons. They landed on what is now the coast of Chili, in South America. After Lehi's death quarrels broke out among the brothers. The Lord had appointed Nephi to be the ruler of the new race of colonists, but his jealous elder brothers rebelled, and were cursed by the Almighty for their iniquities, and condemned to have dark skins, this punishment to continue in their posterity. They became 'an idle people, full of mischief and subtlety, which did seek in the wilderness for beasts of prey.' They were known as Lamanites, and, according to the *Book of Mormon*, were the ancestors of the American Indians. The Nephites became highly civilised and prosperous, were fair and beautiful to look upon, and were greatly blessed of the Lord, though often ungrateful for his goodness. Both Nephites and Lamanites increased and multiplied, but were almost continually at war with each other. About the time of the Crucifixion, awful earthquakes, darkness, and destruction announced that event. Shortly afterwards Christ himself appeared out of heaven to the more righteous Nephites. He showed them his wounded side and the print of the nails in his hands and feet, instructed them in the truths of his gospel, healed the sick, blessed children, administered the sacrament, chose twelve apostles, and gave them power to found his church with the same orders of priesthood, the same ordinances, gifts, powers, and blessings as in the Old World. After a prolonged season of peace, the result of the spread of the work of Christ, which at one time was received by both Nephites and Lamanites, hostilities between the two races were resumed, gradually the purity of their faith

declined, and finally, about the year 385 A.D., a decisive conflict, similar to that which had destroyed the Jaredites in the same locality, took place near the hill Cumorah, where the Nephites were almost totally annihilated. The Lamanites remained a dark and benighted race, to people the waste of ruin, and faintly perpetuate in their customs and traditions the story of the illustrious past. Shortly before the battle of Cumorah, a Nephite prophet named Mormon had been commissioned of God to write an abridgment of the history of his people, from the records kept by their various prophets and rulers, to be hidden in the earth till God should see fit to bring it forth and 'unite it with the Bible for the accomplishment of his purposes in the last days.' This abridgment, written upon golden plates, was concealed in the hill by Moroni, a son of Mormon, and one of the survivors of the battle of Cumorah. He it was who appeared as an angel to Joseph Smith and told him where the plates were deposited. Such is the famous *Book of Mormon*, believed by the Latter-day Saints (hence called Mormons and Mormonites) to be of equal authority with the Jewish and Christian scriptures, and to form an indispensable supplement to them, containing God's revelations to the New, as the others to the Old World.

The work being published, attention was speedily drawn to it. The opponents of the Saints alleged that it was made up from a romance written by a quondam clergyman named Solomon Spaulding (1761-1816). This the Mormons emphatically deny, and the discovery of the original MS. of that romance by President Fairchild of Oberlin College, 1884, corroborates their denial. Undeterred by ridicule and hostility, the Mormon prophet and his associates declared that the millennium was nigh at hand, that the Indians would soon be converted, and that the new Jerusalem, the Zion of the last days, where the Saints would finally gather to prepare for the coming of the Lord in his glory, was to be built in the heart of the American continent. America, they claimed, was the land of Joseph, bestowed upon him and his posterity for ever by the blessing of the patriarch Jacob, as recorded in Genesis and Deuteronomy. The prophet's house was frequently beset by mobs and 'evil-designing persons'; several times he was shot at and very narrowly escaped; but his courage and zeal continued to bring him disciples, and on April 6, 1830, the Church of Jesus Christ of Latter-day Saints was legally organised, with six members, at the house of Peter Whitmer, in Fayette, Seneca county, New York. Several months prior to this the Aaronic priesthood, restored by an angel who said that he was John the Baptist, was conferred upon Joseph Smith and Oliver Cowdery, and later they were ordained to the Melchizedek priesthood by the apostles Peter, James, and John. The new religion spread rapidly and gained many converts. Branches of the church were established in New York, Pennsylvania, Ohio, the British provinces, and the New England states. The prophet was fiercely attacked by the leaders and preachers of the other religious denominations, but held his ground firmly. Though but poorly educated, he was a formidable opponent in the polemical field. In January 1831, in compliance with revelation, the church removed westward and established its headquarters at Kirtland, Ohio, where it began to thrive amazingly. In the summer of 1831 a colony from Kirtland migrated to Missouri, where they purchased lands in Jackson county, which had been revealed to the Mormon prophet as the chosen site for the city of Zion. At a place called Independence his colonists concentrated them-

selves, established a printing-press, started a monthly periodical, the *Evening and Morning Star*, and continued to preach zealously and make proselytes to their faith. Their success and rapid increase here, as elsewhere, raised up enemies. Secret societies were formed to expel them from Missouri, their houses were attacked by mobs, their periodicals were stopped, their printing-press confiscated, their bishop tarred and feathered, and numberless other outrages committed against them. Finally, in the autumn of 1833, the entire community, numbering about 1500 souls, were driven from their homes, whipped, plundered, many of them killed, and the survivors expelled from Jackson and scattered through the adjoining counties. The main body of the refugees found a resting-place and kindly welcome in Clay county.

Meanwhile the Saints in Ohio had suffered some persecution. On the night of March 5, 1832, at Hiram, Portage county, a mob broke into a house where the prophet was sleeping, tore him from the arms of his wife, hurried him to an adjoining meadow, tarred and feathered him, and forced aqua fortis into his mouth. Sidney Rigdon, his associate, was similarly handled and rendered temporarily insane. Later on Smith was assailed by divers vexatious prosecutions, but each time came off victorious. He set up a mill, a store, and a bank in Kirtland, and continued his propagandist labours with great success. In June 1833 the building of a temple in Kirtland was commenced. Shortly afterwards a printing-press was established in the city, and Oliver Cowdery recommenced the publication of the *Evening and Morning Star*. In July 1834 the Mormon prophet visited for the third time his people in Missouri. He was accompanied by 204 persons, mostly young men. This was the 'Zion's Camp' expedition, the object of which was to relieve the wants of their afflicted brethren who had been driven from their homes in Jackson county, and, if possible, effect a reconciliation between them and their former neighbours. They purchased lands in Caldwell county, Missouri, where they settled and founded the city of Far West. At Kirtland on February 14, 1835, the Twelve Apostles of the church were chosen, and soon after the council of the Seventies, their co-labourers in the ministry, was called into existence, and sent forth with the apostles to begin the work of 'pruning the Lord's vineyard for the last time.'

In June 1837 Heber C. Kimball, Orson Hyde, Willard Richards, Joseph Fielding, and others left Kirtland for England, and landed at Liverpool, July 20. Three days later they began preaching in Preston, and met with such remarkable success that within the next eight months, at the expiration of which time Kimball and Hyde returned to America, they had converted and baptised about 2000 people. The British mission was the first foreign mission of the Mormon Church.

On account of apostasy and persecution Kirtland was now pretty much abandoned by the Saints, the main body of them with the prophet and other leading elders migrating to the new 'Stake of Zion' in Missouri. They settled in Caldwell, Daviess, Clinton, Carroll, and Ray counties, where they bought land and improved it. At Far West, Caldwell county, the corner-stone of a temple was laid, a printing-office was established, and a monthly paper, called *The Elder's Journal*, published. But an election riot in August 1838, in Gallatin, Daviess county, where attempts were made to prevent the Mormons from voting, and some of them were obliged to defend themselves against assailants, was made the pretext for further acts of violence and rapine, from which the Saints in the outlying settlements were sufferers. The mob even burned the

houses and laid waste the property of some of their own sympathisers in order to make it appear the work of the Mormons, who were falsely accused of deeds similar to those of which they were the victims. The result was a general uprising. The militia of the state was called out to suppress the riots, but took side with the mob against the unpopular Mormons. Governor Boggs issued an order for them to be 'exterminated or driven from the state,' and commanded Major-general Clark with several thousand troops to proceed at once to Far West and execute the decree. To this overwhelming force the inhabitants of the city peaceably surrendered, though compelled to look on and see their city sacked and pillaged, their wives and daughters outraged and insulted, and a number of their brethren killed by the mob and the soldiery. The Mormon leader and about seventy others were retained as prisoners, and the body of their followers, on penalty of death, ordered to leave the state forthwith. From twelve to fifteen thousand people in the autumn and winter of 1838 crossed the Mississippi, and were kindly received in the neighbouring state of Illinois. Joseph Smith and the other prisoners were tried by court-martial (November 1) and condemned to be shot, but escaped execution.

The Mormon prophet next rallied his people on the banks of the Mississippi, principally at or near Commerce, Hancock county, Illinois, where they again purchased homes and founded the city of Nauvoo (q.v.). This region though naturally fertile was then a mere wilderness, but Mormon thrift and industry soon made it 'blossom as the rose.' The legislature of Illinois granted a liberal charter to Nauvoo, and a body of Mormon militia was formed under the name of the 'Nauvoo Legion,' with the prophet himself as its commander. Meantime the Twelve Apostles, with Brigham Young at their head, had preached a wonderfully successful mission in the British Isles, whence they sent many hundreds of converts across the Atlantic. Within five years the Mormons numbered in Illinois about 20,000 souls.

After a few years of comparative peace and prosperity the tempest of persecution again burst upon the Mormon community. Governor Ford ordered into service several hundred men, had Joseph Smith arrested with his brother Hyrum, and immured in Carthage gaol, Willard Richards and John Taylor accompanying them. In the afternoon of June 27, 1844, a mob of about 150 men with blackened faces broke into the gaol and shot the two brothers Smith dead, also severely wounding John Taylor. The assassins were never brought to justice. Mormonism was now thought to be doomed, but under the leadership of Brigham Young it survived the shock of its prophet's martyrdom: 'the blood of the martyrs' proved, as ever, to be 'the seed of the church.' But the anti-Mormons were determined on the removal of the entire community of Latter-day Saints from the state, and the Mormon leaders, seeing no alternative but to comply with this demand or experience a repetition of the murderous scenes of Missouri, finally resolved once more to abandon their homes, and seek a haven of peace and safety in or beyond the Rocky Mountains. Accordingly, on 1st February 1846 a thousand families left Nauvoo, crossing the Mississippi on the ice. At Council Bluffs, on the Missouri River, in the month of July 1846, Captain J. L. Allen of the United States army called on the Mormons to raise a battalion for service in the Mexican war. The exiles speedily raised the five hundred troops required, though it took nearly all their able-bodied men. The families left at Council Bluffs, unable in the absence of the battalion to proceed farther that season, crossed the Missouri and established 'Winter Quarters,' now Florence, Nebraska. Mean-

while the residue of the community left behind in Nauvoo, after a gallant defence of their city against the mob, which in violation of treaty came upon them in overwhelming numbers, were expelled from their homes and thrown shelterless upon the western shore of the Mississippi.

In the spring of 1847 Brigham Young at the head of a picked band of pioneers, 143 men, 3 women, and 2 children, started from Winter Quarters for the Rocky Mountains. They arrived in the valley of the Great Salt Lake, the site of their present beautiful city, on July 24, and began to plough the ground and put in crops the same day. Seven hundred more wagons arrived that autumn, and 1000 wagons in the autumn of 1848. In December 1847 Brigham Young was chosen president of the church—an office left vacant since the death of Joseph Smith—with Heber C. Kimball and Willard Richards as his counsellors in the First Presidency. In 1849 the provisional government of the state of Deseret was organised at Great Salt Lake City, a state constitution adopted, and a delegate sent to congress to ask for admission into the Union. The petition was refused, but in September 1850 congress created Utah a territory, and President Fillmore appointed Brigham Young governor, which office he held from 3d February 1851 until 11th April 1858, when he was succeeded in that office by Alfred Cumming. In 1857 the Mormons were falsely charged with being in a state of rebellion against the government, and President Buchanan sent a considerable military force to Utah. Young and his people fearing military excesses, and remembering the fate of Far West and Nauvoo, kept the army east of the Wasatch Mountains until the next spring, when arrangements were made for the peaceable entry of the troops, the Mormons having abandoned their city and surrounding parts and removed south, with the avowed determination of burning every building and reducing Utah to its former condition of barrenness if vindictively pursued. They were not, however, molested. The troops passed quietly through the city and encamped in Cedar Valley, about 40 miles south-west, and the people returned to their homes. Since then their cities and settlements have extended from Idaho through Utah into Wyoming, Colorado, Nevada, Arizona, New and Old Mexico. The Mormons also have a settlement in British America.

The Mormons have sent many missionaries to the British Isles and nearly every other European country, also to Australasia, Africa, Palestine, the East and West Indies, China, Burma, Siam, South America, and the Society, Sandwich, and Samoan Islands, and from most of these places have gathered numerous converts. In 1849 the Perpetual Emigration Fund was established, to assist poor Saints in distant lands to emigrate to Utah. Annual and semi-annual general conferences of the whole church are held, generally at Salt Lake City, and quarterly conferences in the various 'stakes,' and usually in the various missionary fields.

Organisation.—The ecclesiastical authorities of the Church of Jesus Christ of Latter-day Saints comprise two priesthoods—the Melchizedek or High Priesthood, and the Aaronic or Levitical, which is the lesser priesthood. The latter ministers in temporal things, the former in spiritual things, though having general authority and supervision over the whole. Apostles, seventies, high-priests, patriarchs, and elders belong to the Melchizedek priesthood, bishops, priests, teachers, and deacons to the Aaronic. The highest authority in the church is the First Presidency, consisting of the president of the whole church and two counsellors. The presidents have been Joseph Smith, Brigham Young (q.v.), John Taylor (1808–87), Wilford

Woodruff (1807-98), Lorenzo Snow (1818-1901), Joseph F. Smith (1838-1918), Heber J. Grant. The death of the president dissolves the First Presidency, the authority then devolving upon the Twelve Apostles, who nominate his successor, always selecting for the office, since the death of Joseph Smith, the president of the Apostles. The third body is the Seventies, of whom there are one hundred councils (commonly termed quorums), each of seventy members, each council having seven presidents, included in the seventy. The seven presidents of the first council of seventies preside over all the councils of seventies. The duties of the above three bodies are general rather than local. The cities and settlements of the Saints are organised into stakes, each usually covering one county. Each stake has a president, assisted by two counsellors, also a high council of twelve members (who are high-priests), presided over by the president of the stake and his two counsellors. Each stake is divided into several wards, presided over by a bishop and his two counsellors. The high-priests of any stake form a council indefinite in number. A council of elders consists of 96 members; of priests, 48; of teachers, 24; of deacons, 12. An apostle is a special witness to all the world. The Twelve Apostles are a travelling presiding high council, to build up the church and regulate the affairs of the same in all nations, as well as at home, under the direction of the First Presidency, when there is a First Presidency. A seventy's duty is to travel and minister under the direction of the apostles. The special office of a patriarch is to administer patriarchal blessings. Apostles, patriarchs, high-priests, seventies, bishops (if high-priests), and elders can preach, baptise (invariably by immersion), lay on hands for the gift of the Holy Ghost, and minister in various other ordinances of the church. Neither priests, teachers, nor deacons can lay on hands for the gift of the Holy Ghost, but a priest may preach and baptise. Neither a teacher nor a deacon can baptise or administer the sacrament, which all the other officers named may do. The special duty of a teacher is to visit and teach the members in order to promote morality and faithfulness. The special duty of a deacon is to attend to minor temporalities, and to assist the teacher in his duties.

Doctrine.—The articles of faith of the Church of Jesus Christ of Latter-day Saints: 'We believe in God, the Eternal Father, and in his Son, Jesus Christ, and in the Holy Ghost. We believe that men will be punished for their own sins, and not for Adam's transgression. We believe that through the atonement of Christ all mankind may be saved, by obedience to the laws and ordinances of the gospel. We believe that these ordinances are (1) faith in the Lord Jesus Christ; (2) repentance; (3) baptism by immersion for remission of sins; (4) laying on of hands for the gift of the Holy Ghost. We believe that a man must be called of God by "prophecy and by the laying on of hands," by those who are in authority, to preach the gospel and administer in the ordinances thereof. We believe in the same organisation that existed in the primitive church—viz. apostles, prophets, pastors, teachers, evangelists, &c. We believe in the gifts of tongues, prophecy, revelation, visions, healings, interpretation of tongues, &c. We believe the Bible to be the word of God, as far as it is translated correctly; we also believe the *Book of Mormon* to be the word of God. We believe all that God has revealed, all that he does now reveal, and we believe that he will yet reveal many great and important things pertaining to the kingdom of God. We believe in the literal gathering of Israel and in the restoration of the ten tribes; that Zion will be built upon this [American] continent; that Christ

will reign personally upon the earth, and that the earth will be renewed and will reach its paradisaic glory. We claim the privilege of worshipping Almighty God according to the dictates of our own conscience, and allow all men the same privilege, let them worship how, where, or what they may. We believe in being subject to kings, presidents, rulers, and magistrates, in obeying, honouring, and sustaining the law. We believe in being honest, true, chaste, benevolent, virtuous, and in doing good to all men; indeed, we follow the admonition of Paul—"We believe all things, we hope all things," we have endured many things, and hope to be able to endure all things. If there is anything virtuous, lovely, or of good report or praiseworthy, we seek after these things' (Joseph Smith).

They also believed in the patriarchal order of marriage, as practised by Abraham, Jacob, and other ancient worthies; they held that it is right and proper, under certain restrictions, for a man to have more than one wife, providing he is chaste and upright in his conduct and otherwise worthy of the privilege. Their marriages are 'for time and all eternity,' as they believe in the perpetuation of the family relationships hereafter. Joseph Smith received the 'revelation on the eternity of the marriage covenant, including plurality of wives,' July 12, 1843, but it was not published to the world until August 29, 1852. A woman, among the Mormons, who does not marry and bear children is regarded as not having fulfilled all the law of her own being. A defence of the system has been set up on moral grounds, as well as on the ground of revelation. They declare that prior to the advent of the Pacific railroads (which, by the way, the Mormons helped to construct), and the consequent influx of 'Gentile' civilisation, their community was free from the horrible vices and degrading social evils that prevail elsewhere; fornication and adultery were unknown; there were no prostitutes, no vile seducers, no illegitimate children. Their wives are asserted to be happy, virtuous, and healthy, and their social and domestic purity and felicity challenge the highest commendation.

Congress has legislated repeatedly against the polygamic feature of their faith. An anti-polygamy law, passed in 1862, remained practically a dead letter, only one conviction being secured in twenty years, and that in a test case, upon evidence furnished by the defendant. For years after the passing of the act referred to congress permitted a Mormon delegate, who had several wives, to hold his seat in the House of Representatives; but in 1882 he was denied that right, and a monogamic Mormon was sent in his stead to congress. In March 1882 an act supplementing the law of 1862 was passed, making it an offence punishable by fine and imprisonment for a man to marry more than one wife or to cohabit with more than one woman. This act, popularly known as the Edmunds Law, was applied specially against the Mormons, and was rigorously enforced. In July 1887 a constitutional convention, composed entirely of monogamic Mormons, who were vastly in the majority in the church, met at Salt Lake City, and, adopting a constitution for the 'state of Utah,' containing a clause prohibiting and punishing polygamy and unlawful cohabitation, applied once more—the fifth time in the history of the territory—for admission to the Union as a state. Like all the previous applications, however, this was refused. Finally, in September 1890 President Woodruff issued a proclamation declaring that the church no longer teaches the doctrine of polygamy or plural marriages, and accepts the United States law prohibiting such marriages; and this declaration was afterwards confirmed in conference. Fol-

lowing the manifesto by President Woodruff, the Mormons began to divide on political party lines, and to fall into one or other of the two great national parties of the republic. The elections which ensued clearly demonstrated that the Mormon people were about equally divided in their political views and preferences. At the session of the United States Congress for 1893-94 the question of statehood for Utah was early sprung, and an Enabling Act for its admission was passed with but little opposition. In accordance with this act a constitutional convention was held in Salt Lake City, the capital of Utah, in March-May 1895, and a constitution framed for submission to the legal voters of the territory. The chief provisions of the Enabling Act were that perfect toleration of religious sentiment should be secured, that polygamous or plural marriages should be forever prohibited, that provision should be made for the establishment and maintenance of a system of public schools which should be open to all the children of said state and free from sectarian control, and that these provisions should be rendered by ordinance irrevocable without the consent of the United States and the people of the state. The constitution as framed was ratified by a large majority. See UTAH. [The foregoing article was written from the Mormon point of view by the historiographer of the church.]

The Reorganised Church of Jesus Christ of Latter-day Saints was formed by those members of the Mormon body who refused to endorse the claims of Brigham Young and other aspirants to the office of president after the death of Smith. They met in conference in 1852 and avowed their allegiance to the original tenets and practices, and repudiated Young and other secessionist bodies. They hold that the *Book of Mormon* is emphatically opposed to the practice of polygamy and condemns it as 'a gross crime,' and that all Joseph Smith's writings and public utterances were strictly opposed to such immorality and in advocacy of monogamy. They deny that Smith was responsible for the 'revelation' on polygamy, and hold that Brigham Young was the sole author of it. There are many other points on which they claim that the Mormon body have departed from the law of the church as contained in the *Book of Doctrine and Covenants*. The Reorganised Church has always been strictly monogamic in faith and practice as in the days of its inception by Joseph Smith. From 1860 Joseph Smith (1832-1914), son of the founder, was their president; and his son Frederick M. Smith (b. 1874) succeeded him. Their headquarters are in Lamoni, Iowa, and Independence, Mo.

The *Book of Mormon* has been translated into several foreign languages, as also the *Doctrine and Covenants*, the *Hymn-book*, and the *Voice of Warning*. Other Mormon publications are *Life of Joseph Smith*, *Life of Brigham Young*, *Key to Theology*, *Spencer's Letters*, *Doctrines of the Gospel*, *Life of Heber C. Kimball*, *Autobiography of Parley P. Pratt*, *Story of the Book of Mormon*, *Snow's Poems*, *Harp of Zion*, and *Correspondence of Palestine Tourists*. Besides the official Mormon literature, see Bancroft's *History of Utah* (1889); Joseph Smith (third) and Heman C. Smith, *History of the Church of Jesus Christ of Latter-day Saints* (from the standpoint of the Reorganised Church; Lamoni, Iowa, 1901); the *Utah Commission* in U.S. Government Reports; books by J. W. Riley (1902), R. and R. W. Kauffman (1912), Cannon and Knapp (1913), Martin (1920), Erickson (1923), and Linn (1924).

Morning Glory. See CONVULVULUS.

Mornington, a hamlet 3 miles E. of Drogheda in County Meath, gave a baron's title to Richard Colley (1690-1758), who, on inheriting a cousin's estate, assumed the name of Wesley or Wellesley, and was created Baron Mornington in 1747. His

son, Garrett Wesley or Wellesley (1735-81), became successively Viscount Wellesley and (1760) Earl of Mornington, and was known as a composer of glees. His son, the second earl (1760-1842), is better known (after 1799) as the famous Marquis of Wellesley.

Morny, CHARLES AUGUSTE LOUIS JOSEPH, DUC DE (1811-65), was by his contemporaries believed to have been the illegitimate son of Queen Hortense and of the Comte de Flahault, and consequently half-brother of Louis Napoleon. He was born in Paris, 23d October 1811, and adopted by the Comte de Morny. He served in the army in Algeria, but in 1838 made his début as a manufacturer of beetroot sugar and plunged into commercial and financial speculation. Chosen a deputy in 1842, he after the revolution of 1848 became the leader of the policy of the Élysée, took a prominent part in the *coup d'état*, and became Minister of the Interior. As president of the Corps Législatif he succeeded in reducing it to subservience, and in 1856-57 was ambassador to Russia, where he married the Princess Trubetzkoi. Created a duke, he maintained a gay and extravagant life till his death. See Imbert de Saint Armand, *The Court of Napoleon III.* (trans. 1890); Loliée, *Frère d'empereur* (1909).

Morocco, or MAROCCO, known to the natives as *Maghreb-el-Aksa*, 'the farthest west,' is an empire or sultanate which, though at one time comprising a portion of Algeria in one direction, and exercising in the other a modified jurisdiction as far as Timbuktú, is now confined to that part of north-west Africa bounded on the E. by the Wad Gir, which separates it from Algeria, and on the S. by Cape Nun and the Wad Draa, which separates it from Río de Oro (Spanish) and French Sahara. As the most powerful of the Sharifs or descendants of Mohammed, the sultan is Prince of the True Believers. Very little of the country has been even roughly surveyed; but, according to the vague knowledge possessed, it contains about 230,000 sq. m., of which the 'Tell' or fertile region west of the Atlas contains 78,000, the Steppes or flat sterile upland pastures 27,000, and the Desert or Sahara the remainder. Politically, Morocco comprises at present the old kingdoms of Fez and Morocco and the territories of Taflet (Tafilalet) and Sus. Since 1912 it has been divided into three zones—Tangier in the north (neutral; 140 sq. m.), a small Spanish protectorate along the Mediterranean coast, and a large French protectorate. Spain also holds a number of settlements on the north coast, and Ifni in the west. There are many provinces or 'amalat,' each presided over by a Kaid, who again has under him various minor officials directing the affairs of the smaller districts, until the head-man of the village is reached. Many of the Arab and most of the mountain tribes are practically independent, never being troubled by the Sharifian officers, and paying taxes when compelled. Over the whole, living in a few moderate-sized towns, and numerous little stationary villages of stone or clay (*dshars*) or in the tent hamlets (*douars*) of wandering tribes, is scattered a population estimated at six millions (5,400,000 in French Morocco). But there is no complete census, and the country-people, in order to avoid extortion and the 'mouna,' or gift of provisions to favoured travellers, prefer to live in retired spots at a distance from the ordinary routes through the country. Morocco is, as a rule, mountainous, the Atlas (q.v.) traversing it in several chains from south-west to north-east, and by various spurs both to the coast country and to the desert. There are, however, numerous level plains, some of which are of great extent, and very

rich, the soil being in many places a deep, black loam, evidently the bed of an ancient lake or of a primeval forest. There are also numerous more or less level plateaus similar to those of Algeria. But with the exception of parts of the Atlas, the forest of Mamora, the date and argan groves of the south, and a few straggling copses around the burial-places of saints, Morocco has, in the course of the last thousand years, been almost denuded of timber, the palmetto (*Chamerops humilis*) scrub being about the most common representative of woodland. Consequently the country looks bald, rolling hills and monotonous plains, green in spring, brown during summer and autumn, being the most characteristic features of the north, though some of the glens and mountain-regions are extremely picturesque. Farther south, and on the other side of the Atlas, where long droughts, followed by famines, are common calamities, and the rainfall is at the best of times scanty and uncertain, sandy wastes are the prevailing characteristic; but in western Morocco, though the soil is sometimes thin and out of the river-valleys stony, actual desert is rare, and, except where the sand has been drifted inland by the winds, not unfitted for pasturage.

The central range of the Atlas forms the watershed separating the streams which flow into the Atlantic and Mediterranean from those which run southward toward the desert, where they are often lost in marshy 'sinks' or *sebkhas*. And of the streams falling into the Atlantic and Mediterranean, many are in the hot season or after long droughts little better than a succession of pools connected by threads of water, though rolling in brown floods from bank to bank during the wet season, when they are dangerous to cross. None of them are navigable for any distance from their mouths, which are always impeded by bars and shoals. Yet before the 14th century vessels of considerable tonnage went 40 miles up the Sus to Tarudant, and stern-wheel steamers could even yet easily navigate the Sebu to within a few hours of Fez. But there are not even barges on them.

The climate of Morocco varies much, though the western slope, being tempered by the sea-breezes and protected from the hot desert-winds by the Atlas, is temperate, the thermometer seldom falling below 40° or rising above 90°. But in summer the interior valleys are very hot, and in winter snow often falls in Fez and Mequinez, where ice an inch thick is by no means uncommon. In Tangier there has been a slight snow-shower about twice in forty years, and in Mazagan even less frequently. Farther south extremes of heat and drought are more common, though as a rule the climate is equable, and, unless in swampy places during summer, extremely healthy. In the Sus country and the region of Tafilet rain is scarce and in places almost unknown. But farther north, and on the Atlantic and Mediterranean slopes, it falls with tolerable regularity every year between October and April, the amount being at times so great that the low lands are flooded, the rivers impassable, and the mountain-sides, unprotected by wood, furrowed by torrents, sweeping the soil and debris before them into the valleys below. On the upper reaches of the Atlas there is all summer a June-like atmosphere; but in winter they are capped deep with snow.

Morocco is thus fitted for growing any crops of the temperate and tropical zones, and, as roads and railways grow, promises to become, as Barbary was in Roman times, the granary of Europe. Barley, wheat, maize, chick-peas, and beans are grown largely, and could be produced in immense quantities. Various gums, oranges, figs, almonds, lemons, and dates are among the other vegetable

products. Cotton and hemp are grown for home consumption. Tobacco cultivation is prohibited and its use forbidden by the sultan, though both it and 'keef' (Indian hemp) are used, as are also alcoholic beverages. Most European fruits grow well, and among other products sugar has been raised. The exports are grain, eggs, linseed, wool, hides, chick-peas, olive-oil, almonds, dates, fowls, bones, esparto, and cattle. The interior of the country is so little known, and the Atlas so entirely unexplored, except hastily in isolated places, that little can be said with certainty regarding its mineral wealth. But enough has been ascertained to enable us to assert that gold (placer and in quartz), copper, tin, argentiferous galena, nickel, antimony, iron, sulphur, and manganese abound. Coal and petroleum have been indicated. Rich silver lodes exist at Gondofi near the head-waters of the Sus, and rock-salt is mined near Fez. But these mineral deposits are scarcely touched. Phosphates, however, are worked inland from Casablanca.

The flora of Morocco is essentially European, so far as the western side of the Atlas is concerned, that of the Atlas generally being a southern extension of the temperate flora of the adjoining continent, with little or no admixture of southern types.

The fauna partakes of a similar character, the Barbary fallow-deer, wild boar, Barbary monkey (found also in Gibraltar), a species of porcupine, and wild cat being the most characteristic mammals; but the lion, once common, is now very rare in the inhabited parts of the country. The birds and fishes are those of southern Europe; the reptiles and amphibia agree better with Spain than the Ethiopian region—facts all pointing to a time when the Strait of Gibraltar did not divide Europe from Africa. Ostriches are seen only in the extreme south. Locusts often devastate the country. The Barbary horses have sadly deteriorated; while in agriculture, oxen, donkeys, camels, and even women yoked with them, are commonly employed to drag the rude one-stilted plough and the harrow, which consists of a bunch of thorns.

The inhabitants consist of six principal groups. The (1) Berbers (*Braber*) or Kabyles, of whom the Amazigh, Shelluh, and Tuareg are only branches, are the aborigines. They inhabit for the most part the mountain regions, and are still only half-subdued. (2) The Arabs are descendants of the 7th-century invaders and later comers. (3) The Jews were very early settlers, semi-independent colonies still subsisting in the Atlas and the Sus country, though most of them in the towns are refugees driven out of Spain and Portugal. (4) Europeans, chiefly French and Spanish, mainly in the coast towns. (5) The 'Moors,' a term vaguely applied to all the Mohammedan inhabitants, are really Arabs with a large admixture of Berber and of Spanish and other European blood. The name is sometimes restricted to the inhabitants of the cities. (6) The Negroes, of whom there are large numbers, were brought from the Sudan as slaves. Most of the latter are still in this condition, though the descendants of some of them now occupy high places in the army and the government. The Jews, though sorely oppressed in the past, prosper amazingly.

The sultan was absolute head of state and church. Since 1912, however, he and his grand vizier have been under the control, in the French zone, of a French resident-general and French ministers; while in the Spanish zone a Spanish high commissioner controls the khalifa, who is chosen by the sultan from two candidates nominated by Spain. It was agreed that Tangier should be an international zone—an arrangement given effect to in 1923-24.

There is a railway from Ujda on the Algerian border to Fez, Mequinez, Rabat, Casablanca, and Marrakesh, with which Tangier is to be connected. Another line runs from Tetuan to Ceuta. Much road-making has been done by the French. The chief industry besides the rude agriculture of the Berbers and Arabs, and the breeding of horses and mules, is the making of 'morocco' leather, harness, slippers, red 'Fez' caps, cloth for native apparel, the chiselling of brass trays, the making of rough pottery and of inlaid flint-lock muskets, and the weaving of carpets (principally in Rabat). The best mechanics and the jewellers are Jews.

Morocco has four capitals or imperial residences, at which the sultan resides at uncertain intervals and for indeterminate periods. These are Fez; Miknas (q.v.) or Mequinez; Marrakesh, better known as the City of Morocco; and Rabat (with Salli, on the opposite side of the mouth of the Bu-Kegreg River). Beside these the principal coast towns are Tangier; Tetuan, capital of Spanish Morocco, a little way up the Martil River; Larache or El-Arish, Casablanca or Dar-al-Baida, Mazagan, Saffi, and Mogador (see separate articles). But all of them are decaying, most of them in partial ruins, and without any exception filthy, undrained, and insanitary to the last degree. When not mere collections of flat-roofed or thatched huts, of sun-dried bricks, around a *kasbah* or walled fortress, they are congeries of narrow intricate lanes, often covered over with vines or reeds to keep out the sun. These lanes are lined with shops which look like large packing-boxes, with the lids raised as a penthouse and padlocked at night, or else with whitewashed windowless walls, over which here and there rise the square towers of a mosque. But within these is often a pleasant courtyard shaded by oranges and palms and cooled by a fountain, into which open gaily Arabesque-painted rooms, furnished with the rich carpets that constitute the principal furniture of a strictly Moorish house. The sole accommodation for travellers is caravanserais, with a yard for beasts and unfurnished rooms for their owners.

After being for more than four centuries a part of the Roman empire, and in the latter period of its sway venerated with a corrupt Christianity, 'Mauritania Tingitana' fell (429 A.D.) into the hands of the Vandals, who held it until 533, when Belisarius having defeated them it became subject once more to the Eastern Empire. But in the year 680 the Arab invasion began, and with little intermission the Arabs have ever since been possessors of the country, and the entire population are now the most fanatical adherents of Mohammedanism. At first, with Spain, part of the khalifate of Bagdad, it became divided into several independent monarchies, and during this period the country enjoyed a prosperity to which it has ever since been a stranger. After seeing the successive dynasties of the Edrisi (789 A.D.), Mahdhiti, Zeiridi, Almoravidi, Almohadi, Beni Marini, Utási, Hosaini, and Filali, and almost unbroken civil and foreign wars and revolutions, the country was united under Muley (Muláí = 'my Lord') Ismail (1692-1727). Morocco, though now more contracted than formerly, has at present, with the exception of the Spanish 'presidios,' no foreign strongholds on its coast, as there were up to the year 1769, when the Portuguese evacuated Mazagan; and from 1859 to 1860, when there was an unsuccessful war with Spain, the country was not disturbed by foreign hostilities till the first of the Spanish-Rif campaigns in 1894. But it is still very backward. A passive resistance was offered to every improvement, though Christian slavery and piracy by government vessels were abolished since 1817-22, and foreign traders have nominally

had access to all parts of the empire. The sultan's disposition to coquet with motor-cars and other European innovations provoked in 1902-3 a serious and widespread rebellion of the orthodox. France proposed a scheme 'for peaceful penetration,' which Britain and Spain agreed to (1904); Germany made difficulty on the ground that it had not been duly consulted; but a European conference at Algieras (1906) arranged a *modus vivendi*: Spain to co-operate with France in organising and drilling a police force for the coast towns and in controlling the Customs. After an anti-European riot in 1907 a French force occupied Casablanca, and in 1909 Spain was again at war in the Rif. In 1909 Germany and France signed an agreement to respect the independence of Morocco. Meanwhile the sultan had been deposed (1907), and his brother, Mulai Hafid, proclaimed sultan. The French interposed again in 1911; and when Germany sent a cruiser to Agadir the relations of Germany with France and Britain were strained, but ultimately Germany agreed to a French protectorate in Morocco. By two treaties of 1912 the French protectorate was accepted by the sultan, and the Spanish protectorate and the neutral zone of Tangier were marked off. Neither of the protecting powers could establish its sway without fighting. Upon Spain especially the burden was very heavy, and the reaction upon home politics was powerful. At Annual in 1921 a great disaster befell Spanish arms, and though Raisuli (or Raisuni) came over definitely to the Spanish side and the dictator Primo de Rivera himself took command (1924), the Rifis under Abd-el-Krim swept the Spaniards down to the coast and turned upon the French. Raisuli was taken prisoner, and died (1925). French and Spaniards meanwhile continued the fight. The French have made roads and railways, built schools, set up new law-courts, reorganised the post-office. The capitulation system has been abandoned. The various towns of Morocco have communication by telephone and telegraph with one another, and by telegraph (wire and wireless) with Europe and Algeria. A Convention in 1923 attempted to provide for the government of the Tangier zone; but settlement lagged and Tangier languished.

See also MOORS, BERBERS, BARBARY.

Morocco, the city. See MARRAKESH.

Morón, a town of Spain, on the Guadaira, 32 miles by rail SE. of Seville; pop. 19,000.

Moroni, GIOVANNI BATTISTA (1525-78), portrait-painter, was born near Bergamo; best known by his 'Tailor' in the National Gallery.

Morpeth, a market-town of Northumberland, on the winding Wansbeck, 16 miles N. of Newcastle. The parish church dates from the 14th century; the free grammar-school, founded by Edward VI. in 1552, was rebuilt in 1859, after a chancery suit lasting 150 years. The town-hall (restored in 1870) was erected in 1714 by Sir John Vanbrugh; the county-hall in 1818. Morpeth

has flannel-factories, breweries, tanneries, iron-foundries, &c., with collieries and quarries in the neighbourhood. From 1553 till 1832 it returned two members to parliament, but now only one; the parliamentary borough now includes Ashington, Bedlington, Blyth. Pop. (1851) 10,011; (1921) 97,117, of whom only 7580 were in the municipal borough.

Morpheus (Gr., 'moulder'), in classic mythology, the son of sleep and the god of dreams. He is so named because he shapes or moulds the dreams that visit the sleeper. He is first mentioned by Ovid, and is represented as an old man with wings, pouring somniferous vapour out of a horn.

Morphine, or MORPHIA, $C_{17}H_{19}NO_3$, was the first alkaloid isolated in a pure state (by Sertürner, an apothecary, in Hanover in 1816). It is the most important of the alkaloids existing in opium, of which it usually constitutes from $\frac{1}{10}$ th to $\frac{1}{6}$ th by weight, and in which it is combined with meconic, sulphuric, and probably other acids. It is obtained as white, silky, translucent crystals, with a bitter taste and alkaline reaction. Morphine is soluble in about 1000 parts of cold and in 400 of boiling water; boiling alcohol dissolves it freely; but it is insoluble in pure ether and chloroform. Morphine is not so easily detected in cases of poisoning by opium as meconic acid (see MECONICUM). The following are some of the ordinary tests for it: concentrated nitric acid added to morphine or any of its salts gives an orange colour; when it is mixed with iodic acid iodine is liberated; in solution it gives a blue colour with persalts of iron.

Morphine is the only opium alkaloid which is soluble in lime-water, and this property affords one of the best means of extracting it. A watery infusion of opium is boiled with milk of lime, filtered, mixed with powdered sal-ammoniac, and again boiled. By this means the lime is converted into the chloride of calcium, the ammonia is volatilised by the heat, while the morphine is precipitated in an impure form, which admits of easy purification.

Morphine combines with acids to form crystallisable salts, which are readily soluble in water and in alcohol. Of these, the hydrochloride, the acetate, the bimeconate, and other salts are much used in medicine. Apomorphine, a white crystalline powder which rapidly causes vomiting, is obtained by heating morphine with an excess of hydrochloric acid.

The therapeutic uses of morphine and its salts are very similar to those of Opium (q.v.), but morphine is employed largely in cases where Hypodermic Injection (q.v.) is desired. The ordinary dose of morphine, or its salts, when given to an adult to allay pain or induce sleep, ranges from an eighth of a grain to half a grain. Many persons are addicted to the habitual use of morphine. The medicinal effects are very much the same as those of opium, and it is taken for the same reasons; but morphine is more rapid in action and more efficacious, and is not accompanied by some inconveniences which attend the use of opium. The habitual abuse has its origin usually in the legitimate use as a medicinal agent. But when the habit is established, the evil consequences soon set in, though some constitutions suffer much more than others. As a rule, *habitués* become pale, sallow, emaciated, appetite is diminished, digestion disordered, sleeplessness sets in, and defies extra doses of the drug. If, as is usual, the morphine is subcutaneously injected, all parts of the body within reach of the syringe may become one mass of sores, so that it is hard to find a place for a new injection. The will is enfeebled: the man or woman may become a mere morphinomaniac.

Morphology (Gr. *morphē*, 'form'), the study of organic form and structure, the counterpart of physiology, which is concerned with habit and function. The term was introduced by Goethe in 1817 in a famous essay. Morphology includes anatomy (descriptive and comparative) and histology (the study of minute structure), and a great part of palæontology and embryology. It discloses fundamental similarities of structure or 'homologies' (see HOMOLOGY), on which taxonomy or classification is based. It reveals the styles of organic architecture or lines of structural evolution. It seeks to show how one form may be derived from another, and its application to shape and proportions, symmetry and axes, and the like, was called by Haeckel 'promorphology.' Primarily it takes form and structure as given, and describes it, but it is bound to pass into embryology in its inquiry into morphogenesis or differentiation. Primarily it is not concerned with activity, but it cannot be withheld from inquiring into the adaptations of structure to use, or into the deep question of the relation between form and function.

See Haeckel, *Generelle Morphologie* (1866); Spencer, *Principles of Biology* (1864-66); histories of Botany by Sachs and others, of Zoology by Carus and others; His, 'On the Principles of Animal Morphology,' *Proc. Roy. Soc. Edin.* xv. (1888); D'Arcy W. Thompson, *On Growth and Form* (1917); J. Arthur Thomson, *The Science of Life* (1899).

Morphy, PAUL. See CHESSE.

Morris, GOUVERNEUR, born in Morrisania, New York, 31st January 1752, was admitted to the bar in 1771. In 1780 he lost a leg by an accident. Assistant in the finance department 1781-84, in 1787 he took his seat in the convention that framed the United States constitution, and in 1788 sailed for Paris. The greater part of 1791 he spent in England as Washington's agent, and then till 1794 was United States minister to France. Returning to America in 1798, he sat in the senate 1800-3, and died 6th November 1816. See *Memoirs* by Jared Sparks (1832), monograph by Roosevelt (1888), and Morris's *Diary and Letters* (1889).

Morris, SIR LEWIS (1833-1907), was born at Penbryn in Carmarthen, and educated at Sherborne and Jesus College, Oxford. He was called to the bar, practised as a conveyancer from 1861 to 1881, and subsequently devoted himself to local work in Wales in education and politics, but failed (as a Liberal) to gain a Welsh seat in parliament. *Songs of two Worlds* (3 vols. 1872-75) showed taste, grace, craftsmanship, and the influence of Tennyson; *The Epic of Hades* (1876) retold in a sufficiently modern spirit the myths and legends of ancient Greece. These pretty idylls were welcomed with joy by a great public. His critics were willing here, as in his later work, to recognise attractive narrative, metrical skill, clear and sometimes forcible thought, unmistakable talent, but refused to acknowledge evidence of true poetic genius. He afterwards published many other books of verse, besides *The New Rambler* (in prose), articles, and addresses.

Morris, RICHARD, LL.D. (1833-94), Early English and Pali philologist, was born at Bermondsey, in 1871 took Anglican orders, and was head-master of the Masonic School at Wood Green 1875-91.

Morris, THOMAS (1821-1908), 'the Nestor of golf,' was born in St Andrews, and served an apprenticeship as golf-club maker with the celebrated Allan Robertson. He went to Prestwick as green-keeper in 1850, where he several times won the championship belt, and returned to St Andrews as green-keeper in 1864. His son 'Tommy,' who died young in 1875, was the best player of his

time, and carried off the belt by winning it three times in succession.

Morris, WILLIAM, poet, artist, manufacturer, and Socialist, was born on 24th March 1834 at Walthamstow, where his father, a prosperous bill-broker in the City of London, then lived. His early years were spent there and at Woodford, both places on the outskirts of Epping Forest. He was at school at Marlborough from 1848 till 1852, and after a year of private tuition at home entered Exeter College, Oxford, at the beginning of 1853, his intention then being to become a clergyman of the Church of England. At Oxford he formed a close intimacy with a small group of undergraduates, and principally among these with Edward Burne-Jones, his closest friend throughout their joint life. This group, which has become historically famous under the title of the Oxford Brotherhood, was united by ardent enthusiasm and lofty ideals, Morris had gone to Oxford as a zealous Anglo-Catholic, but while there his outlook became rapidly enlarged and secularised. Visits to northern France in 1854 and 1855 deepened his inborn love of the Middle Ages; Carlyle and Ruskin became his masters in thought; and he resolved to pursue (in his own words at the time) 'things I have thought of for the bettering of the world in so far as lies in me' by devoting his life to the service and practice of art. As soon as he took his degree he articulated himself to the architect Street, the leading master of revived English Gothic, and went with him to London a few months later. He had already begun to write poetry, and to practise painting and designing. In London, under the powerful influence of D. G. Rossetti, he gave up the professional study of architecture and devoted himself for a time to poetry and painting. His first volume of poems, *The Defence of Guenevere*, was published in March 1858. A year later he married Miss Jane Burden, and began then to plan a house for himself at Upton, in Kent. The problems raised by this house were what turned him into a manufacturer and decorator. The decorative arts in England were then at their lowest level; and he devoted himself systematically to their reinstatement, which in many cases also meant their rediscovery. Together with several of his Oxford friends and some others, including Madox Brown and Rossetti, he founded in 1861 the firm of Morris, Marshall, Faulkner, and Co. (afterwards Morris and Co.), manufacturers and decorators; its object being to reinstate decoration in all its details as one of the fine arts. This business was at first carried on in Red Lion Square, Bloomsbury, then in larger premises in Queen Square, and afterwards in Oxford Street, with workshops at Merton Abbey in Surrey, where it is still continued under the same name. Its chief products were painted windows, furniture, metal and glass work, painted tiles, cloth and paper wall-hangings, jewellery, embroideries, woven and knotted carpets, printed cottons, silk damasks, and tapestries.

In 1865 Morris returned to London in order to be closer to his work, and soon after resumed his writing of poetry. *The Life and Death of Jason* (1867) and *The Earthly Paradise* (1868-70) placed him among English poets of the first rank. They were followed by the dramatic poem *Love is Enough* (1872) and the great epic of *Sigurd the Volsung and the Fall of the Niblungs* (1876). This was his last complete long poem. A number of his shorter poems, lyrics, ballads, &c. were collected in the volume of *Poems by the Way* (1891). He also made verse renderings of Virgil's *Æneid* (1875) and Homer's *Odyssey* (1887).

During his own lifetime Morris became recognised by common consent as one of the greatest among the great English poets of the Victorian age; and his

poetry still fully retains its freshness, power, and charm. In the volume of 1858, which had to wait long for recognition, he sounded a new note of romance, and though his touch was still uncertain, showed himself a master of haunting melody, of delicate psychological insight, and of power to handle and make beautiful tragic and piteous things. The stories of the *Earthly Paradise* reinstated the long narrative poem in literature, and gave it a fresh flexibility and range. One of these, *The Lovers of Gudrun*, stands apart from the rest in subject and treatment, and is the central, if not the culminating, point of his poetry. Finally, in *Sigurd* he re-embodied, with added beauty and unimpaired grandeur, the great ancient epic of the North. His achievement was thus threefold: to continue the movement imparted to English poetry by Keats; to resume the art of story-telling where it had been perfected and left by Chaucer; and to re-create the epic on a Homeric scale and with the nearest approach made in modern times to the Homeric spirit. Poetry, according to Morris, was not a matter of inspiration (whatever that may mean), but of sound workmanship. His own workmanship is uniformly beautiful, his melodiousness and his mastery of construction are equally marked; and while few great poets lend themselves less to detached quotation, fewer still, if any, excel him in continuous beauty of structure and pattern.

Morris was also in his later years a voluminous prose author. At Oxford he had written several remarkable prose romances which appeared in the *Oxford and Cambridge Magazine* (1856), conducted by him and his friends. This form of literature he resumed after a long interval in *The House of the Wolfings* (in mixed prose and verse, 1889), and continued from 1889 to 1896 in *The Roots of the Mountains*, *The Story of the Glittering Plain*, *The Wood Beyond the World*, *The Well at the World's End*, *The Water of the Wondrous Isles*, and *The Sundering Flood*. About 1879 he began to lecture publicly on the arts and their relation to civilisation and the social fabric; some of these addresses are collected in *Hopes and Fears for Art* (1892), *Signs of Change* (1888), and *Architecture, Industry, and Wealth* (1902), and many others have been published separately. Mention must be made also of his translation from the Icelandic Sagas (in collaboration with Eiríkr Magnússon) and from the Old French.

Morris in earlier life had been a Liberal; but his first active interest in politics was in connection with the Eastern Question Association of 1876. In the years that followed, his political outlook rapidly changed. The process through which his mind passed may be briefly summed up thus: Art being a function of life, real and living art was impossible except where life was organised under sound conditions; the tendency of civilisation, ever since the great industrial revolution, had been to dehumanise life; and the only hope for the future was to reconstitute society on a new basis, and thus open the way for art 'by the people and for the people, a joy to the maker and the user.' He applied his instinct for design to the social fabric, and from an artist and designer he became an active and convinced Socialist. The formal step was taken when he joined the Democratic Federation (afterwards renamed the Social Democratic Federation) in 1883; on the same day he had received the highest honour which his old Oxford college had to bestow by being elected an Honorary Fellow. In it, in the Socialist League which broke off from it in 1885, and afterwards on more or less independent lines, he spent the full energies of his later years. In *A Dream of John Ball* (1888) and *News from Nowhere* (1891), two works which have had an enormous influence, he gave fascinating

pictures of his interpretation of history and his visions of the future. Both originally appeared in the Socialist journal *The Commonwealth*, which he edited for several years; as did also portions of a long narrative poem of unequal but great beauty, *The Pilgrims of Hope*, which he never completed.

Throughout this period, as before, his activity as a craftsman was incessant. There were few among the decorative arts which he did not touch; there were none that he touched into which he did not put new life. He concentrated more particularly, in successive periods, on the arts of weaving, dyeing, and printing; in the last, the Kelmscott Press, started by him in 1890, revolutionised printing as a fine art. It was so called after the country home which he had possessed since 1871, a small and very beautiful 17th-century manor-house at Kelmscott on the upper Thames. He also practised the arts of writing and illumination, and produced manuscripts of a beauty such as had not been known since the Middle Ages. His sense of design and colour was faultless, his industry prodigious, and his swiftness of execution almost incredible. He was endowed by nature with great physical strength and amazing vitality; and he turned from one art to another rapidly and easily, because for him the arts were all threaded on one centre, and were all particular embodiments of Art as a single thing; and that thing was production with imagination and with pleasure, and was the beauty and the joy of life. In the prefatory verses to *The Earthly Paradise* he had called himself 'the idle singer of an empty day,' and the words were often quoted against him. But no singer was ever less idle, no day less empty. He held up before mankind not only the example of a simple and noble life, but the hope and vision of a world which might become an Earthly Paradise, a Kingdom of God realised on earth.

Since his death (3d October 1896) the fame of Morris has become fully established, and his influence is greater now than it ever was in his lifetime. The range of his activity and the versatility of his genius perplexed his contemporaries. The sneers at the 'poet-upholsterer,' and the obloquy which he had to face as a revolutionary Socialist, have given place to a juster estimate of his unique genius, and a recognition of his importance as one of the greatest creative and formative forces of his age, in letters, in art, and in the interpretation and organisation of life.

See *The Life of William Morris*, by J. W. Mackail (1899); *The Books of William Morris*, by H. Buxton Forman (1897); *William Morris, his Art, Writings, and Public Life*, by Aymer Vallance (1897); *William Morris, Socialist-Craftsman*, by Holbrook Jackson (1908); *William Morris, a Critical Study*, by J. Drinkwater (1912); *William Morris: a Study on Personality*, by A. Compton-Rickett (1913). There is a collected uniform edition of Morris's writings, including some previously unpublished, with biographical notes by his daughter.

Morris-dance, a rustic dance, formerly an accompaniment to the May-day games and Whitsun-ales, probably of Moorish origin. Douce conjectures it was introduced into England by John of Gaunt on his return from Spain; but Strutt maintained that the Morisco or Moor dance differed from the morris-dance in England, having been accompanied with castanets or rattles at the end of the fingers, and not with bells attached to various parts of the dress. The principal performers of the morris-dance were Robin Hood, Maid Marian, the hobby-horse, and the Bavarian fool. For its connection with pre-Christian rites, Roman or other, see Frazer, *The Golden Bough*; C. J. Sharp, *Sword Dances of Northern England* (1911); and Sharp, MacIlwaine, and Butterworth,

The Morris Book. See also their *Morris Dance Tunes*.

Morrison, CHARLES, a Renfrew surgeon, born at Greenock, and said to have died in Virginia, in 1753 suggested the electric telegraph.

Morrison, RICHARD JAMES. See ZADKIEL.

Morrison, ROBERT, founder of Protestant missions in China, was born, of Scottish parentage, at Morpeth, 5th January 1782, and in 1807 was sent to Canton by the London Missionary Society. In 1809-14 he translated and printed the New Testament. By 1819, with some help, he had done the same with the Old Testament; and in 1823 he completed his great *Chinese Dictionary*. In 1818 he established an Anglo-Chinese College at Malacca. After a visit to Europe (1824-26) he returned to China. In 1834 he was interpreter to Lord Napier, and he died at Canton, 1st August. He was also author of *Horæ Sinicæ* (1812), *Chinese Grammar* (1815), and *Chinese Miscellany* (1825). See Lives by his widow (1839) and Townsend (1888).

Morris Tubes, invented by Lieutenant Morris, are small-bore tubes constructed to be temporarily fixed inside a rifle barrel and fired with a small bullet and a light charge of powder, so as to be used for firing practice in inside ranges. They are sighted as for long ranges. They are also used with cannon, but are fixed outside the weapon and parallel to the bore.

Morritt, JOHN BACON SAWREY (1772-1843), of Rokeby Park, Yorkshire, traveller, writer on the topography of Troy, and Conservative M.P., is best remembered as Sir Walter Scott's friend. See his *Letters* (1914).

Morse. See WALRUS.

Morse, SAMUEL FINLEY BRESEE, inventor, the eldest son of Rev. Dr Jedidiah Morse, geographer, was born at Charlestown, Mass., 27th April 1791. He graduated at Yale in 1810, went to England to study painting, and in 1813 received a gold medal for his statue, the 'Dying Hercules.' In 1826-42 he was the first president of the National Academy of Design at New York. He studied chemistry and electricity, and on a voyage from Havre to New York in 1832 conceived the idea of a magnetic telegraph, which he exhibited to congress in 1837, and vainly attempted to patent in England. His claims to priority over Wheatstone (q.v.) were the subject of controversy. He struggled on heroically against scanty means until 1843, when congress appropriated 30,000 dollars for an experimental telegraph line between Washington and Baltimore. Morse lived to see his system widely adopted, and honours and rewards were heaped upon him. He died in New York, 1872. See Life by Prime (1875), and his *Letters and Journals*, edited by his son (1915).

Morshansk, a town of Russia, 58 miles N. of Tamboff and 150 W. by N. of Penza, with trade in wheat, hemp-seed, and tallow; pop. 30,000.

Mortality. The subject of general tables of mortality is discussed at INSURANCE. Weekly 'Bills of Mortality,' weekly reports as to christenings and burials, were first prepared by the parish clerks of London about 1592-93, in consequence of the frequent recurrence of the plague, and continued by the company of parish clerks till shortly after the Registration Acts of 1840, being superseded by the Registrar-general's returns. The material for the returns was obtained by persons called 'searchers,' and the system was one of disgraceful inaccuracy and systematic imposition. The area 'within the old bills of mortality' was gradually increased, till in 1726 it extended to 21,587 acres. In 1801 the 'New Tables of Mor-

tality' gave the registration district an area of 30,000 acres. See LONDON.

Mortar, a short and very thick piece of artillery of large calibre, firing a heavy shell at a fixed angle of 45° or thereabouts, so that, especially at sieges, the projectile might strike the object aimed at in a direction more or less vertical. They were superseded by breech-loading rifled mortars or howitzers. See CANNON.

Mortar. See CEMENTS.

Mortgage, in English law, is an actual or executory conveyance of real or personal property, as a security for a payment of a debt or the discharge of some other obligation for which it is given, the security being redeemable on the payment or discharge of such debt or obligation. No particular words or form of conveyance are necessary to constitute a mortgage. Property of every description, which is capable of absolute sale, may, generally speaking, be the subject of a mortgage, either legal or equitable. There are two elements in a mortgage. There is the implied obligation to pay; and there is the security for payment. Incident to every mortgage is the right of the debtor to redeem, a right which is called his 'equity of redemption,' and which continues notwithstanding that the mortgagor fails to pay the debt in accordance with the proviso for redemption. This right arises from the transaction being considered as a mere loan of money secured by a pledge of the estate. The right continues unless and until by judgment for foreclosure—i.e. by a decree which deprives the mortgagor of his right to redeem and transfers the property absolutely to the mortgagee, or by the operation of the limitation of actions (see LIMITATION), the character of creditor is changed for that of owner, or the interest of the mortgagor is destroyed by sale either under the process of the court or of a power in the mortgage incident to the security. But there is no right of foreclosure unless the contract contains a condition upon the breach of which a forfeiture is created. A mortgagee may, as a general rule, enter into possession of the land and draw the rents and profits; or he may sue the mortgagor for payment of the sum due. Further rights may be given him by agreement, and it was formerly usual to stipulate for large powers over the property. The Conveyancing Act of 1881 now regulates the powers exercised by mortgagor and mortgagee respectively, unless in so far as its provisions are excluded by express agreement. An equitable mortgage is effected when an owner of property binds himself by memorandum or otherwise to execute a formal mortgage. A person who deposits the title-deeds of his land with a banker, as security for money advanced, is an equitable mortgagor. Mortgage deeds do not, with certain exceptions, require Registration (q.v.). An owner who has mortgaged obtains not unfrequently further advances on security of a second or third mortgage of the same property; a third mortgagee who buys up the first and gets possession of the title-deeds is permitted to tack the first and third mortgages together; both will have to be paid off before the second. There are also cases in which a mortgagee is permitted to consolidate claims against different properties of the same debtor, requiring him to pay off all or none. Formerly the court did not sanction mortgage investments of trust moneys. But, in later times, this rule was to some extent relaxed, and mortgage investments of trust moneys are, under certain conditions, now authorised by statutory enactment. See on this point the Trustee Act, 1893.

A mortgage of goods is made by means of the deed known as a bill of sale (see BILL). Shares, policies of insurance, and even debts, may be mortgaged

by using the appropriate forms of transfer. In all cases, whatever the nature of the property, the Conveyancing Act enables the mortgagee to obtain a sale of the property if the mortgagor is unable to pay principal and interest. See Coote's *Law of Mortgage* (8th ed., 2 vols. 1912).

In Scotland mortgages are effected by means of a bond and disposition in security (see BOND). Mortgages are a higher and better form of security than in England because of the system of registration of deeds affecting land (see SASINE); and trustees have power to invest in mortgage securities, which are considered as safe as government stock, and less liable to fluctuations of interest. In Scotland it is not the practice to mortgage lands by mere deposit of title-deeds.

In the United States the forms and incidents of a mortgage are regulated by the laws of each state. Except in Louisiana, the English law seems to have been accepted on the basis of American legislation. The Homestead Laws enacted by several states have an important influence on the law of mortgage. See L. A. Jones's treatises on the Law of Mortgages (new ed. 1894-1900).

Mortier, ÉDOUARD ADOLPHE CASIMIR JOSEPH, Duke of Treviso (1768-1835), was born at Cateau-Cambrésis. Entering the army in 1791 he was in 1799 promoted general, and, after the first occupation of Hanover, he was in 1804 included by Napoleon in his first list of marshals of France. He distinguished himself at Ulm and Dürrenstein, and in 1807 he served in the Friedland campaign. He was created Duke of Treviso in 1808, and in 1812-13 commanded the Young Guard. He sided with Napoleon during the Hundred Days, and in consequence was for a time in disgrace, but in 1819 he was readmitted to the Chamber of Peers, and from 1830 to the time of his death at the hands of an anarchist was successively ambassador to St Petersburg and Minister of War.

Mortification, in Scots law, is a term used to denote lands given for charitable or public uses.

Mortification, in Medicine. See GANGRENE, INFLAMMATION.

Mortimer. See EDWARD II. and III.; and for Mortimer's Cross, see HEREFORDSHIRE.

Mortlake, part of Barnes urban district in Surrey, on the south bank of the Thames, 2 miles ENE. of Richmond. From 1619 to 1703 it was famous for its tapestry works; now malting and brewing are the leading industries. The Oxford and Cambridge boat race is rowed from Putney to Mortlake.

Mortmain (Fr. *morte main*) signifies in law the dead hand of a corporation. At an early period (1279) the English parliament took note of the mischief which resulted from the transfer of land to religious corporations; statutes were passed restricting the right of corporations generally to hold land. At the present day a corporation, whether it be a college or a railway company, cannot acquire and dispose of land, except in so far as its charter or act of parliament authorises it to do so. The statutes of mortmain were directed against corporations generally; the so-called Mortmain Act of 1736 was apparently intended to guard against improvident gifts of land by will for charitable purposes. The Mortmain and Charitable Uses Act, 1891, allows land to be left by will; but it must be sold within a year or other period fixed by the High Court or Charity Commissioners. Money given to purchase land, and moneys charged upon land, are within the provisions. Land situated in Scotland, in the colonies, or in foreign countries is not within the policy of the English statutes. In Scotland the common law put a somewhat similar check on deathbed aliena-

tions of land; but this check has been abolished by statute. In the United States the laws of several states limit the amount of real estate which may be held by religious bodies and charitable societies; and the laws of the United States impose a limit in the Territories.

Mortola, LA, a small village between Ventimiglia and Mentone, celebrated for the magnificent botanic garden established by Sir Thomas Hanbury. See *Hortus Mortolensis* (1912), and Voigt, *Naturführer* (1914).

Morton, JAMES DOUGLAS, EARL OF, regent of Scotland, was born in the first quarter of the 16th century, the younger son of Sir George Douglas of Pittendriech, near Edinburgh. In 1553, in right of his wife Elizabeth, daughter of the third Earl of Morton, he succeeded to the title and estates of that earldom. He joined the Reformers in 1557; in 1561 was sworn a privy-councillor; and in 1563 was made Lord High Chancellor. Having borne a foremost part in Rizzio's assassination (1566), he fled with his associates to England, but, through Bothwell's interest, in eight months obtained his pardon from the queen. He was privy to the design for Darnley's murder, but was purposely absent from Edinburgh on the night of the tragedy (1567); and, on Bothwell's abduction of Mary, he joined the confederacy of the nobles against them. He figured prominently at Carberry Hill; discovered the 'Casket Letters'; led the van at Langside (1568); and, after the brief regencies of Moray, Lennox, and Mar, in November 1572 was himself elected regent. His whole policy was directed in favour of Elizabeth, from whom in 1571 he was receiving bribes; and his high-handed treatment alike of the nobles and of the Presbyterian clergy, his attempts to restore episcopacy, and the avarice and rapacity imputed to him, daily swelled the number of his enemies, who already included all Mary's adherents. He seemed to have retrieved his temporary downfall by the seizure two months later of Stirling Castle (May 1578); but Esme Stuart in 1580 completely supplanted him in young King James's favour; and on 2d June 1581, as 'art and part' in Darnley's murder, he was beheaded with his own 'Maiden' in the Edinburgh Grassmarket. 'He died proudly, said his enemies, and Roman-like, as he had lived; constantly, humbly, and Christian-like, said the pastors who were beholders.'

See DOUGLAS, MARY QUEEN OF SCOTS, and JAMES VI., with works there cited; also T. F. Henderson's article in vol. xv. of the *Dict. of Nat. Biog.* (1888).

Morton, JOHN, Cardinal, and Archbishop of Canterbury, was born at Milborne St Andrew, in Dorsetshire, about 1420, studied at Cerne Abbey and Balliol College, and practised as advocate in the Court of Arches. Holder of various ecclesiastical preferments and a member of Privy-council, he adhered with great fidelity to Henry VI., yet by Edward IV. was made Master of the Rolls and Bishop of Ely. Richard III. imprisoned him, but he escaped, and joining Henry VII. was by him made Archbishop of Canterbury and chancellor (1486). In 1493 he became a cardinal; and he died 15th September 1500. Sir Thomas More was a page in his house. See Hook's *Lives of the Archbishops*, and *Life of Morton* by Woodhouse (1895).

Morton, LEVI PARSONS (1824-1920), was born at Shoreham, Vermont, was first a country store-keeper's assistant, then partner in a Boston firm of merchants, and in 1863 founded banking-houses in New York and London. In 1878 and 1880 he was returned to congress as a Republican; in 1881-85 he was minister to France; and in 1888-93 he was vice-president of the United States, in 1895-96 governor of New York State.

Morton, SAMUEL GEORGE, an American physician, born in Philadelphia, 26th January 1799, studied medicine there and at Edinburgh, and in 1839 was appointed professor of Anatomy in the Pennsylvania Medical College. He died 15th May 1851. His great works are *Crania Americana* (1839) and *Crania Egyptica* (4 vols. 1844); and his collection, preserved at Philadelphia, contains some 1500 skulls—900 of them human.

Morton, THOMAS, dramatist, was born in 1764 in the county of Durham, but, left an orphan, was brought up by an uncle in London. He entered Lincoln's Inn, but soon quitted law for play-writing, and produced *Speed the Plough* (1798, with its invisible 'Mrs Grundy'), *The Blind Girl* (1801). *Town and Country* (1807), *School for Grown Children* (1826), &c. For thirty-five years he lived at Pangbourne, near Reading, till in 1828 he removed to London, where he died, 28th March 1838.—His son, JOHN MADISON MORTON, was born in Pangbourne, 3d January 1811. From 1832 to 1840 he held a clerkship in Chelsea Hospital, and between 1835 and 1885 wrote a hundred farces, of which *Box and Cox* (1847) alone is said to have brought him £7000. But the rise of burlesque was his ruin, and in 1881 he became a 'poor brother' of the Charterhouse. He died 19th December 1891.

Morvan, LE, a barren district of France (q.v.), a north-easterly extension of the central plateau, is mainly in the department of Nièvre (q.v.).

Morven, or MORVERN, a thinly-peopled mountainous peninsula of north-west Argyllshire, between Lochs Sunart and Linnhe and the Sound of Mull.

Morwenstow, or MOORWINSTOW, a parish in the extreme north of the Cornish coast, 7 miles N. of Bude. Its church, dedicated to St Morwenna, is mainly of Norman date; R. S. Hawker (q.v.) was its vicar.

Mosaics. Mosaic work (Lat. *opus musivum*) consists of small cubes of diversely coloured marble, glass, or other substances set together so as to produce a geometrical or artistic design. It is principally used for ornamental floors and pavements, and for the permanent artistic decoration of the walls of churches and other public buildings. Among the Romans it was very common, for scarcely have the remains of any ancient Roman villa been discovered without finding in it a mosaic pavement. The pieces vary from a quarter to half an inch in size, and they are carefully bedded in a cement surface set over a prepared concrete foundation. Under the Byzantine empire mosaic became a distinctively Christian art, employed for decorating the walls of churches with figures of the Saviour, apostles, saints; and the remains of such Byzantine art form a link of great importance between the classical and mediæval periods. The Cathedral of St Mark, Venice, is a brilliant example of this form of art. St Sofia in Constantinople has a dome which is a mass of jewel-like mosaic. The art was revived in Italy about the beginning of the 13th century, when it was employed with great effect for the decoration of churches; and since that time it has remained, with many fluctuations, a distinctively Italian pursuit. The cubes of opaque glass for mosaic pictures, technically called *smalts* (Ital. *smalto*), are of all possible varieties of colour, as many as 25,000 shades being prepared. At Mixteco in Mexico a mask and shield (12½ inches, containing 14,000 tesserae) of turquoise mosaic were discovered in 1923. Russia contains many very fine examples of mosaic work. A variety of mosaic is extensively produced in India, having been there introduced by the Frenchman Austin de Bordeaux in the decoration of the famous Taj Mahal at Agra, whence it is distin-

guished as Agra work. The Diwan-i-khas at Delhi is an example of this type of work, and is reckoned the most beautiful room on earth. Mosaic pavements are extensively made of small cubes or tesserae of coloured marbles, and baked clay or terra-cotta similar to the ancient Roman tessellated pavements. A modern example of mosaic work of high excellence may be seen in Westminster Cathedral, London.

See Thomas Morgan, *Romano-British Mosaic Pavements* (1886); Gerspach, *La Mosaïque* (1883); W. J. Furnival, *Leadless Decorations, Tiles, Faience, and Mosaic* (1904); J. P. Vogel, *Tile Mosaics of Lahore* (1923).

Mosailima, **MUSEILIMA**, or **MOSAYLIMA** ('Little Muslim'), one of the most important rivals of Mohammed, belonged to the clan Dûl, a division of the tribe of the Beni Hanifah, of Yemāma, in Nejd. The traditions about his life and age are extremely contradictory and legendary. He claimed a prophetic power equal with Mohammed's, and deceived the people of Yemāma by the supposed miracles he performed. Mohammed hearing of this demanded his submission to Islam. Mosailima's answer was a request that Mohammed should share his power with him. 'From Mosailima, the Apostle of God,' he is said to have written, 'to Mohammed, the Apostle of God. Now let the earth be half mine, and half thine: as for Koreish, they are a people without respect for justice.' Mohammed replied: 'From Mohammed, the Apostle of God, to Mosailima, the liar. The earth is God's: He giveth the same for inheritance unto such of his servants as he pleases: Peace be to him that followeth the true Direction.'

After Mohammed's death, in the 11th year of the Hegira (633 A.D.), it at last came to an open breach between the two rival powers. The Beni Hanifah were in rebellion under their prophet to the number of about 40,000. Abū-Bakr, the khalif, sent Khālid, 'the Sword of God,' with a number of choice troops, to compel Mosailima to submission. Mosailima awaited the enemy upon the sandy plains of 'Akrahā. In the battle, which lasted from morning until the evening, Khālid contrived, with fearful losses of his own forces (1200 killed, beside the wounded, including thirty-nine chief companions of the prophet), to gain the victory. Mosailima fell in the 'Garden of Death,' and his heresy was stamped out. It is extremely difficult to come to any clear notion of Mosailima's real doctrines, as all the accounts that have survived of them come from victorious adversaries. See Sir W. Muir, *Annals of the Early Caliphate* (1883) and *The Caliphate, its Rise, Decline and Fall* (ed. Weir, 1924); Prince Caetani, *Annali dell' Islam* (1905-12).

Mosasaurus, a huge fossil reptile, belonging to the remarkable group of Pythonomorphs or 'sea-serpents,' which suggest both lizards and snakes. The remains of three species have been disinterred from Cretaceous strata. They were aquatic animals, furnished with paddles, and are estimated to have attained a length of as much as 75 feet (see **REPTILES**).

Mosch'eles, **IGNAZ**, pianist and musical composer, born at Prague, 30th May 1794, of Jewish parents, was between 1808 and 1816 the favourite musician and music-master of Vienna. Settling in London in 1825, he taught at the Academy of Music and directed at the Philharmonic Concerts. From 1844 he laboured at the conservatory in Leipzig until his death, 10th March 1870. A brilliant performer on the piano and an able composer, Moscheles ranks high amongst modern writers for the pianoforte. He also edited, in English, Schindler's *Life of Beethoven* (1841). See the *Life* by his wife (Eng. trans. 1873), and his Correspondence with Mendelssohn (Eng. trans. 1888).

Moschus, Greek bucolic poet, usually designated of Syracuse in Sicily; he flourished *circa* 150 B.C., and wrote in a style of almost painfully finished elegance a couple of short epics and minor poems. The lament for Bion is believed not to be his. Moschus's works are generally printed along with those of Theocritus and Bion; and there is a fine prose translation of the three, with an introduction, by Andrew Lang (1889); also an edition with verse translation by A. S. Way (1913).

Moscow, formerly, and again since 1918, the capital of Russia, and always venerated as such by the Russian peasantry, stands on the little river Moskva, a sub-tributary of the Volga, 403 miles by rail S.E. of St Petersburg, 768 E.N.E. of Warsaw, and 967 N.N.E. of Odessa. Its centre is the enclosure called the Kreml or Kremlin ('Citadel'), which is surrounded by walls, crowned by eighteen towers and pierced by five gates. This enclosure is the most sacred spot in all Russia. The stranger equally with the native pilgrim, on entering its Saviour gate (1491), doffs his cap to the holy icon of the Saviour that surmounts it. The most notable of the religious buildings inside the Kremlin are the cathedral of the Assumption, built originally in 1326 and rebuilt in 1475-79; its interior is encrusted with mosaics and jewelled ornaments, adorned with venerated pictures, and sanctified by numerous relics of saints; within its walls the early tsars and all the Russian metropolitans and patriarchs have been consecrated, and the metropolitans buried. The cathedral of the Archangel was originally built in 1333, but restored in 1505; here were buried the Russian tsars down to Ivan Alexievich, brother of Peter the Great. The cathedral of the Annunciation, where the tsars were christened and married, shelters some remarkable paintings by Rublev (1405). There are numerous churches of minor rank, and several monasteries; in the Voznesenski monastery (1393) the tsaritsas and female relatives of the tsars were buried. In 1600 Boris Godunov built in the Kremlin the Ivan Veliki tower, 270 feet high, the summit of which commands a magnificent view of Moscow, with her gilded cupolas and fantastic towers, her half Asiatic, half European architecture. Close by, at its foot, stands the gigantic bell, Tsar Kolokol ('king of bells'; see **BELL**). The more important secular buildings within this sanctuary of Moscow are the former imperial palace (1849); containing a museum of great importance; the palace built in the reign of Ivan III.; the Orushenaya palace, which serves as a museum of the most valuable Russian antiquities; the palace of the patriarchs, with archæological treasures and modern Russian and Greek MSS.; the arsenal (1701-36), before which is the trophy of 1812, a pile of 800 or 900 French cannon; and the Hall of the Synod, with a valuable library and ecclesiastical collections. Outside the Kreml the chief objects of interest are the colossal 'Temple of the Saviour' (1838-81), a building commemorative of 1812; the cathedral of St Basil (1554), a 'nightmare in stone,' with fantastic and highly coloured domes and towers, stands at one end of the great Red Square; at the opposite side is the historical museum; while the wall of the Kremlin, under which are the tombs of Lenin and other leaders of the revolution, occupies the third; the library of the synod and its typographical museum; the university (1755), with scientific collections and a library; the public museum (1861) containing a great library; a first-rate ethnological museum, a gallery of pictures, and scientific collections; the Goltzyn Museum (1865), with a library and a collection of paintings; an observatory; a large foundling hospital (1764); and numerous monasteries and special educational institutions. Many of the former palaces became

museums under Soviet rule. A 'popular university' was founded in 1908. Moscow is celebrated for its excellent scientific societies. The suburbs of the city are thickly sprinkled with palaces, parks, and monasteries, some of the first and last being of great historic significance.

Moscow is normally a busy industrial city, manufacturing cotton and woollen goods, silks, iron, leather, tobacco, candles, metallic articles, machinery, paper, chemicals, bricks, carriages, pottery, and watches, all on an extensive scale. There are also a number of large aniline dye-works and platinum-refining factories. But the city occupies an even higher position as a commercial mart. Situated nearly in the centre of European Russia, midway between the Baltic, the Black Sea, and the Caspian, it is one of the

Cathedral of St Basil, Moscow.

principal meeting-places of the streams of Asiatic and European commerce. In the 14th, and more especially the 15th century, it was of even greater importance than it is to-day as a commercial mart. An enormous trade is done in grain, collected from the provinces and exported through the Baltic ports; in timber, from the northern governments; in furs, hides, tallow, and cattle; in the mineral products of the Ural region; in tea, sugar, and other groceries; in cotton, silk, and woollen goods, and in all the various manufactured wares of Russia. Pop. (1864) 365,000; (1897) 988,614; (1915) 1,817,100; (1919) about 1,121,000; (1925) about 1,772,000. The temperature ranges from a winter mean of 14° F. to a summer mean of 66°, the annual mean being 40°.

Previous to its settlement by Great Russians in the 12th century the site had been occupied by Finnish races. The young state was greatly imperilled in its first years by the Mongols, who sacked the town in 1237 and 1293. But by the beginning of the 14th century its princes had secured their position, and began to make conquests and annexations on all sides. In 1325 the metropolitan of central Russia moved his seat to Moscow; a few years later the principality of Vladimir was united to that of Moscow; the Kremlin, built in 1300, was in 1367 encircled with stone walls. Moscow continued to grow in area

and in political influence, and Ivan III. (1462-1505) assumed the title Tsar of all Russia. Its prosperity received serious checks in the next century: it was nearly wholly burned to the ground in 1547, was taken and burned by the Khan of the Crimea in 1571, was hard pressed by the Mongols in 1591, and was the scene of riots arising out of the behaviour of the large Polish retinue who accompanied the bride of the Tsar Demetrius early in the 17th century. During the whole of that century the people frequently rose against the tsars and their unworthy favourites. In 1713 Peter the Great founded St Petersburg (Petrograd, Leningrad) and made it his capital; but the old merchant families, the old conservative nobles, and the common peasantry still continued to look upon 'Moscow the Holy' as the real capital of the empire. The city again suffered greatly from fires in 1739, 1748, and 1753, and the cup of misfortune was filled to the brim when it was set on fire and burned in 1812, according to the traditional belief the patriotic act of its own inhabitants to save it from Napoleon and the French (see NAPOLEON). In the revolutions, though the Kremlin was bombarded, Moscow's art treasures were apparently unhurt, the Treasury of the Patriarchs being almost the only building pillaged. The Soviet Government left St Petersburg for Moscow in March 1918. St Petersburg, depending upon adventitious circumstances, thereafter decayed, while Moscow grew rapidly in population. Great building schemes were taken in hand. Ancient monuments were cleared of later accretions and impertinences, and works of art were put in careful and competent hands. See books by Wirt Gerrare (1900), De Haenen and Grove (1912), Sir Martin Conway, *Art Treasures in Soviet Russia* (1925). The government of Moscow has an area of 12,555 sq. m., and a pop. of 4,000,000.

Moseley, HENRY GWYN JEFFREYS, born in 1887, son of an Oxford professor, was educated at Eton and Trinity College, Oxford. After lecturing for a time at Manchester, he devoted himself to research, showing by the use of X-ray spectra the number and order of the elements ('atomic numbers'). He was killed in 1915 on military service in Gallipoli. See MATTER, PHYSICAL CHEMISTRY.

Moselle (Ger. *Mosel*), a left-hand affluent of the Rhine, rises at the south-west extremity of the Vosges Mountains in France, at an elevation of about 2412 feet. Its course is north-westerly as far as Toul, passing Épinal on the way; thence it proceeds in a north-easterly direction (latterly, with many zigzag picturesque windings) bordering Luxembourg and crossing Rheinland, and joins the Rhine at Coblenz, flowing on its way through Metz, Thionville, and Trier. Its entire length is 315 miles, and it is navigable up to Frouard, 214 miles from Coblenz. Its principal tributaries are the Meurthe, Seille, and Saar on the right, and the Orne, Sure, and Kyll on the left. The wines grown in the basin of the Moselle are noted for their lightness and their delicate aromatic flavour.

Moselle was formerly a frontier department in the north-east of France, but the greater part of it was taken by Germany after the war of 1870-1871, and became as of old part of Lorraine. The small portion left to France was joined to the department of Meurthe. See MEURTHE-ET-MOSELLE. Lorraine, annexed to France in 1919, was made the department of Moselle (2036 sq. m.; pop. 503,810).

Moses (Heb. *Môsheh*; LXX. and Vulgate, *Môyses*), the great lawgiver and judge, under whose leadership Israel first began to be a nation. The whole subsequent course of Hebrew history and literature bears witness to the greatness of his fame

and influence; but the details of his life preserved in that literature, though sometimes very minute, are not, as a whole, very full or satisfying. This was felt to be the case even when it was believed that the so-called 'Books of Moses' were written by him, and, therefore, so far autobiographical; and now that the Pentateuch (q.v.), or rather Hexateuch, is held not to have taken its present form till at least 800 years after his death, and the historical traditions which it embodies are seen to be of various dates and to represent various phases of growth, the outline of his life and character has become dimmer than ever. He still remains, nevertheless, a great historical figure. If we adopt the now very generally accepted belief that Menepthah or Merenptah was the Pharaoh of the Exodus (see EGYPT), Moses was born in the first half of the 14th century B.C. At the time of his birth the 'children of Israel' (*B'ne Israel*) were a pastoral people who had long dwelt on the eastern fringe of the Nile delta, where it begins to merge into the Arabian desert. His name—for which a Hebrew interpretation ('drawn'; the verb is the same as in Psalms, lviii. 16 [17]) is offered in Exodus, ii. 10—is now generally agreed to be really of Egyptian origin (*mosi*, 'born [of]'; cf. *Thutmosi*, Thotmes, &c.). His life divides itself into three periods of forty years each (a definite for an indefinite number), during two of which he had long and intimate experience, first of the civilised life of Egypt, and afterwards of the simple nomadic life of the desert. Ultimately he became the acknowledged leader of Israel in the movement for civil and religious freedom which led to the Exodus. Thenceforward the scenes of his activity were principally Sinai, 'the Olympus of the Hebrew peoples,' En-Mishpat or Kadesh (Gen. xiv. 7), a locality of which the site is not certainly known, and the plains of Moab to the east of Jordan. The greater part of the time was apparently passed at Kadesh, which seems to have long been the national headquarters. Here his energy and force of character, combined with a conciliatory meekness (Numb. xii. 3) which has become proverbial, enabled him to establish the beginnings of the national organisation on an enduring basis. At the foundation of the commonwealth as outlined by him lay the theocratic idea, and the faith which had for its formula 'Jehovah is the God of Israel, and Israel is the people of Jehovah.' Although there is evidence that the name Jehovah was not unknown in pre-Mosaic times, it was not until now that it became a national watchword. Among the religious institutions possessed by Israel may have been some brought by their ancestors in their early migrations from Chaldea, and others that had been more recently acquired in Egypt. To the former class would belong the fundamental institutions of sacrifice, and also, possibly, that of the Sabbath; on the other hand it seems probable that the ideas connected with an ark and a separate priesthood had the later origin. The practices resting on these Moses as a 'prophet' presumably regulated and reformed. It was as a member of the priestly caste (he belonged to the tribe of Levi) that at the sanctuary and oracle of Jehovah at the 'Well of Judgment' (En-Mishpat) he exercised the functions of law-maker and judge, and so laid the foundations of that 'Torah'—i.e. 'instruction' or 'law'—which, after obscure vicissitudes, enriched by ever-broadening precedents, ultimately passed into writing in more than one form as the 'Mosaic legislation.' Irrespective of the question whether writing was much used in these days, practically all critics are agreed that the historical portions, as well as almost all the legislative documents, of the Pentateuch belong to a much later time. The poetical compositions

which are attributed to Moses—the so-called 'Song of Moses' (Deut. xxxii.) and Psalm xc.—also give internal evidence of more recent authorship. See PENTATEUCH.

After the close of the Old Testament canon Jewish tradition still busied itself about the story of Moses; some of its later additions have been preserved in the writings of Philo and Josephus (cf. Acts, vii. 22), and many more in the Palestinian Targum on Exodus. Compare also the references in the Index of Charles's *Apocrypha and Pseudepigrapha*, vol. ii. p. 859 seq. See further the histories of Israel by Ewald, Stanley, Wellhausen, H. P. Smith, &c., and the works dealing with the Pentateuch and with Israelite religion and Jewish theology. For much miscellaneous illustrative material see Gressmann, *Mose und seine Zeit* (1913), and Sir J. G. Frazer, *Folk-lore in the Old Testament* (1918).

Mosheim, JOHANN LORENZ VON (1694–1755), a distinguished church historian of Germany, was born at Lübeck, studied at Kiel, became in 1723 professor of Theology at Helmstedt, in 1747 at Göttingen, as well as Chancellor of the University. His theological works are numerous, but his most important work belonged to the department of church history, his *Institutiones Historiæ Ecclesiasticæ* (1726; improved ed. 1755) being familiar to every student as a work of great learning and accuracy in very elegant Latin. Its author is, in Gibbon's phrase, 'full, rational, correct, and moderate.' Murdock's translation (3 vols. N. Y., 1832) was brought down to his own time by Stubbs (1863).

Moskwa, rises in a marsh in the east of Smolensk, flows east to the city of Moscow, and thence 112 miles south-east to the Oka. Its total course is 305 miles. It is navigable from its mouth to Moscow, except between November and April, when it is generally frozen, and is connected directly with the Volga by the Moskwa Canal. See BORODINO.

Mosque, a Mohammedan house of prayer. The word is derived, through the Italian *moschea*, from the Arabic *mesjid*, 'a place of prayer.' The form of the oldest mosques is evidently from that of the Christian basilica (see ARABIAN ARCHITECTURE). The original forms became, however, entirely obliterated, and the mosques, with their arcaded courts, gateways, domes, and minarets, became the most characteristic edifices of Saracenic art. Wherever the Mohammedan faith prevailed, from Spain to India, beautiful examples of these buildings exist. They vary considerably in style in different countries, the Saracens generally borrowing much from the architecture of the various nations who adopted their faith. In India the mosques have many features in common with the temples of the Jains, while in Turkey they resemble the Byzantine architecture of Constantinople. Everywhere the dome is one of the leading and most beautiful features of the mosques, which commonly consist of porticoes surrounding an open square, in the centre of which is a tank or fountain for ablution. Arabesques and sentences of the Koran inscribed upon the walls, which are generally whitewashed, and never bear any device representing a living thing, are the only ornaments of the interior. The floor is generally covered with mats or carpets; there are no seats. In the south-east is a kind of pulpit (*mimbar*) for the imám; and in the direction in which Mecca lies (the Kibleh) there is a niche (*mihrab*) towards which the faithful are required to look when they pray. Opposite the pulpit there is generally a platform (*dikka*), surrounded by a parapet, with a desk bearing the Koran, from which portions are read to the congregation. The five daily prayers, which are generally said at home on week-days, are said in the mosque by the whole congregation on Fridays and certain other days, together with some additional prayers, and at times a sermon is super-

added to the service. It is not customary for women to visit the mosques, and if they do, they are separated from the male worshippers. On entering the mosque, the Moslem takes off his shoes, performs the necessary ablutions, and finishes by putting his shoes and any arms he may have with him upon the matting before him. The chief officer of a mosque is the nazir, under whom are two imâms, a kind of religious official, who is in no way to be compared with what we understand by a clergyman, but performs a certain number of religious rites, and, being very badly remunerated, generally has to find some other occupation besides. There are further many persons attached to a mosque in a lower capacity, as Muezzins (q.v.), door-keepers, &c., all of whom are paid from the funds of the mosque itself—generally derived from lands. With many of the larger mosques there are schools, academies (medressehs), and hospitals connected, and public kitchens, in which food is prepared for the poor.

Mosquitia. See MOSQUITO COAST. There is also a department of Honduras so named.

Mosquito. See GNAT, MALARIA, YELLOW FEVER.

Mosquito Coast, or MOSQUITIA, now the department of Bluefields, formerly an independent state under the protectorate of Britain, lies on the east side of Nicaragua (q.v.), to which it has belonged since 1860, in absolute sovereignty since 1906. The coast-lands are low and swampy, but the interior rises into mountains, and is healthy. The characteristic products of the West Indies are grown. The inhabitants are a mixed race, of Indian and African blood. The chief town is Bluefields, a banana port. The Mosquito Coast was discovered in 1502 by Columbus, and, though never conquered, was claimed by Spain. During the 17th century it was the rendezvous of the Buccaneers (q.v.), and was subjected to Britain in 1655, who only abandoned it in 1850.

Mossamedes, a seaport on Little Fish Bay, in Angola, with fishing and fish industries; pop. 3500.

Mossel Bay. See ALIWAL.

Mosses (Musci). The mosses are a class of small flowerless plants, important in the economy of nature, and of great interest in their life-history. They are found in all climates, but are most abundant in temperate regions and in damp places. They are included with the Liverworts in the division Bryophyta, which is sharply separated from the higher division of Vascular Cryptogams (Ferns, &c.) by the absence of wood vessels; while the lower members of the group, e.g. certain Liverworts, consist of a mere flat thallus, and show affinity to the Thallophytes. This, with other characters, indicates that the Bryophyta form a branch of the tree of evolution of an intermediate type, the mosses being a terminal class.

The uses of mosses in medicine and the arts are few and unimportant, but in mountain-regions the thick felts of moss and deep beds of peat soak up the rain, and so prevent floods from sudden storms, and in dry weather supply the streams through weeks of drought. With favourable surroundings the life of a moss-plant seems to be endless; the mosses (Sphagnum) we see growing to-day in a bog are the tips of plants which began life perhaps thousands of years ago, and which have formed a great bed of peat, which may be 20 feet thick. This social habit of mosses is a peculiarity. In some species cushions of great regularity are formed; this enables individual plants to stand erect, and is important in fertilisation, besides affording mutual protection. The capsules of

many mosses must be familiar to every one as small sacs at the end of their hair-like stalks, which rise in great numbers from a moss-cushion. These contain the spores, from each of which when sown there grows in a few days a tiny thread-like plant, the protonema. Buds of young moss-plants soon appear on this, and then, as a rule, the thread-plant dies. A moss-plant consists of a stem with leaves and roots. The roots will grow out from any part of the plant that is kept dark and damp; they are very like the protonema, indeed buds of

Diagram of the Life-history of a Moss :

a, spore; b, spore producing the thread-like or alga-like protonema; c, bud from protonema which will rise into moss-plant; d, a leaf-bearing portion of moss-plant; e, apex of moss-plant with club-shaped male organs (antheridia) producing male cells, one of which lies between e and f; f, apex of moss-plant with bottle-shaped female organs (archegonia) within which is the female cell; g, g', spore-producing generation which grows from division of fertilised egg-cell and upon female plant.

new plants may arise on them. Even from a detached leaf roots and new plants will grow; this is a sign of the simple nature of the tissues. By their branching habit, and by the death of the older parts, which leave the branches as separate plants, and in many species by special buds or gemmæ which are easily separated from the parent, mosses are rapidly propagated, indeed in many species the production of spores is rare. The sexual mode of reproduction is as follows. At the apex of a plant in the autumn may often be seen what are popularly known as moss flowers. These consist of a rosette of numerous leaves, smaller than ordinary, a sort of bud in fact. In the centre are male and female organs (antheridia and archegonia), but in some species the sex organs are on different plants; within the 'flowers' are also jointed, often club-shaped, hyaline hairs known as paraphyses. The antheridia are club-shaped bodies; when ripe, if wetted, they burst and the contained cells are squeezed out as a gelatinous mass. Within each cell is a small motile spermatozoid, which is able to swim away if the moss is thoroughly wet. The archegonia are flask-shaped; within each lies, in the bottom of the flask, the large egg-cell. The neck is lined with the canal cells, which, when the egg-cell is ready, swell up and form mucilage. If an antherozoid is near, it enters the mucilage, and working down to the egg-cell fertilises it. The ovum now grows within the archegonium, and the developing embryo forces an absorbing organ into the parent plant for nourishment. The archegonium at first swells with the growing embryo, but ultimately splits transversely, its upper part becoming the calyptra of the capsule, and its lower part the vagina of the stalk. The ripe capsule has usually a complex structure; below its calyptra is the operculum, which falling off by movement of the annulus leaves the peristome exposed. The latter is often a complicated organ consisting either of a membrane with a central aperture, or, more frequently, a single or double circle of teeth of

very varied form and size. The peristome teeth being hygroscopic, open or close upon the enlarged top of the central columnella, liberating or retaining the ripe spores according to the atmospheric humidity. Of these spores we have already spoken, and thus the life-cycle of the moss is completed. This cycle consists of two generations, the moss-plant which produces an egg; from the egg grows a plant which produces spores, but itself remains attached to the parent plant. This is called an alternation of generations. The fern has a similar story, but in this case the two generations have a separate existence and the spore-bearing generation is the conspicuous plant. Fossil remains have been found in rocks of Palæozoic age.

Classification.—There are over 3000 species divided into four orders. (1) Bryaceæ, which include the vast majority of genera. The sporangium always has a calyptra, which falls off when ripe; beneath is the operculum which splits off from the capsule exposing the peristome teeth. The capsule has a long stalk or seta. Common forms are Hypnum, Funaria, Polytrichum, &c. (2) Phascaceæ, a small order now usually united with the Bryaceæ; the spores are set free by the rotting of the sporangium; the protonema persists until the maturity of the sporangium. (3) Andreaeaceæ, a single genus; no operculum; the sporangium opens by 4-8 longitudinal slits. (4) Sphagnaceæ, bog mosses; some of the cells of the leaves grow larger than the rest, lose their contents while their walls become spirally thickened; these cells open one into the other; the smaller cells are filled with chlorophyll, and form a network round the large water-cells. The tissue of the stem has in the centre a sort of pith; outside this a layer of long cells with thick walls; outside this an epidermal layer of large water-cells. The male and female organs are either on separate branches or separate plants.

See articles LIVERWORTS, FERNS, GENERATIONS (ALTERNATION OF); also Campbell, *Mosses and Ferns*; Hofmeister, *On the Higher Cryptogamia*; Müller, *Musci* (over 1100 pp., very important) in Engler and Prantl, *Pflanzenfamilien*; Limpricht, *Die Laubmoose Deutschlands* (2400 pp.); Goebel, *Outlines of Classification and special Morphology*; Bennet and Murray, *Handbook of Cryptogamic Botany*; and works on British mosses by Wilson, Hooker and Taylor, Berkeley, Dixon, Braithwaite, Stark, Holmes and Gray, Bagnall, and Hobkirk.—The so-called Irish moss (see CARRAGEEN) is a seaweed. Corsican moss and Ceylon moss are names of algæ (of the genus *Plocaria*) used for producing an edible mucilage. Iceland Moss (q.v.) is a lichen.

Most. See BRÜX.

Mostaganem, a town of Algeria, on the coast, 45 miles N.E. of Oran, manufactures pottery, and has corn-mills and tanneries. Pop. 27,000, more than one-third being Europeans. It was a place of 40,000 inhabitants in the 16th century; and has again grown up from its decayed state since the French took possession in 1833.

Mostar, the chief town of Herzegovina, on the Narenta, about 35 miles from the Adriatic, connected by railway with the port of Metković, and *via* Sarajevo with Belgrade, Budapest, and the rest of Europe. It takes its name ('old bridge') from a 16th-century bridge of one arch, 95 feet in span, has numerous mosques, and is the seat of a Roman Catholic and a Greek bishop. Wine is produced, and swords and tobacco manufactured. Pop. 18,000.

Mosul, a decayed town of Mesopotamia, is situated on the right bank of the Tigris, opposite the ruins of ancient Nineveh (q.v.), 200 miles up the river from Bagdad, and on the Bagdad railway. It is partly surrounded by crumbling walls. During the middle ages it was a very prosperous city, with much industry—*muslin* takes name from this

town; now its bazaars are filled with the manufactures of the West, and almost the only export is gall-nuts, from the Kurdish mountains. Mosul was formerly the metropolis of the Mesopotamian Christians (the Nestorians, the Uniat Chaldeans, the Jacobites, &c.), and still contains many Catholic Christians. Pop. about 60,000. The town, which existed in 636, enjoyed its greatest prosperity in the 9th century, and onwards, until the desolating inroads of the Mongols in the 12th. Then came the Seljuks; and they were followed by the Osmanli, and from then Mosul steadily declined, till Mesopotamia was detached from their empire. Whether the town and vilayet of Mosul should remain so detached proved a difficult question, which the League of Nations attempted to solve in 1925. See H. C. Luke, *Mosul and its Minorities* (1925).

Moszkowski, MORITZ, pianist and composer, born 1854 at Breslau, was educated at Dresden, and the Stern and Kullak Conservatories at Berlin. After teaching at Berlin he went to Paris in 1897. He was made a member of Berlin Academy in 1899. His chief works are *Boabdil, der Maurenkönig* (1892), the ballet *Laurin* (1896), *Jeanne d'Arc*, and *Aus aller Herren Landen*.

Motacillidæ. See WAGTAIL.

Motazilites, a 'heretical' Mohammedan sect, founded by Wasil ibn 'Ata in the 2d century after Mohammed. They denied predestination, and recognised in man a power over his own actions.

Mote-hill. See CASTLE. For the very different Moothill (often confused with Mote-hill), see FOLKMOOT.

Motett, a name applied to two different forms of musical composition—(1) a religious cantata, consisting of several unconnected movements, as a solo, trio, chorus, fugue, &c.; (2) a choral composition, generally also of a religious character, beginning with an introduction in the form of a song, perhaps with figurative accompaniment; after which follow several fugue subjects, with their expositions, the whole ending either with the exposition of the last subject, a repetition of the introduction, or a special final subject. A motett differs from a double or triple fugue in that the subjects never appear simultaneously, but are introduced one after the other. In one form of the motett the successive phrases of an entire choral are treated as so many fugal subjects.

Mother Carey's Chicken, a name (a corruption of *Mater cara*) familiarly given by sailors to the Storm Petrel and other small oceanic species of Petrel.—The name MOTHER CAREY'S GOOSE is, in like manner, given to the Giant Petrel or 'Nelly' (*Ossifraga gigantea*) of southern seas (see articles on PETREL and FULMAR).

Mother of Pearl. See PEARL.

Motherwell and Wishaw, a police burgh of Lanarkshire, 12 miles S.E. of Glasgow. Until 1920, when the burghs were amalgamated by mutual consent under Act of Parliament, Motherwell and Wishaw were separate towns, founded in 1865 and 1855 respectively. The new town is entirely industrial, possessing, as it does, important iron and steel works. It has fine public parks. Pop. (1921) 68,869.

Motherwell, WILLIAM, Scottish poet and antiquary, was born in Glasgow, 13th October 1797, and educated in Edinburgh and at the grammar-school of Paisley, where, in his fifteenth year, he entered the office of the sheriff-clerk. At the age of twenty-one he was appointed sheriff-clerk depute of the county of Renfrew. In 1819 he published his first work, the *Harp of Renfrewshire*, containing biographical notices of the poets

of that district from the 16th to the 19th century. This work was but the prelude to one of far greater importance—his *Minstrelsy, Ancient and Modern* (1827). In 1828 he started the *Paisley Magazine*, in which some of his finest original pieces first saw the light, and in the same year accepted the editorship of the *Paisley Advertiser*, a Conservative journal. In 1830 he became editor of the *Glasgow Courier*. In 1832 he published a collection of his best poems, entitled *Poems Narrative and Lyrical*. He died in Glasgow, 1st November 1835, at the early age of thirty-eight. Motherwell displays in his best moods (but only then) a rich, beautiful, and strong imagination, great warmth and tenderness of feeling, and a thorough knowledge of the technique of a poet. His *Jeanie Morrison* is unsurpassed for the mingled pathos and picturesque beauty of its reminiscences of boyish love; and the little piece beginning, 'My heid is like to rend, Willie,' has seldom been read without tears. An enlarged edition of his poetical remains, with a memoir, was published in 1849, and reprinted in 1881.

Motherwort (*Leonurus Cardiaca*), a plant of the family Labiatae, found about hedges and

Motherwort
(*Leonurus cardiaca*)

in waste places in Europe, and now abundantly naturalised in some parts of North America. It is not very common in Britain, and probably has been introduced. It is perennial, has a branched stem about 3 feet high, stalked leaves, the lower ones 3-lobed, and crowded whorls of reddish-white flowers. The plant was formerly in much use as a domestic pectoral medicine, but is now comparatively little employed. It has a strong, but not agreeable smell.—Other species of the same genus are found in Europe and the north of Asia.

Moths (*Heterocera*), a name applied to those Lepidoptera

which are not butterflies (*Rhopalocera*), but the distinction has little scientific value. In moths the antennae are rarely clubbed (as they are in butterflies, except the 'Skippers' or *Hesperiidae*); and there is usually a definite linking structure or frenulum connecting the base of the hind-wings to the fore-wings. Butterflies are as a rule diurnal and moths nocturnal, but many moths fly by day. There are more than forty different families; see **DEATH'S-HEAD MOTH**, **HAWK-MOTH**, **SILK**, &c. Clothes moths belong to the family *Tineidae*, and many to the genus *Tinea*. The small caterpillars mine in cloth, fur, and the like. Badly infested articles should be burned, or exposed to sun and air, or soaked in boiling water, carbolic acid, or petrol solution. Furs carefully wrapped in paper without holes are not attacked. The adult moths may be kept from drawers or wardrobes by using pieces of camphor, naphthalene, or 'moth powder.' See also **BUTTERFLY**, **CATERPILLAR**, **INSECTS**.

Motif, in a musical composition, means the principal subject on which the movement is con-

structed, and which, during the movement, is constantly appearing in one or other of the parts, either complete or modified. In elaborate and long compositions there are also secondary motifs. A leitmotif is a phrase associated with a character or an idea, introduced in the music when the composer wishes the hearer to call the associated subject to mind.

Motion. For the Laws of Motion, see **DYNAMICS**, **FORCE**, **NEWTON**; for Motion in Plants, see **PLANTS**, **INSECTIVOROUS PLANTS**, **SENSITIVE PLANTS**, **SPORE**; for Animal Locomotion, see **FLIGHT OF ANIMALS**, **HORSE**, &c.

Motley, JOHN LOTHROP, was born in Dorchester, Massachusetts, 15th April 1814, and studied at Harvard and several German universities. In 1839 he published an historical novel, *Morton's Hope*; another, *Merrymount*, a protest against the gloom of Puritanism, was better received (1849). In 1841 he went to St Petersburg as secretary of legation, but he disliked the post and the place, and soon resigned. In 1849 he served a term in the Massachusetts legislature; and by this time he was hard at work on what was to prove his first great literary triumph. Fully ten years were spent on his *Rise of the Dutch Republic* (1856), covering the period from the abdication of Charles V. to the assassination of William the Silent (1555-84); and this work established his fame. In 1857 he was once more in Boston, but soon returned to Europe, as the materials for European history were not accessible in the States. The *History of the United Netherlands* appeared in 1860-69; it begins where the *Dutch Republic* broke off, and comes down to the year 1609. His letters to the *Times* on the civil war were probably the most important of all the efforts made by patriotic Americans to enlighten the British public upon the issues involved. In 1861-67 he was minister to Austria, in 1869-70 to Great Britain, being summarily recalled through a feud between Grant and Sumner. His last work was *The Life and Death of John Barneveld*, a biography which is virtually a continuation of his main theme. After his wife's death in 1874 Motley paid another visit to the States; and on his return to England in 1876 he gradually sank, and died at Kingston Russell, the Dorsetshire residence of his son-in-law, Sir William Harcourt, 29th May 1877. Motley is a typical representative of the picturesque school in history. His laborious researches and his vivifying imagination enabled him to make the past live again, and, within certain limits, he was true to his materials; but he glories in being a partisan, though of his desire to be faithful there is no question. His elaborate and eloquent style sometimes attains real splendour, but is apt to fatigue.

See *Memoir* by O. W. Holmes (1878), his Correspondence edited by G. W. Curtis (1888) and by his daughter Mrs Mildmay (1910), short Life by Professor Jameson (1897), and Moncreu Conway's biographical introduction to the 1896 edition of the *Dutch Republic*.

Motor-cars. Cugnot, a Frenchman, constructed a steam-carriage in 1769, in which the motion was transmitted from the steam-cylinders to the driving-axle by ratchet wheel; a street accident put an end to his work. In England Trevithick built a steam-carriage in 1803, which ran successfully and attained a speed of 10 miles per hour. From 1823 to 1836, owing to improved roads, there was a revival of interest in the subject. Gurney in 1828 designed a steam-carriage; his coaches ran for some months in 1831 between Gloucester and Cheltenham. Ogle in 1831, with a carriage able to carry 16 passengers, obtained a speed of 30 miles per hour; and Hancock during the years 1829-36 did some very successful work:

in 1836, for over 20 weeks, his omnibuses kept up a regular service in London. The opposition of those interested in railways, and of the road trustees, strangled this promising new development, and the Locomotive Act of 1836 put an end to all further attempts at automobilism in Great Britain till its repeal in 1896. In France interest in automobilism was again roused, after over a century of rest, by Serpollet, who in 1891 patented a steam-car, using superheated steam; and in 1891 a car with a Daimler petrol motor ran from Paris to Brest. From that date the progress in automobilism has been perhaps the most remarkable development in the field of mechanical engineering.

Steam Cars are now almost negligible, except that wagons for heavy commercial loads have held their own, owing to their cheapness and simplicity. The steam-engine will work at low speeds, and a simple 'link-motion' takes the place of an elaborate gear-box. The boilers are usually of the 'flash' type, in which the water passes through a long coil of tubing, heated by oil-burners, and is converted into superheated steam.

Petrol Cars.—The principle of the petrol-engine is explained in the article INTERNAL-COMBUSTION ENGINE. The fuel is chiefly petrol of about 720 sp. gr.; a mixture of petrol and benzol is often used, while alcohol and other substitutes have been tried. Cooling is effected by a water-jacket (small motors for cycles are air-cooled), the water being circulated either by pump or naturally by changes in density owing to temperature changes. The jacket water is cooled by passing through air-cooled radiators.

The reciprocating motion of the pistons is converted into a rotary motion by the crank-shaft, and owing to the high speed of the internal-combustion engine a fly-wheel is fitted, to maintain an even and smooth running, especially at slow speeds. In order that the engine may run at a suitable high speed while the car is running at widely different speeds or is struggling with a hill or an unusually heavy load, it is necessary to provide a means for varying the gearing by which the road-wheels are driven. It is also necessary to have means of travelling backwards, and a reverse-gear is therefore fitted.

The system almost universally adopted is to connect the crank-shaft to a gear-box containing parallel shafts, upon each of which are toothed gear-wheels which are free to slide along the shafts, but not to revolve round them. By means of selector-levers the different gear ratios are obtained by meshing different combinations of wheels. The top gear is usually a 'direct drive'—i.e. the propeller-shaft leading out of the gear-box is connected directly to the shaft entering the gear-box and revolves at the same speed.

To change gears it is necessary temporarily to disconnect the engine from the shaft leading into the gear-box, and this is done by a clutch. The drive being transmitted by the friction of surfaces held together by a strong spring, release of the pressure disconnects the drive.

In the very early cars the drive was often taken to the axle by a chain or belt, but except in the motor-cycles and cycle-cars this has been discontinued. The usual practice is to take the drive from the gear-box to the centre point of the back axle by means of a 'propeller' or 'cardan' shaft. The back axle is divided in the centre. To the outer end of each half-shaft is fixed the hub of the road-wheel, while the inner end has a bevel pinion working in what is known as the differential gear. This gear compensates for the fact that when the car is travelling in a curve the outside wheel has to cover a longer distance than the inside wheel, and consequently has to travel faster.

Electric Cars.—These are of two classes. In one

the current is derived from storage batteries, and the car can only run until the batteries 'run down.' A few broughams for town use have been made of this type, but the chief adaptation of this principle is for trolleys used in railway stations and in large works for transporting goods at low speeds. Electric-power companies occasionally employ large lorries of this type, finding them cheap to run in view of the facilities for charging the batteries. The other type uses electric power as a device to avoid gear-box transmission. The ordinary internal-combustion engine drives a dynamo, which in turn supplies an electric-motor geared to the road-wheels. One well-known make of heavy chassis for lorries and buses follows this design.

Motor-cycles.—The early motor-cycles were of medium power—3 or 4 horse-power. They had battery ignition, usually only a fixed gear, and a belt-drive. Motor-cycles have now been designed to suit almost every requirement of cost, power, and speed. They range from cheap light machines with engines as low as $1\frac{1}{2}$ h.p. to heavy racing cycles of as high as 10 h.p. Two-stroke engines are used for many of the lighter makes, but four-stroke engines—often with two, and very rarely with four cylinders—are used for the heavier models. Chain-drive is gradually ousting belt-drive, and two, three, and even four-speed gear-boxes with clutch and kick-starter are fitted. Refinements are constantly being made in such matters as sprung frames, mechanical lubrication, and electric-lighting generated by a small dynamo. Sidecars superseded trailers, but are in turn losing their popularity in competition with the very cheap light cars. See also CYCLING.

MOTORING.—Few movements have made such rapid and universal progress as motoring. When the century began it was the pursuit of a comparatively few pioneers in France, with a small vogue in Germany, and a still smaller vogue in the United Kingdom.

The motor-car has reopened many of the highways of Europe and made them once more the arteries—secondary, it is true—of travel and communication, has saved rural districts from depletion and comparative isolation, has quickened the daily life of city and town. The motor taxi-cab has displaced the horsed-cab, the motor-bus has driven the horsed-bus off the road, the railways have suffered, and all despite a natural antipathy on the part of the public to the changes involved. The abridgment of time and space secured by the use of the motor-car in its various forms is but the beginning of a revolution, the end of which no one may yet see. The motor-car made the aeroplane-engine a possibility. The navies of the world, as at present constituted, are threatened with supersession because the motor-car has shown the possibilities of the internal-combustion engine for hitherto unthought-of purposes, and the arts of agriculture and of war are being transformed.

Although to Germany belongs the honour of the inception of the motor-car engine, to France the world owes its rapid development and the practical evolution of the motor-car. It is generally asserted by apologists that the diatribe of Great Britain in adventuring into the new movement was due to the repressive Highways Act of 1865, which restricted mechanical traction on public roads to a speed of 4 miles per hour, and required a man to walk in front with a red flag. This was amended in 1896 as the immediate result of a demonstration of mechanically propelled vehicles organised by Sir David Salomons, and the speed-limit was raised to 14 miles per hour. But not until 1903, when the legal limit was increased to 20 miles per hour, was the British industry really founded. Rapid development in efficiency and power was due to the system of

racing competitions inaugurated by the Automobile Club de France, founded in 1896. In 1894 *Le Petit Journal* had organised the first motor-car road-race—from Paris to Rouen; and this was followed a year later by one from Paris to Bordeaux and back, which was won by a car equipped with a 4-h.p. engine, and is also memorable as marking the first adoption of pneumatic tyres for motor-cars. Then followed in annual sequence races from Paris to Dieppe, Amsterdam, and Berlin. At this point Mr James Gordon Bennett of New York presented a trophy for a regularised international contest to evidence the advance of the nations in motor-car construction. The first race for this was held from Paris to Lyons, and was won by France. This phase of racing competition died out because it became unreal, and produced cars unsuitable for ordinary purposes. In England it was supplanted in 1905 by the Tourist Trophy Race promoted in the Isle of Man by the Royal Automobile Club. This contest was soon abandoned because its object had been attained—the development of a car of moderate horse-power capable of considerable speed on a low-fuel consumption. The foundation of Brooklands track, a huge cement-surfaced course over two miles in circuit constructed by private enterprise at Weybridge, Surrey, helped to suppress road-racing in the United Kingdom. For many years the Royal Automobile and other clubs had conducted reliability trials which enabled designers to improve their cars, and the motoring public to distinguish between the types offered them. These also in time outlived their usefulness, and were abandoned in 1910. The Great War of 1914–18, fought upon motor transport, tested every type of engine, and improved the general design. The tax of £1 per horse-power has had a curious effect on the course of design in Britain. For this purpose the horse-power is not the actual horse-power, but is calculated according to a formula which takes into account the bore of the cylinder but not the stroke. Manufacturers have therefore striven to produce cheap light cars with a small rated horse-power. In America the cheapness of petrol and lowness of tax have not brought about the same type of high-compression, high-efficiency, small-capacity engine.

Concurrently with the rise of motoring, organisations to promote, conserve, and protect motoring interests grew up in every country. The Automobile Club of Great Britain and Ireland was founded in 1897, and obtained the prefix Royal in 1907. The Motor Union, founded by the Automobile Club in 1902, broke away from it in 1907, and became fused with the Automobile Association (founded in 1905) in 1910.

Motril, a town of Spain, 31 miles S. by E. of Granada, with factories and lead-mines. The port is at Calahonda, $6\frac{1}{2}$ miles SE. Pop. 17,000.

Motto, in Heraldry, a word or short sentence which forms an accompaniment to a coat-of-arms, crest, or household badge; it was called in Scotland the 'ditton.' In France and Scotland it was frequently placed above the crest, in England almost invariably below the escutcheon.

Mouflon (*Ovis Musimon*), the wild sheep of Corsica, Sardinia, central Asia, &c. See ARGALI, and SHEEP.

Moukden. See MUKDEN.

Mould, the common name of many minute fungi which make their appearance, often in crowded multitudes, on decaying or diseased plants and animals and vegetable substances. To the naked eye they often seem like patches of fine cobweb, which are shown by the microscope to consist of cellular threads. Their structure and history are described in the article FUNGI, from the

systematic part of which it will be seen that the popular name is applied to many very different forms—e.g. the common White Mould (*Mucor mucedo*), the Bread Mould (*Euotium Aspergillus-glaucus*), the mould of fruit and jam (*Penicillium glaucum*), &c. See also DRY ROT.

Mouldings, the curved and plane surfaces used as ornaments in cornices, panels, arches, &c., and in all enriched apertures in buildings. In classic architecture the mouldings are few in number, and definitely fixed in their forms. The illustration shows (1) the Echinus, (2) Cyma Recta, (3) Cyma Reversa, (4) Scotia, (5) Torus; another is the Fillet (q.v.); and each of these mouldings has its proper place assigned to it in each order (see COLUMN). In Gothic architecture, and all other styles, the mouldings are not reduced to a system as in the Greek and Roman styles, but may be used in every variety of form at the pleasure of the artist. Certain forms generally prevail at one period in any style. Thus, in Gothic architecture the date of a building may in many instances be determined by the form of the mouldings. The Norman mouldings were very simple in outline, and frequently enriched with the zigzag and billet ornaments. Fig. 6 is a common Norman form.

Classic Mouldings.

In the English style the mouldings are also simple in outline, and are usually arranged in rectangular divisions, as in fig. 7, and consist of alternate rounds and hollows. In

Various Mouldings.

late examples of this style the fillet was introduced (fig. 8) and led to the more elaborate form of mouldings during the Decorated period (fig. 9). The mouldings of the Perpendicular style are generally flatter and thinner than the preceding, and have large hollows separated by narrow fillets.

Moulins, the capital of the French department of Allier, on the right bank of the river Allier, here crossed by a handsome stone bridge of thirteen arches, lies 196 miles by rail SSE. of Paris and 124 NW. of Lyons. A clean, well-built town, with pretty promenades, it has a cathedral (1468–1871), the choir old; a square tower of the old castle of the dukes of Bourbon; a 15th-century belfry; and the chapel of a former convent. Marshals Villars and Berwick were natives, and Clarendon wrote here great part of his History. Nor must Sterne's Maria be forgotten. Pop. 23,000.

Moulmein. See MAULMAIN.

Moulton. See MULTAN.

Moulting, a general name for the process by which birds lose some of their feathers, or crustaceans cast their cuticular shells, or young insects get rid of their outer husk in metamorphosis. The shedding of the hair in mammals and the sloughing of snakes, &c. are also analogous. See BIRD, CRAB, CRUSTACEA, HAIR, INSECTS, SNAKE, &c.

Moulton, LOUISE CHANDLER (1835-1908) was born in Pomfret, Connecticut, married at the age of twenty W. U. Moulton, a Boston publisher, and published children's stories, novels, essays, and poems. Her stories are unaffected and well constructed, full of grace and tenderness; her verse reveals the rarer gift of lyrical music. Here may be named *Bedtime Stories* (1873; followed by a second series in 1875, and a third in 1880); *Some Women's Hearts* (1874); *Miss Eyre from Boston*, &c. (1889); and *In the Garden of Dreams* (1890), a volume of charmingly tender and pathetic verse.

Moultrie, FORT, a fortress on Sullivan's Island, at the mouth of Charleston Harbour, South Carolina, celebrated for the repulse of a British squadron commanded by Sir Peter Parker, 28th January 1776. The fort, which had 26 guns and 435 men, and was commanded by Colonel William Moultrie (1731-1805), had been hastily built of palmetto logs, in two rows 16 feet apart, with the space between filled with sand. The spongy wood of the palmetto (*Sabal Palmetto*; see PALMS) was found to resist the cannon balls perfectly.

Mound-birds (*Megapodiidae*), a peculiar family of shy Gallinaceous birds, many of which lay their eggs, sometimes socially, in mounds of soil and vegetable matter. Others lay in holes in sandy soil. In neither case is incubation necessary, for sufficient warmth is afforded by the decaying vegetation or by the sun. The young are remarkably precocious, sometimes flying almost immediately after they extricate themselves. The headquarters are in the Australian region, but the range includes Samoa, the Nicobars, and the Philippines. Among the members of the family may be mentioned *Megapodius* (about the size of a small fowl), *Lipoa* (the Mallee Hen or Native Pheasant of South and West Australia), the 'Brush Turkey' (*Catharturus lathami*) of East Australia, and *Talegallus* of New Guinea, one species of which makes a mound 11 feet high with an internal temperature of 93° F. See Wallace's *Malay Archipelago*, and Hickson's *Naturalist in North Celebes*; and the article TALEGALLA.

Mound Builders, the name given to a vanished race of North America, by whose labour the remarkable earth mounds found in the United States were raised. These mounds exist in extraordinary numbers over all the country between the Alleghany and Rocky Mountains, but chiefly in Ohio, Illinois, Indiana, and Missouri; they are abundant in all the Gulf States, and even farther south, and they extend at least as far north as the Great Lakes. Their usual height is from 6 to 30 feet, with a diameter of 40 to 100 feet. The majority are simply conical burial mounds, mostly rising from 15 to 25 feet, though one in West Virginia is 70 feet high and over 300 feet in diameter at the base. But very many others of these mounds are defensive, and others again have a religious origin. The fortifications, usually earthworks raised on heights near some water-course, embrace walls, trenches, watch-towers, and are too skilfully constructed to have been temporary defences: many archaeologists believe that there was a connected line of defensive works from New York to Ohio. In the Mississippi Valley, where the largest mounds are, these forts disappear; and it is supposed that the principal

enemies of the Mound Builders had their home in the east—perhaps in the Alleghanies. Some of the Ohio fortresses enclose over 100 acres, the walls of earth, winding in and out, in each case being several miles long. In the alluvial valleys other enclosures have been found, regular—circular, square, &c.—in shape; these have been called 'sacred enclosures,' but on very problematical grounds; and the same criticism applies to the identification of the smaller low mounds, from a few inches square to 50 by 15 feet, which have been called 'altars.' Of the 'temple' mounds, however, there are numerous examples, some very large: one in Illinois reaches a height of 90 feet, and measures 700 by 500 feet at the base; and another in Mississippi is 600 by 400 feet, and its topmost mound is 80 feet above the base. To these must be added the curious mounds constructed in the shape of animals, and sometimes extending to a length of 400 feet. They are most numerous in Wisconsin, but one of the most interesting is the serpent mound near Bush Creek, Ohio; Fort Ancient, the largest in the same state, is a mile long.

The general tendency is to connect the Mound Builders with the Natchez and kindred tribes whom the Spaniards found on the Mississippi, partly because their chief was both king and deity—he was regarded as the child of the sun—and so we find evidences of the religious feeling and the despotic power necessary to secure the accomplishment of such enormous works. All this favours the theory that the Mound Builders possessed a degraded form of the 'archaic civilisation' derived from Mexico and originally from Egypt. It is held by believers in the transmission of this culture that the mounds were built by seekers after gold, copper, and pearls—hence their distribution. The contents of the mounds support this view. It is evident that the Mound Builders, like the later Mexican tribes, were in the transition stage between the stone and metal age; copper they had obtained in the same primitive manner as it was obtained in Mexico, but the weapons and tools were stone implements, and knives of obsidian especially—the well-known sacrificial knives of the Aztecs—were common. Their art and manufactures were both of a low standard; but it is well known that the invaders of the Mexican tableland partly absorbed the civilisation they found there, partly degraded it. Finally, it may be mentioned that the sepulchral mounds yield many evidences of the cruel rites of their builders; and the pyramidal form of the 'temple' mounds is reproduced in the Teocalli (q.v.) of Mexico.

See W. K. Moorehead, *Primitive Man in Ohio* (1892); Thomas in Report of Washington Bureau of Ethnology (1894), and his *North American Archaeology* (1898); Perry, *Children of the Sun* (1923).

Mountain, the extreme party in the French Revolution led by Danton (q.v.) and Robespierre (q.v.), so called from their sitting in the highest part of the hall when the French Convention assembled. See MONTAGNARDS. For Mountain-leather, &c., AMPHIOLE; Mountain Meadow, DANITES; and for Mountaineering, ALPINE CLIMBING.

Mountain Ash, an urban district of Glamorganshire, 4 miles N.E. of Aberdare, included since 1918 in Merthyr-Tydfil parliamentary borough, has coal and iron mines; pop. 43,000. For the tree, see ROWAN.

Mountains, a name given somewhat vaguely to any region the surface of which rises with a more or less steep gradient to a height of 1000 feet or more. Mountains differ vastly in form—some assuming pyramidal or conical shapes, others

forming ridges, others occurring as irregular amorphous masses. Some again stand in more or less isolated positions, whilst in other cases very many crowd together, forming a billowy mass of elevated ground; and yet others, amongst which are the most prominent mountains of the globe, extend continuously in definite directions as long ranges and chains for hundreds or thousands of miles. Notwithstanding this diversity of form and of grouping, all mountains may be classified as—(a) Original or Tectonic, and (b) Subsequent or Relict Mountains. In the former class—original or tectonic mountains—are included all heights which owe their origin either (i.) to the piling or heaping of materials at the surface, or (ii.) to subterranean action which has resulted in the deformation of the earth's crust. Our subsequent or relict mountains have had quite a different origin. They have neither been built up by accumulation at the surface, nor are they due to crustal deformation. On the contrary, they are the remaining portions of former high land—relics or fragments of more or less lofty regions which have otherwise been gradually reduced and largely removed by the forces of decay.

(a) ORIGINAL or TECTONIC MOUNTAINS: (i.) *Accumulation Mountains*.—Volcanoes may be taken as the type of this class of mountains (fig. 1). These are of course formed by the accumulation of igneous materials around the focus or foci of

Fig. 1.—Volcano; Mountain of Accumulation.

eruption. Most volcanoes are more or less conical in shape; but in the case of those which have been long extinct the form has often been greatly modified by the denuding action of the subaerial agents. Some very ancient ones have been so demolished that frequently all that remains of them are mere stumps, formed of the hard crystalline rocks that plug up the pipes or flues through which the igneous materials found a passage to the surface.

(ii.) *Deformation Mountains*, so termed because they owe their origin to crustal deformation. Three types are recognised, namely, *folded mountains*, due essentially to flexuring and folding of the crust; *dislocation mountains*, due chiefly to fracturing and dislocation of the crust; and *laccolith mountains*, due to bulging of the crust over intrusive masses of formerly molten rock.

(1) *Folded Mountains* are much the most important type, constituting as they do the greatest chains and ranges of the world. The Alps, the Pyrenees, the Carpathians, the Himalayas are all folded mountains, and the same is the case with the Andes, the Rockies, and the corresponding chains and ranges of Eastern Asia and its archipelagoes. Mountains of this type indicate lines of weakness along which the rocks have yielded to excessive lateral compression by folding and doubling up during the sinking down of the cooled outer shell of the globe upon the cooling and contracting hot nucleus. The simplest structure presented by such mountains is shown in the Uinta Mountains of Wyoming and Utah. This is a flattened arch of strata, having a breadth of 50 miles and a length of 150 miles, which bulges up to a height of 5000 or 6000 feet above the plains on either side. It shows a broad plateau-like

surface which has been deeply eroded. Powell was of opinion that a thickness of $3\frac{1}{2}$ miles of strata had been denuded from its surface. In the Jura Mountains we have a series of parallel ridges, each ridge coinciding with a symmetrical anticlinal or saddle-backed arrangement of strata, while the intervening hollows occupy symmetrical

Fig. 2.—Symmetrical Flexures of Swiss Jura (Mountains of Elevation).

synclinal troughs (fig. 2). The tops of the anticlines are all more or less denuded. In the western part of the same range of mountains the flexures of the strata are mostly unsymmetrical

Fig. 3.—Unsymmetrical Flexures of Swiss Jura (Mountains of Elevation).

(fig. 3). In the Alps and many other great ranges the folding of the strata is still more pronounced, and the accompanying geological structures are often extremely complicated. Usually the folds are closely compressed, the crests of the anticlines tending to lean over in one general direction. To such an extent does this overfolding take place that strata becomes inverted or turned upside down, older beds being overturned upon younger beds. Frequently, indeed, so great has been the crustal compression that the folds have yielded, and the upper limbs have been driven forward over the lower, the dislocation being known as a 'thrust-plane.' Overthrusts of this kind vary in importance. In some cases the degree of displacement is inconsiderable, while now and again great mountain-masses have been pushed forward for 20 or 30 miles, or even greater distances. Very remarkable examples of such vast rock-translations have been noted in the Swiss Alps.

(2) *Dislocation Mountains*.—This is a type of deformation mountains which differs essentially from that described in the foregoing paragraph. In dislocation mountains rock-folding is either inconspicuous or absent. They owe their origin, therefore, rather to fracturing and displacement of the crust than to folding. Usually they occur at more or less isolated heights rising abruptly above adjacent lowlands, from which they are severed by vertical dislocations or 'faults.' Such mountains are termed 'Horste' by German geologists, who cite the Harz as a prominent example. Occasionally dislocation mountains occur as a series of parallel ranges or long rectangular blocks separated one from another by vertical faults. The ranges of the Great Basin, North America, are of this type, and of similar origin are the Vosges and the Black Forest of our own Continent.

(3) *Laccolith Mountains*.—This is the name given to a type of mountains which are well developed in Southern Utah and elsewhere in North America. A laccolith (stone cistern) is a mass of igneous rock of lenticular shape, connected with a subjacent pipe-like 'feeder.' The formerly molten rock has risen through this vertical pipe or fissure, but, being unable to burst across the superincumbent strata, it has been compelled to insinuate itself between the beds, and thus caused these to bulge upwards so as to produce a dome-like elevation at the surface. The typical laccoliths of North

America are of Late Tertiary age, and consequently are still in an excellent state of preservation.

(b) **SUBSEQUENT or RELICT MOUNTAINS.**—These have not been constructed or built as mountains, but are merely remnants or fragments of formerly more extensive elevated areas. They have been carved out of ancient tablelands or plateaus, and shaped into mountains by the gradual removal of masses by which they were at one time surrounded. Hence they are often termed 'mountains of circumsenuation.' Tablelands or plateaus are of various origin, but two well-marked types are recognised, distinguished from each other by their geological structure. In the one case a tableland consists of a great succession of approximately horizontal strata, so that its plain-like surface is an expression of this regular bedded arrangement. In the other case there is no such correspondence between surface configuration and internal structure. On the contrary, the rocks may show every possible variety of arrangement—not infrequently, indeed, the geological structure is quite as complicated as that of folded mountains. The two types may thus be distinguished as *plateaus of accumulation* (fig. 4) and *plateaus*

Fig. 4.—Plateau of Accumulation, A—B; showing Relict Mountains (m, m).

of erosion (fig. 5). The origin of the former is

Fig. 5.—Plateau of Erosion, A—B; showing Relict Mountains (m, m).

obvious—it is simply a more or less extensive area of strata which has been uplifted *en masse*, so that the horizontal arrangement of the beds has been left practically undisturbed. A plateau of erosion, on the other hand, represents an old land, often hilly or mountainous, which, after having been reduced by denudation to its base-level so as to form a plain, has been uplifted bodily.

All tablelands are in time more or less profoundly modified by erosion. Valleys are hollowed out by streams and rivers, and as its hydrographic system continues to develop, a plateau may eventually be so remodelled that its original configuration may be almost, or even entirely, obliterated. The primeval plain-like surface, in short, is replaced by regular or irregular ranges or groups of hills and mountains, all of which are necessarily 'relict mountains,' or 'mountains of circumsenuation' (figs. 4, 5).

In regions where the strata are not so highly inclined as in folded mountains, the part played by different kinds of rock and rock-arrangements in determining the characteristic features of the land is readily recognised. After prolonged denudation the less resistant rocks are usually found to occupy the lower grounds, while the harder or less readily reduced rocks form the heights. But geological structure is even a more important factor in determining the surface features worked out by erosion. In the annexed diagram (fig. 6), representing moderately inclined and undulating strata, three common types of hill are shown. The two beds *e, e* are beds of hard limestone intercalated in a series of less resistant strata. The

limestones being more durable than the beds above and below them have come to project so as to form *escarpments*, while the synclinal arrange-

Fig. 6.—Escarpments (*e, e*) and Hills of Circumsenuation (*h, h*).

ment of the strata—which is a relatively strong structure—has determined the position of the hills *h, h*. The isolated hill *d*, on the other hand, is due to the intrusion among the strata of a much harder igneous rock.

See the larger textbooks of Geology and Physical Geography; also J. Geikie's *Mountains: their Origin, Growth, and Decay*.

Mountmellick, a town in Queen's County, Ireland, on the Grand Canal, 7 miles N. of Maryborough by rail. It has a brewery, a tannery, and manufactures woollens and tobacco. Pop. 2300.

Mount Vernon, memorable as the residence and the burial-place of General Washington, is on the right bank of the Potomac, in Virginia, 15 miles below Washington. In 1856 the mansion and surrounding property were saved from the auctioneer's hammer and secured as a national possession by the Ladies' Mount Vernon Association, assisted principally by Edward Everett.—Mount Vernon has given its name to a number of places in the United States, the most important of which is a residential city of Westchester county, New York, a few miles above New York City; pop. 43,000.—Another is a city, the capital of Knox county, Ohio, on the Vernon River, 44 miles by rail NNE. of Columbus, with many handsome residences, and ample water-power; pop. 9000.

Mourning. See FUNERAL RITES.

Mousa. See BROCH.

Mouse (*Mus musculus*), a familiar rodent, representative of a large genus to which rats also belong. It is not necessary to describe the soft 'mouse-coloured' fur occasionally varying to white; the scaly tail so useful in climbing; the bright, conspicuous eyes, and the well-hidden cosy nest. Not less familiar is the way in which this tiny mammal has followed man everywhere over the earth; breeding all the year round, and bringing forth four or five young at a birth, its extraordinary fecundity sometimes causes a plague in a district (as in the wheat-fields of South Australia in 1890). It may be well, however, in the face of continually recurrent discussion, to note the power that at least some of the common mice have of making musical sounds, 'not squeaking,

1, Harvest-mouse (*Mus minutus*);
2, Long-tailed Field-mouse (*Mus sylvaticus*).

have of making musical sounds, 'not squeaking,

but singing, musically and rhythmically, in a high key, with a thin and wiry, but not displeasing quality—something like a weak-voiced canary bird. Mice are occasionally cannibals, and have been known to eat painters' putty with red lead in it. Larger than the above is the beautiful Wood-mouse (*M. sylvaticus*), an abundant pest in the fields and gardens of Europe, notable for the stores of grain and other food which it accumulates among the grass or just under the surface of the ground. Smaller than either, and smallest of British mammals, is the Harvest-mouse (*M. minutus*), which makes a neat globular nest of woven leaves among the grasses and reeds. The white-footed mouse (*Hesperomys leucopus*), which is exceedingly common in North America, has small cheek-pouches, structures best developed in the related family of Cricetinae or hamsters. Corresponding to the European harvest-mice are the American species of Ochetodon, of which *O. humilis* measures only about 2 inches in length, not including the tail. Finally, the Water-mice (*Hydromys*) of Australia may be noted as remarkably divergent. The name is sometimes extended, as we have seen, to include the smaller species of other genera than *Mus*, rat being an equally wide title for the larger forms. But, while the wide application of the name is naturally justified, care must be taken to keep the shrews (*Sorex*) in their entirely distinct, though somewhat analogous, position among Insectivora. See RAT, SHREW, VOLE.

Mousquetaires, the mounted body-guard of the kings of France, all of noble birth, were organised by Louis XIII. and disbanded in 1815.

Moussorgsky. See MUSSORGSKI

Mousterian, Le Moustier. See ANTHROPOLOGY.

Mouth. See the articles dealing with Palate, Digestion, Teeth, Tongue, Cancrum Oris, Salivation, Scurvy, &c.

Moveables. See HERITABLE AND MOVEABLE.

Moville, a seaside resort in County Donegal, on Lough Foyle, 19 miles NNE. of Londonderry. It is a calling-station of Transatlantic steam-packets; pop. 1000.

Moving Plant (*Desmodium gyrans*), a papilionaceous plant of India, remarkable, as are also some other species of the same genus, for the spontaneous movement of the leaves. See PLANTS (MOVEMENT OF).

Mowing-machine, a machine for mowing lawns and bowling-greens, differs from the reaping-machine in principle, chiefly in having revolving instead of horizontal cutters. The first successful mowing-machines in use in Britain were those invented by Shanks of Arbroath and by Green of Leeds about 1850. Improved forms of these are yet the best where the wear and tear are heavy. Some of their rivals, chiefly American, are preferable for lightness of draught, and consequently ease and speed of performance.

Mowra, MOWA, or MAHWA SEEDS, the oil-yielding seeds of *Bassia latifolia* and *B. longifolia*; also called Illipe or Illupi nuts. The solidified oil or 'butter' is used as a substitute for or adulterant of ghi, and is made into soap and candles. See BUTTER-TREE, SAPOTACEÆ.

Moxa is a peculiar form of counter-irritation which was early practised in the East, particularly by the Chinese and Japanese, from whom it was learned by the Portuguese. One or more small cones, formed of the downy covering of the leaves of *Artemisia Moxa* (as used by the Chinese), or of the pith of various plants (as of the common sunflower), or of linen steeped in nitre, are placed on the skin over the affected part, and the ends remote

from the skin are ignited. The combustion gradually proceeds through the cone and forms a superficial eschar on the skin. The surrounding parts must be protected by a pad of wet rag, with a hole in it for the moxa.

Mozambique, or MOÇAMBIQUE, or PORTUGUESE EAST AFRICA, extends from the Rovuma to beyond Delagoa Bay, a distance of 1300 miles. A tongue extends along the upper Zambezi between Nyasaland and Southern Rhodesia. Mozambique is divided into two by the Zambezi River, while other principal rivers are in the north the Lurio, and in the south the Pungwe and the Limpopo. The coast belt is low and swampy; but the interior rises into high grass-covered plateau, with here and there forests, the chief of which is the Amatonga, of valuable timber. The soil is naturally fertile, and yields in addition to sugar (which during the war years rose to a very important industry, the banks of the Zambezi being the site of many factories) maize, rice, manioc, and abundance of products such as sisal, cotton, tobacco, Mauritius hemp, coconut, medicinal plants. The exports are sugar, ivory, ground-nuts, wax copal, oil-seeds, and minerals. The northern portion of the country was the scene of the latter part of the German East Africa campaign, and the Kionga Triangle, at the mouth of the Rovuma, was thereafter handed over to Portugal. Mining is little prosecuted, although the country is rich in minerals, gold, silver, iron, and copper. The population is estimated at about 3,500,000. There are several railways, including lines from Delagoa Bay to the Transvaal and to Swaziland, Beira to Rhodesia, and from Beira to the Zambezi for Nyasaland. The chief towns are Lourenço Marques, Beira, Mozambique, Tete, Quilimane, and Port Amelia. Chinde, at the mouth of the Zambezi, was practically wiped out by a cyclone in 1922. The Mozambique territories are administered by a governor-general residing at Lourenço Marques, assisted by a partly-elected government council and a provincial council. Certain districts, such as Zambezia and Nyasa, are administered by companies. There is a native force officered by Portuguese, and service is compulsory.

Mozambique, the former capital of Portuguese East Africa, stands on a small island almost closing the entrance to a magnificent bay. It has a fine government house, cathedral, and many interesting old Portuguese colonial buildings. The town faces the bay, the sea front being covered by the fort (founded by Albuquerque in 1508, which stands at the north end of the island) and the blank walls of many go-downs. The city has been superseded as capital of the colony by Lourenço Marques. It was a great slave-trading post, but now does not equal Lourenço Marques and Beira in its trade. Population of the island about 5000, of whom 4000 are natives and 500 Europeans.

Mozambique Channel, between Madagascar and the east coast of Africa, is about 1000 miles in length and 400 in average breadth. At its northern extremity lie the Comoro Islands.

Mozárabes. See MORISCOS; and for Mozarabian Liturgy, see LITURGY.

Mozart, WOLFGANG AMADEUS CHRYSOSTOM, was the younger child of Leopold Mozart, Kapellmeister to the Archbishop of Salzburg, and was born in Salzburg on 27th January 1756. Numerous anecdotes are related of his childhood, illustrating an almost incredible precocity of genius, whose early promise, however, was amply fulfilled in his after-life. On his first professional tour through Europe, when he was six years old, he was accompanied by his sister Marianne, and under their father's care the children visited Vienna,

Paris, Belgium, and London. The greatest triumphs of Mozart were won in Bologna, then the musical centre of Italy. The Philharmonic Academy there suspended the rule by which no one under twenty was eligible for membership, in order to elect this young prodigy of barely fifteen. The wonderful power of his memory was illustrated by a famous feat performed in this Italian tour. The Easter music in the Sistine chapel was jealously kept from the eyes of outsiders, and no copy of it was permitted to be made. After one hearing, Mozart wrote from memory a full and minutely correct vocal score. During all the years of childhood and boyhood Mozart had been ever under the immediate care of his father, until his twenty-first year, when, stung by the indignities heaped upon him at the archiepiscopal court, he asked permission to leave it. In September 1777 he left Salzburg for Paris, with his mother as companion and adviser; and from this date began that struggle with the world in which he was to be so soon overthrown. In Mannheim, which he visited on the way, he made the acquaintance of a new instrument, the clarionette, which he was the first to incorporate in the modern orchestra, and fell in love with Aloysia Weber, the second daughter of a poor man with a considerable family. For many obvious reasons Leopold Mozart was greatly disturbed, and the correspondence between the anxious loving father and the disappointed but always dutiful son throws a flood of light on the relation, as beautiful as it is rare, in which they stood to each other.

In Paris mother and son had to practise the strictest economy, for the mature musician no longer commanded the limitless admiration and interest so readily accorded to the prodigy fifteen years before. In poor lodgings and amid depressing surroundings the mother's health gave way; she died in her son's arms; and Mozart returned to the paternal roof in Salzburg.

In 1781, having re-entered the service of the archbishop, he followed him with the rest of the prelate's household to Vienna. Although the archbishop was proud to have such a famous artist in his suite, he hated Mozart, and even the compliments so easily won on all hands by the young man were made so many occasions to wound his proud spirit. At last, stung by the studied and systematic insult to which he was subjected by his patron, Mozart retorted in language more caustic than prudent, which procured him an instant and ignominious dismissal.

Mozart took lodgings with his Mannheim friends, the Webers, who had now settled in Vienna. The father, his firm friend, was now dead, and Aloysia was married; but her place in Mozart's heart was taken by her younger sister Constance, a very gentle and attractive girl. Constance made a loving and devoted wife, but a wretched manager. She kept her husband up to his engagements, and amused him by her powers as a story-teller; but debts and difficulties increased. Just a month previous to his marriage he produced the charming little opera, *Die Entführung aus dem Serail*, which paved the way for the next, *The Marriage of Figaro*, the most delightful of lyric comedies. With his magic wand he touched the somewhat coarse or at least questionable elements in Beaumarchais' play, and these assumed an ideal form in a supernatural atmosphere of pretty piquancy where naughtiness is unknown. The opera was more than a success, it created a furore; yet jealousy and court intrigue prevented any reward, any acknowledgment that the greatest living musician was labouring and hungering in their midst. More generous appreciation was offered him in Prague, and, being commissioned to write an opera for the theatre there, he set

to work on *Don Giovanni*. The summer-house and the little stone table on which most of the charming music was written are still shown in the gardens, where, amid the noise of conversation and skittles, he worked apparently undisturbed. The extraordinary success of *Don Giovanni* made it impossible for the court still to overlook the composer, and he was appointed 'Kammer-Musicus' to Joseph II., his duties being to supply dance-music for the imperial balls at a salary of £80 a year.

Pecuniary embarrassments pressed heavily on his heart once so light, and he writes of gloomy thoughts, which he has to repress with all his might. He had great hopes that a journey to Berlin, *via* Dresden and Leipzig, in company with his friend and pupil, Prince Lichnowski, might give some chance of bettering his condition; and indeed Frederick-William II. of Prussia was so delighted with him that he offered him the post of Kapellmeister with about £450 a year. But a sentimental loyalty prevented him from accepting it. Ever-increasing difficulties induced him to inform the emperor of the king of Prussia's offer, and when Joseph seemed painfully surprised, Mozart, confirmed in an unreasoning affection for a monarch who did so little for him, exclaimed: 'I throw myself upon your kindness and remain.' Joseph II. ordered a new opera, *Così fan Tutte*, but owing to his death, and the indifference to art of his successor Leopold II., the composer reaped no pecuniary benefit. He made one more desperate application for a regular post, and was rewarded by being appointed assistant and successor (without pay for the present) to the Cathedral Kapellmeister, who outlived him many years. His carelessness and improvidence beset him with endless petty embarrassments, and Constance's frequent illnesses, which necessitated prolonged visits to health-resorts, were an additional and serious drain on the precarious income. He was hastened towards financial ruin too by his heedless and overpowering generosity, often casting his pearls before swine—'false friends,' his sister-in-law terms them, 'secret blood-suckers and worthless people, intercourse with whom ruined his reputation.' In 1791, Mozart's health even then breaking down, an adventurer, a brother freemason, applied to him for help. This was Schikaneder, a theatre manager, who found himself in difficulties, from which he said only a new opera by Mozart could save him. He suggested the subject himself, *The Magic Flute*, and, seeing Mozart's failing health and uncertain powers of work, he took care to keep him under his own eye, giving him working accommodation in his own house, and keeping him in good humour with copious supplies of wine and frequent invitations to dinner. For a short time Mozart, harassed and ailing, sought to forget himself in a continual fever of excitement, and the lapses of these few sad weeks, multiplied and magnified, gave rise to the judgments which upon those who so hastily condemn reflect double the dishonour they would impute. As the struggle with the world became more unequal, as the iron entered deeper into his soul, his vision became clearer to read the mystery of life. In six weeks he wrote his three greatest symphonies, in which first throbs that intense expression of passion and 'Weltschmerz' which was to raise Beethoven, his stronger successor, to the highest place of honour in Music's temple.

In March 1791 he began the *Magic Flute*, which was produced on the 30th September; and, though it was at first coldly received, it rapidly conquered public opinion, and in the end made the fortune of the lucky Schikaneder. While he was at work on the opera Mozart received the famous visit about which so much mystery has been made.

One night a stranger, now known to have been the steward of a nobleman, Count Walsegg, appeared and commissioned him to write a Requiem Mass to be finished in a month. He enjoined the strictest secrecy, and departed as mysteriously as he had come. The month passed, and Mozart was just stepping into the travelling-carriage which was to take him to Prague for the production of a new opera, when the stranger again appeared and reminded him of his promise. The incident made a deep impression on him; and the idea that it was a summons from the other world grew upon the fevered brain and broken heart of the composer. He was really dying, and, as he worked hard at the Requiem, he felt, as he said, that he was writing it for himself. On the 4th of December a few friends met in his room to rehearse the part of the work which was finished, but the dying composer was unequal to the effort. During the evening he seemed, even in unconsciousness, to be occupied with his work until an hour after midnight came the last summons.

He was buried in the common ground of St Mark's Churchyard, and no friendly eye saw his remains laid in their last resting-place. When the bereaved wife made inquiries a few days afterwards she found that the gravedigger had been changed, and her search for the grave proved fruitless; thus no one knows where Mozart was buried. It was many years after his death that Vienna awoke to sense of her shame and erected a beautiful monument to the memory of her adopted son.

Mozart wrote 624 compositions; he left no branch of the art unenriched by his genius; and he takes a high place in all. Indeed, in opera and symphony, in spite of the more advanced writings of Wagner and Beethoven, he may be said to be second to none. Gifted with an inexhaustible vein of the richest, purest melody, he is at once the glory and the reproach of the Italian school (see OPERA); for, while he surpasses all Italians on their own chosen ground, his strict training in the German school placed at his service those wonderful resources of harmony and instrumentation in which the south-erners have always been deficient. His most important operas are those already mentioned, *Don Giovanni*, *The Magic Flute*, and *Figaro*. The first stands upon a pinnacle of its own in the history of opera. It has no rival, and commands the unlimited admiration of every true musician; the great deficiencies of the libretto are forgotten in the charm of the music, in the masterly combinations of effect shown in the finales and concerted pieces, and in the triumph of sustained dramatic power in the last scene. The greatest compliment that could be paid the *Magic Flute* is that it still holds its place as a classic on the opera-stage, in spite of the most incoherent and incomprehensible plot. The importance of the orchestration gives the work a place only second to *Don Giovanni*, and it has been a favourite study with all great opera-composers. *Figaro* is perhaps the most perfect opera of the three, for in it the plot is slight, and the time required for its development very short.

Of forty-one symphonies there are three which will occupy an honoured place so long as music exists. These are the C major (called the 'Jupiter'), G minor, and E♭. The first deserves its name from the proud and noble rhythm of the first part, and the absolute ease with which the last movement sets forth a triumph of the most complicated counterpoint. In the G minor beat the first distinct pulses of that great wave of romanticism and passion which was to flood with its influence all future musical development.

The E♭ is very lively and good-humoured and tender withal. It might almost be called a 'Carnaval,' written before Schumann had shown the

way to such titles. The quartets are very beautiful and exceedingly original; but they are not associated with Mozart's name as they are with that of Haydn, nor is the fame of the earlier creator overshadowed in this branch of the art as is the case in the realm of orchestral writing. His pianoforte sonatas, and those for the violin and piano, are of no great importance except in the development of musical form; but an exception must be made in the case of the *Fantasia in C minor*, which, like the G minor symphony, foreshadows much of the new school, and reaches even so far as the influence of Schubert. His Masses are all youthful works, with the faults of youth easily recognisable, and the marks of the haste with which they were supplied as occasion required. The *Ave Verum*, a late church composition, though simple, is very expressive and touching. The unfinished *Requiem* remains a noble monument of his genius.

The great authorities on Mozart's life are Otto Jahn (1856-59; 3d ed., rev. by Deiters, 1889; Eng. trans. by Townsend, 1882); and Wyzewa and Saint-Foix (1912); see also the Life by Nohl (Eng. trans. by Lady Wallace, 1877), that by Meinardus (1882), the English one by Holmes (1845; 2d ed. 1878); and Dent, *Mozart's Operas* (1913). Nohl edited the Correspondence (2d ed. 1877). See also the Life by Fischer (1888) of Mozart's second son, Wolfgang Amadeus (1791-1844), who wrote a few compositions of slight importance.

Mozdok, a town of Russian Caucasus, on the Terek, 58 miles N. of Vladikavkaz, with three large annual fairs for horses, sheep, cattle, &c. It grows excellent melons and wine. Pop. 15,000.

Mozly, JAMES BOWLING, an able theological writer and High Church divine, was born in Lincolnshire in 1813. Educated at Oriel College, Oxford, he became a fellow of Magdalen, vicar of Old Shoreham, canon of Worcester, and in 1871 regius professor of Divinity at Oxford. Mozley had great intellectual force, subtlety of analysis, and imaginative versatility, but he wrote without facility, and his style is not in keeping with his thought. He died 4th January 1878. See his *Letters* (1884).—His elder brother THOMAS (1806-93), rector of Plymtree, Devon, wrote *Times* leaders, and was the author of *Reminiscences chiefly of Oriel College and the Oxford Movement* (1882), and *Reminiscences, chiefly of Towns, Villages, and Schools* (1885).

Mozuffernugger. See MUZAFFARNAGAR.

Msket, or MTZKHET, a town of the Caucasus, at the confluence of the Aragwa and the Kura, 12 miles NNW. of Tiflis, claims to be the oldest continuously inhabited town in the world, and to have been founded by Mtzkhetos, fifth in descent from Noah. Down to the 5th century it was the capital of the Georgian kings. Now scarce more than a village, it is dominated by the cathedral, said to occupy the spot to which Christ's shroud was brought from Golgotha. It already existed in the 4th century, and the Georgian kings were crowned and buried in it. One of the best specimens of Georgian architecture is the walled nunnery of Samtavr, with two frescoed churches, a beautiful isolated belfry, and the cell of St Nino, who brought Christianity to Georgia. A fortified monastery overlooks the town. Numerous ruins of monasteries and churches, castles and palaces, are scattered along the banks of both rivers.

Mtzensk. See MZENSK.

Much Wenlock. See WENLOCK.

Mucilage is the term applied to the solution of a gum in water—thus, mucilage of acacia, mucilage of tragacanth. The term is also sometimes applied to the natural solution of gummy substances found in plants. See GUM.

Muckers, the popular name of a sect which sprung up at Königsberg in 1835. The movement

seems to have originated in the dualistic and theosophic views of John Henry Schönherr (1771–1826) concerning the origination of the universe by the combination of a spiritual and a sensual principle. The most notable of his followers were two clergymen, J. W. Ebel (1784–1861) and Diestel, both of whom were in 1839–42 degraded from their office. Hepworth Dixon (in his *Spiritual Wives*, 1868) pointed out the resemblance of the Mucker sect to the Agapemone (q.v.) and the Perfectionists (q.v.).

Mucor. See FUNGI.

Mucous Membrane. Under the term mucous system anatomists include the skin, mucous membranes, and true glands, all of which are continuous with one another, and are essentially composed of similar parts (see SKIN, GLANDS). The mucous membrane is divided into the alimentary mucous membrane (for which see DIGESTION), the respiratory (see NOSE, RESPIRATION), and the genito-urinary (see KIDNEYS, &c.).

Mucuna. See COWHAGE.

Mudania, a small town of Asia Minor, on the Sea of Marmora, 15 miles NW. of Brusa, of which it is the port.

Mudar (*Calotropis*), a genus of Asclepiadaceæ found in India, Persia, &c. The inspissated juice is used as a purgative and sudorific medicine. The bark yields a fibre, and the seed a floss resembling Kapok (q.v.).

Mudéjares. See MORISCOS.

Mud-fishes (*Dipnoi*), a small but interesting order, which in some respects link fishes to Amphibians. There are three extant genera, whose antique character is indicated by their wide geographical distribution—*Ceratodus* (or more strictly *Neoceratodus*) from Queensland, *Protopterus* from tropical Africa, and *Lepidosiren* from tropical South America. There are numerous extinct representatives, from Palæozoic, Triassic, and Jurassic formations. The term 'mud-fish' refers to the habit that *Protopterus* and *Lepidosiren* have of burrowing into the mud when the dry season sets in and remaining in a torpid state till the rains return. But *Ceratodus* never leaves the water. The term *Dipnoi* (double-breathers) refers to the fact that

Head of *Protopterus* (after Wiedersheim):
Showing fore-limb (a), entrance to gill-cavity (b), external gills (c).

while they have gills, the swim-bladder has become a lung, single in *Ceratodus*, double in the two others. Among other peculiarities may be noticed: the median segmented axis in the paired fins, the approximation to a three-chambered heart, the possession of a vein resembling the inferior vena cava of higher Vertebrates, the occurrence of multicellular glands in the skin, the external gills of the larvæ of *Lepidosiren* and *Protopterus* (and in some adults of the latter as well), the large eggs with total unequal segmentation as in Amphibians. All the three forms take both vegetable and animal food. The flesh of all three is much esteemed. The development of *Lepidosiren* was elucidated by Graham Kerr's re-

searches in the Chaco country in 1896.—Another kind of 'mud-fish' is a Ganoid (*Amia calva*), not uncommon in some of the fresh waters of the United States, which attains a length of two feet, is carnivorous in diet, and gulps air at the surface of water, the air-bladder having truly pulmonary functions. But it is not a Dipnoan.

See CERATODUS, FISHES, LEPIDOSIREN; also Sedgwick, *Student's Textbook of Zoology*, vol. ii. (1905), and Bridge in the *Cambridge Natural History*, vol. vii. (1904).

Mudie, CHARLES EDWARD (1818–90), founder of the celebrated library which bears his name, was born at Chelsea. Having started as a bookseller, he established his library in 1842, which became a limited company in 1864. He published poetical *Stray Leaves* (1873).

Mudir (Arab. *mudîr*), the governor of a village or canton (in Turkey) or of a province (in Egypt).

Mudki, often spelt MOODKEE, a village of the Punjab, India, 26 miles S. of the Sutlej, and on the old road from Ferozpur to Karnal. Here the first battle in the Sikh war of 1845–46 was fought (18th December 1845), when the British under Sir Hugh Gough repulsed the Sikhs, and Sir Robert Henry Sale, 'Fighting Bob,' was killed.

Mud Volcanoes. See VOLCANOES.

Mudwort (*Limosella aquatica*), a small scrophulaceous plant, rare in Britain, growing on the margins of ponds. It has a tuft of narrow leaves, and small pale-coloured flowers, and spreads by runners.

Muehlenbeckia, an Australian and South American genus of Polygonaceæ. The leaves of *M. platyclados* drop off, and their functions are performed by the flattened green branches.

Muermo, a Chilean tree of the small South American and Australian genus *Eucryphia*, forming the order Eucryphiaceæ. It furnishes a hard and valuable wood.

Muezzin (Arab. *Mu-zin* or *Mu-azzin*; sometimes *Mueddin*), the official attached to a Mohammedan mosque who announces the different times of prayer.

Mufti. See ULEMA.

Muggletonians, a sect that arose in England about the year 1651, and of which the founders were John Reeve and Lodowick Muggleton (1609–98), obscure men, but who claimed to have the spirit of prophecy. Muggleton was a journeyman tailor. He professed to be the 'mouth' of Reeve, as Aaron was of Moses. They affirmed themselves to be the two witnesses of Rev. xi. They asserted a right to curse all who opposed them, and did not hesitate to declare eternal damnation against their adversaries. They favoured the world with a number of publications, one of which—particularly directed to the Parliament and Commonwealth of England, and to his Excellency the Lord General Cromwell—was entitled a *Remonstrance from the Eternal God*. The prophets were at that time imprisoned as nuisances in Old Bridewell. Another publication was a *General Epistle from the Holy Spirit* in 1756; Muggleton's writings were collected again in 1832. He had assailed the Quakers, and was answered effectively by Penn and George Fox. He denied the doctrine of the Trinity, held anthropomorphist opinions, with many strange doctrines over and above, as that the devil became incarnate in Eve, &c. A few Muggletonians lingered in England well into the 19th century. See Jessopp's *Coming of the Friars*, and other *Essays* (1888).

Mugwumps, a title conferred, during the United States presidential election of 1884 (New York *Sun*, June 15), on such Republicans as threw over the nominee of their party for Cleveland, the

Democratic candidate, in the interests of civil service reform. The title implied a belief that these Independents set themselves up as superior to their former associates.—The word means 'big chief' in the Algonquin Indian dialects, and John Eliot, who spelled it 'Mugquomp,' employed it to translate 'leader' and 'duke' (as in Gen. xxxvi. 15) in his Indian version of the Bible.

Muhammad. See MOHAMMED.

Mühlberg, a town of Prussian Saxony, on the Elbe, 36 miles SE. of Wittenberg, where, on 24th April 1547, the Emperor Charles V. defeated John Frederick the Magnanimous, Elector of Saxony. See SCHMALKALD.

Mühlhausen, a town of Prussian Saxony, on the Unstrut, 25 miles by rail NNW. of Gotha. An important imperial free city in the 13th century, it came to Prussia in 1802, to Westphalia in 1807, and again to Prussia in 1815; and it is still an active centre of commerce, with manufactures of woollen and cotton goods, hosiery, &c. Pop. 34,000.

Muir, JOHN, a distinguished Sanskrit scholar, was born in Glasgow in 1810, studied at the university there and at Haileybury, and at eighteen went out to Bengal to join the East India Company's Civil Service, in which he remained for twenty-five years. His last years were spent in Edinburgh, where he died, March 7, 1882. Muir was a munificent patron of learning, and himself a scholar of unusually wide intellectual and spiritual sympathies. He founded and endowed a chair of Sanskrit in Edinburgh, as well as prizes for high attainments in that language, and also provided the funds for a lectureship in comparative religion. His great work was his *Original Sanskrit Texts on the Origin and History of the People of India, their Religion and Institutions* (5 vols. 1858-70; 2d ed. 1868-73). Another book is *Metrical Translations from Sanskrit Writers* (1878).

SIR WILLIAM MUIR, his brother, was born in 1819, and at eighteen joined the Bengal Civil Service after having attended lectures at both the universities of Edinburgh and Glasgow. He rose rapidly in rank, was made K.C.S.I. in 1867, and was lieutenant-governor of the North-west Provinces, 1868-74, and Financial Minister to the government of India, 1874-76. After his return to England he sat on the Council of India in 1876-85, and from 1885 till 1903 he was Principal of the university of Edinburgh. He early became an eminent Arabic scholar, and his *Life of Mahomet* (4 vols. 1858-61; enlarged ed. 1912) and *Annals of the Early Caliphate* (1883) are works of solid and enduring value. Other books are *The Corân, its Composition and Teaching, and the Testimony it bears to the Holy Scriptures* (1878); *Extracts from the Corân* (1880); and *The Early Caliphate and Rise of Islam, the Rede Lectures for 1881*. He died 11th July 1905.

Muirkirk, a town of Ayrshire, 26 miles E. by N. of Ayr, bleakly situated, 720 feet above sea-level. It is the seat of great ironworks, dating from 1787, and chemical works. Pop. 3600.

Mukaddasi, an Arab geographer, born at Jerusalem, voyaged extensively for twenty years, and described Moslem lands in a work published in 985 A.D. It was edited by De Goeje in 1877; and the part relating to Syria and Palestine was translated from the Arabic for the Palestine Pilgrim's Text Society in 1837 by Guy Le Strange.

Mukden, or MOUKDEN, capital of Manchuria, is on a branch of the Liao, 425 miles NE. of Peking. Mukden is the Manchu name; the Chinese call it Shingking. Hence for five years the Russians controlled Manchuria, and soon after the fall of Port Arthur Mukden became the objective of three or more Japanese armies. The contest before Mukden

—one of the bloodiest in history—began in the end of February 1905, and ended with the rout of the Russians on the 12th March (see JAPAN). Previous to 1625 the town was called Shenyang; in that year Nurhachu, the founder of the late reigning family in China, made it his capital and called it Mukden. Numerous temples adorn the city. About four miles to the east is the tomb of Nurhachu. Mukden contains other imperial tombs of the same family. Good coal exists in the vicinity. Its port is Newchwang (q.v.); and it is an important point on the great railway system which connects the Siberian line with Port Arthur and the China Sea, and is rapidly transforming itself into a commercial and industrial centre.

Mulberry (*Morus*), a genus of trees of the natural order Moraceæ, natives of temperate and warm climates, with deciduous leaves, unisexual flowers in short, thick spikes, a 4-parted perianth, containing either four stamens or one pistil with two styles, the perianth of the female flowers becoming succulent and closing over the small pericarp, the whole spike coalescing into an aggregate fruit.—The Common Mulberry, or Black Mulberry (*M. nigra*) is a native of the middle parts of Asia, but was known to Theophrastus, and is now almost naturalised in the south of Europe. It is a low tree, much branched, with thick rough bark, and broad heart-shaped leaves, which are unequally serrated, and very rough. It is cultivated in the middle parts of Europe, and succeeds well in the south of

Common Mulberry (*Morus nigra*).

England, but in the northern parts of Britain it requires a wall. The perianth and stigmas are roughly ciliated, and the fruit is of a purplish-black colour, with dark red juice, fine aromatic flavour, and subacid sweet taste. The fruit is much esteemed for dessert; an excellent preserve and a pleasant light wine are made of it. The tree often produces its fruit in prodigious quantity. The wood is employed in cabinet-work, but is not of much value. The leaves are sometimes used for feeding silkworms. The Black Mulberry lives long; trees still existing in England are known to be more than 300 years old. It is propagated by seed, by suckers, by layers, or by cuttings. It succeeds best in a rich light soil.—The White Mulberry (*M. alba*) is a native of China, and has been there planted from time immemorial for the sake of its leaves, which are the best food for silkworms; on this account also it has been cultivated in the south of Europe since the 12th century. In North America it does not succeed farther north than 43° lat., being somewhat more impatient of

frost than the Black Mulberry. The perianth and stigmas are smooth; the fruit is almost white, and is much less palatable than that of the Black Mulberry, although in this respect there is great difference among the many varieties. A rob made of it is useful in sore throat. The best variety for feeding silkworms, on account of its rapid growth and abundant leaves, is that called the Philippine Mulberry. In India the White Mulberry is treated as a bush, and cut down twice a year; the shoots, stripped of their leaves, being thrown away, although the bark has long been used in China and Japan for making paper. It grows readily from cuttings. The root has a considerable reputation as a vermifuge.—The Red Mulberry (*M. rubra*), a native of North America, abounding particularly on the lower parts of the Missouri, endures severe frosts much better than either of the preceding, and is therefore preferred for cultivation in some parts of Europe. Its fruit is deep red, and almost as pleasant as the Black Mulberry. It forms a tree 60 to 70 feet high, with a circumference of about 6 feet; the wood is fine grained and strong.—The Indian Mulberry (*M. indica*) has black fruit of a delicate flavour, and the leaves are extensively used for feeding silkworms in China, Cochin-China, and Bengal.—*M. celtidifolia*, a Peruvian species, and *M. levigata*, the species most common in the north of India, produce pleasant fruit. There are numerous other species. The Mauritius Mulberry of Mauritius and Madagascar has been put in another genus, as *Ampalis madagascariensis*.

The Paper Mulberry (*Broussonetia papyrifera*) differs from the true mulberries in having the female flowers collected in a globular mass. The tree is of moderate size, or, in cultivation, a bush of 6 to 12 feet high, with leaves either simple or lobed, a native of India, Japan, and the islands of the Pacific Ocean, but now not uncommon in pleasure-grounds in Europe and North America. The islanders of the Pacific cultivate the Paper Mulberry with great care. They make a kind of clothing from the bark, using for this purpose the bark of small branches about an inch in diameter, which they macerate in water, and then, scraping off the epidermis, they press and beat the moist slips together. The paper also which is used in Japan and many parts of the East is in great part made from the bark of the young shoots of this plant, which for this purpose is boiled to a pulp, and treated somewhat in the same way as the pulp of rags in Europe. When the shoots are cut, new ones spring up very rapidly. Silkworms eat the leaves of the Paper Mulberry. The fruit is oblong, of a dark-scarlet colour, sweetish, but insipid. *B. papyrifera* also yields a fibre in Japan.

Mulcaster, RICHARD, philologist, (c.1530–1611), in 1548 became a scholar of King's College, Cambridge, but attracted no notice till 1555, when he removed to Oxford, and was chosen student of Christ Church, quickly becoming eminent for his knowledge of eastern literature. In 1561 he was appointed master of Merchant Taylors' School, and in 1596 master of St Paul's School. He enjoyed great reputation as a Greek and oriental scholar and successful schoolmaster. His English and Latin works were celebrated in their day, the principal being *Positions, &c. necessarie for the Training up of Children* (Lond. 1581) and *Elementarie on the Right Writing of our English Tung* (1582). He was early addicted to dramatic composition, and assisted in the performance of plays before Queen Elizabeth.

Mulder, GERARD JOHANNES (1802–80), was professor of Chemistry at Utrecht, best known from his investigations on protein and vegetable physiology.

Mule, the hybrid offspring of the male ass and the mare, much used and valued in many parts of the world as a beast of burden. The head, ears, croup, and tail show very distinctly the 'prepotency' of the ass; but in bulk and stature the mule is nearer the horse, and seems to excel both its parents in sagacity, muscular endurance, sure-footedness, and length of life. Though never much used in Britain, it has been common from ancient times in many parts of the East, and is a very important animal in most of the countries round the Mediterranean, and in the mountainous parts of South America. The best European breeds are found in France, Spain, and Italy; those of Kentucky, Missouri, Minnesota, and Mexico are also renowned. The carrier-mules of South America and elsewhere are driven in troops, each led by a bell-bearing old mare. Her they follow with such docility and affection that when the troops mingle in their halting-places they are readily separated by securing the leader. In ancient times mules were often reserved as the peculiar steeds of princes, and they are still used to draw the carriages of Italian cardinals and other ecclesiastical dignitaries. Mules are very surefooted, strong of limb and firm of hoof, clever at passing steep places and sharp turns, easy to please with food. They may be ridden, driven, or used for pack purposes. Their flesh is edible.

Mules are sterile when paired together, and there is no clear proof of what is often alleged, that a mule-mare may produce a foal to a horse or to an ass. Mule-mares have been known to adopt and suckle foals. The hinny or companion hybrid of the mule, the offspring of a female ass and a stallion, is not common, and is decidedly inferior in size, strength, and beauty. See ASS, HORSE, HYBRID, CANARY; and for the Spinning-mule, see SPINNING.

Mulgrave. See SHEFFIELD (JOHN).

Mulgrave Islands, a name given to some of the Marshall Islands (q.v.) from their discoverer, the navigator Lord Mulgrave (1744–92).

Mulhacén. See SIERRA NEVADA.

Mülhausen (Fr. *Mulhouse*), a town of Alsace-Lorraine, on the Ill and the Rhone and Rhine Canal, 68 miles by rail SSW. of Strasburg and 20 NW. of Basel. It consists of three parts, the old town, the new town, and the artisans' town, and is a place of first-rate industrial importance. The cotton manufacture employs many thousands of work-people in the town and adjacent villages. Besides this, it has printing and dye works for cotton, linen, calico, wool, and silk fabrics, chemical factories, iron and other metal works, and shops for making machinery, railway plant, &c. Pop. (1821) 13,027; (1861) 45,887; (1885) 69,759; (1910) 105,488; (1921) 98,393. Mülhausen, which existed as early as 717, was made a free imperial city by Rudolf of Hapsburg in 1273. By siding with some of the Swiss cantons in the 14th century it was enabled to maintain a certain degree of neutrality in the feuds between the empire and France. In 1515 it joined the Swiss Confederation, and in 1528 adopted the Reformed faith. But in 1798 it was incorporated with France, and began to come to the front as an industrial place after 1829. It is noted for the excellent arrangements made for the housing, &c., of the working-classes. It became a town of the German empire after the war of 1870–71. It was occupied by the French in August 1914, ceded to France with the rest of Alsace in 1919, and included in Haut Rhin.

Mülheim, (1) a manufacturing town of Rheinland, on the river Ruhr, 16 miles N. of Düsseldorf. It has great ironworks and an extensive trade in coal. Pop. (1875) 15,445; (1919) 128,205.—(2) MÜLHEIM-AM-RHEIN is now part of Cologne.

Mull, an Argyllshire island, the largest of the Hebrides after Lewis and Skye, is separated from the mainland by the Sound of Mull (19 miles long and $1\frac{1}{2}$ to $3\frac{1}{4}$ miles wide), and is engirt by a number of smaller islands—Gometra, Ulva, Staffa, Iona, &c. It is 347 sq. m. in area, and has a maximum length and breadth of 30 and 29 miles, but is so deeply indented, especially towards the Atlantic, by a dozen sea-lochs and bays—the chief, Loch-na-Keal and Loch Scridain—that the coast-line cannot be less than 300 miles. The rocks are chiefly volcanic, with fine red granite in the south-west; and the surface is mountainous. Benmore (3185 feet) is the loftiest summit, Bentalloch the most beautiful, where there is much that is beautiful—these misty heights, the stretching moors, the sea-cliffs at Carsaig, the terraced basaltic plateaus, the glens, streams, and lakes, and the patches of wood and green pasture. The climate is good for the Highlands, and the soil of fair fertility, but grazing answers much better than corn-crops. Tobermory (q.v.), in the north, is the only town. Aros and Duart Castles are interesting ruins; and Mackinnon's Cave was pronounced by Dr Johnson 'the greatest natural curiosity he had ever seen.' Pop. 3800, of whom the majority are Gaelic-speaking.

Mullein, the common English name of the genus *Verbascum*, belonging to the Scrophulariaceæ, and containing some two hundred species, of which six (Great Mullein, White, Dark, Moth, &c.) are natives of England, and have been naturalised in the United States. The leaves and stem (2 to 4 feet high), of the common and larger species, are covered with a dense, woolly growth; the flowers form a dense spike a foot long.

Müller, F. MAX-. See MAX-MÜLLER.

Müller, FRITZ (1821-97), naturalist, Darwin's 'prince of observers,' born near Erfurt, studied natural history and medicine at Berlin and Greifswald, and went in 1852 to Blumenau in Brazil. *Für Darwin* (1864) did much to advance Darwinism. He published also important observations on butterflies.

Müller, HERMANN (1829-83), brother of Fritz Müller (q.v.), was born at Mühlberg, studied at Halle and Berlin, and became a teacher at Lippstadt. He wrote on the local fauna and flora; but his renown rests on his *Befruchtung der Blumen durch Insekten* (1873) and other books on insect-pollination of flowers.

Müller, JOHANNES, one of the most eminent physiologists of the 19th century, was born at Coblenz on 14th July 1801, studied at Bonn and Berlin, chiefly anatomy and zoology, and in 1826 was appointed professor of Physiology and Anatomy at Bonn; in 1833 he succeeded Rudolphi as professor of Anatomy and Physiology at Berlin, and held that post until his death, 28th April 1858. He is regarded as the founder of modern physiology, on the ground that he summed up the work of his predecessors, instituted the methods of experimental and microscopic investigation of physiological properties, himself carried out and recorded most valuable observations in connection with the mechanism of sight, hearing, and voice, and the chemical and physical properties of chyle, lymph, and bile, and studied in an original and fruitful way the phenomena of reflex action and the glands. Moreover, his *Handbuch der Physiologie des Menschen* (2 vols. 1833-40) exercised a great influence. Müller was scarcely less eminent as a student of comparative anatomy; he observed rapidly and accurately, and possessed a remarkable insight into the interrelations of structural parts. In this department his most famous memoirs were those

on the Amphioxus, on fishes, the Echinoderms, and the Cæcilians.

Müller, JOHANNES VON, historian of Switzerland, was born 3d January 1752 at Schaffhausen, studied at Göttingen under Heyne, Schlözer, and others, and in 1772 was appointed professor of Greek at Schaffhausen. Already he had begun the investigation of Swiss chronicles and documents. From 1774 to 1780 he lived in Geneva, taught there, and wrote his *Allgemeine Geschichte* (3 vols. 1810), and published the first volume of his great work, *Geschichte der Schweizer*. Shortly afterwards he was given the professorship of History and a librarianship at Cassel, but resigned both posts in 1783. In 1786 he became librarian and councillor of state to the Elector of Mainz, and began the publication of his larger *Geschichte der schweizerischen Eidgenossenschaft* (5 vols. 1786-1808; improved ed. 1826). In support of the confederation of the German princes he wrote a *Darstellung des Fürstenbundes* (1787). In 1792, when Mainz was taken by the French, he went to Vienna, where the Emperor Leopold nominated him a member of the privy-council; but, a Protestant at a Roman Catholic court, he did not see much prospect of advancement, and in 1804 left Vienna for Berlin, where he was appointed historiographer of the Hohenzollern family, and wrote *Ueber die Geschichte Friedrich's I., Ueber den Untergang der Freiheit der alten Völker, and Versuch über die Zeitrechnungen der Vorwelt*. Introduced to Napoleon after the battle of Jena, he was appointed by him (1807) secretary of state in the new kingdom of Westphalia; but died at Cassel, 29th May 1809. His *Sämmtliche Werke* were published, 27 vols. Tübingen, 1800-19; new ed. 40 vols. Stuttgart, 1831-35. See Lives by Heeren (1820), Döring (1835), Monnard, in French (1839), and Thiersch (1881).

Müller, JULIUS (1801-78), a German theologian, was born at Brieg, brother of Karl Otfried Müller, the antiquary. He studied at Breslau and Göttingen, at first law, next theology, and after a severe mental struggle adopted opinions in religion opposed to those of the Rationalists. He was professor at Göttingen, Marburg, and Halle. His reputation chiefly rests upon *Die christliche Lehre von der Sünde* (Bresl. 1839; 6th ed. 1878).

Müller, KARL OTFRIED, classical archaeologist, was born 28th August 1797, at Brieg, in Silesia, studied at Breslau and Berlin, and in 1819 was appointed professor of Archaeology and director of the Philological Seminary at Göttingen. He died at Athens, 1st August 1840, whilst on a tour through Italy and Greece. His great design was to embrace the whole life of ancient Greece, its art, politics, industry, religion, in one warm and vivid conception—in a word, to cover the skeletons of antiquity with flesh, and to make the dry bones live. Thus his activity ranged over the whole field of Greek antiquity. We are indebted to him for many new and striking elucidations of the geography and topography, literature, grammar, mythology, manners and customs of the ancients. His work on the Dorians (*Die Dorier*; Eng. trans. 1839) forms the 2d vol. of his *Geschichte Hellenischer Stämme und Städte* (new and improved ed. 1844), his principal production; the first vol. deals with Orchomenos and the Minyans. The treatises on the ancient Macedonians (1825) and on the Etruscans (2 vols. 1828; new ed. 1877-78) continue the same line of investigations. Other valuable works from his pen are *Ancient Art* (1830; new ed. 1878; Eng. trans. 1847); *System of Mythology* (1825; Eng. trans. 1844); and *History of the Literature of Ancient Greece* (1846), undertaken at the request of the British 'Society for the Diffusion of Useful

Knowledge,' translated into English by Sir George Cornwall Lewis and Dr Donaldson, the latter of whom continued the work down to the taking of Constantinople. The German original was published by Müller's brother (2 vols. 1841; new ed. 1882-84). Müller issued useful critical editions of Varro, *De Lingua Latina* (1833); Festus, *De Significatione Verborum* (1839); and Æschylus, *Eumenides* (1833-35). See Memoirs by Lücke (1841) and F. Ranke (1870).

Mullet (*Mugil*), a genus of bony fishes, type of the family Mugilidæ. 'Gray mullets,' as they are called, are widely represented palatable fishes, chiefly found in coastal and brackish waters. Some tropical forms occur in fresh water. They feed on the small animals, confervoid algæ, and organic debris in the mud. In adaptation to this diet, there is an interesting filtering arrangement in the pharynx which keeps the gills from being

Common Gray Mullet (*Mugil capito*).

clogged. The useless stuff is in part rejected; in part passed down to the tough-walled, muscular, gizzard-like stomach, beyond which there is an exceedingly long intestine. The dentition is feeble. The colours are plain. Some attain to a weight of 10 or 12 pounds. Two British species are *M. chelo* and *M. capito*, the latter ranging from Scandinavia to the Cape of Good Hope. The Mediterranean gray mullet formed a favourite Roman dish, and the preserved roe is a special delicacy.

The so-called 'red mullets' (*Mullus*) are entirely different fishes in the family Mullidæ, nearly related to the sea-breams (*Pagrus*) and the American 'sheep's head' (*Diplodus*), one of the best salt-water fishes of the United States. From these and other Sparidæ the 'red mullets' differ in their very weak dentition, in the presence of two long erectile barbels, which, when at rest, lie hidden in two

Surmullet.

grooves behind the mouth. The body is slightly compressed, the scales are large and thin, the colours are brilliant. The food consists mainly of small crustaceans, worms, and the like, found in the mud. The Mullidæ are most abundantly represented in tropical and sub-tropical parts of the Indo-Pacific Ocean, but they are present in most warm seas, and extend to northern Europe. The surmullet (*M. surmuletus*) has three or four longitudinal yellow bands on a fine pink-red

ground colour, and was for a time erroneously regarded as the female form of *M. barbatus*, which is a distinct species or variety. It rarely exceeds two pounds in weight, and is much esteemed as a food-fish. The Romans used to bring surmullets alive into the banqueting-room, that the guests before eating the fishes might see the fine colours which they display as they die. There is a repulsive modern custom of securing (for market purposes) a relative permanence of the bright colour by scaling the fish before it is really dead.

Mullet. See HERALDRY.

Mullingar, the chief town of Westmeath, in Ireland, 50 miles WNW. of Dublin by rail, on the Royal Canal and the river Brosna. It is an important trading town, and a centre for anglers visiting the Westmeath lakes. Pop. 5500.

Mullinger, JAMES BASS (1834-1917), born at Bishop's Stortford, had a distinguished career at Cambridge, where in 1890 he became a lecturer on history. He wrote a history of his university (vols. i.-iii. 1873-1911), *The Schools of Charles the Great*, and other works.

Mullion, the upright division between the lights of windows, screens, &c., in Gothic architecture. Mullions are rarely met with in Norman architecture, but they become more frequent in the Early English style, and in the Decorated and Perpendicular are very common. They have sometimes small shafts attached to them, which carry the tracery of the upper part of the windows. In late domestic architecture they are usually plain. See WINDOW.

Mulock, MISS. See CRAIK.

Mulready, WILLIAM, genre-painter, was born at Ennis, in Ireland, 1st April 1786. When a boy he went to London with his parents, and at the age of fifteen entered as a student in the Royal Academy. Having tried classical subjects and landscape, he soon found his true sphere in genre-painting—painting subjects such as 'A Road-side Inn,' 'Horses Baiting,' the 'Barber's Shop,' and 'Punch' (1812), 'Boys Fishing' (1813), 'Idle Boys' (1815). He was elected an Associate of the Royal Academy in November 1815, and an Academician in February 1816. He also worked indefatigably at portrait-painting and the illustration of children's books; designed the famous 'Mulready envelope' for Sir Rowland Hill; and was throughout conscientious, careful in drawing, and rich in colouring. 'The Truant' (1835), 'The Seven Ages' (1838), 'The Sonnet' (1839), 'First Love' (1840) are famous works of his middle period; and his illustrations to the *Vicar of Wakefield* are well known. His later works, 'Women Bathing' (1849), 'Blackheath Park' (1849), 'The Toy Seller' (1862), showed failing powers. He died in London, 7th July 1863. See Stephens, *Memorials of Mulready* ('Great Artists' series, 1890).

Multan, or MOOLTAN, an ancient city of India, in the Punjab, stands on a mound formed by the ruins of ancient cities that occupied the same site, 4 miles from the left bank of the Chenab, the inundations of which sometimes reach Multan. It is surrounded on all sides except the south by a wall 10 to 20 feet high. The European quarter lies to the north and west of the city, whilst to the south is the citadel, which contains two Mohammedan shrines, the ruins of an ancient Hindu temple, and a massive obelisk (70 feet) to the memory of Vans Agnew and Anderson, murdered here in 1848. The vicinity abounds in mosques, tombs, shrines, &c. Manufactures of silks, cottons, and carpets are carried on; and the glazed pottery and enamel work enjoy a high reputation. Multan is an important centre of

trade in all the products of the Punjab. In 1849 Multan was taken by the British troops and annexed. Pop. (1868) 54,652; (1881) 68,674; (1891) 74,562; (1911) 99,243; (1921) 84,806.

Multiple-poining is a well-known form of legal process in Scotland, by which competing claims to one and the same fund are set at rest. A person who has funds in his possession, to which there are more claimants than one, is liable to be harassed by double distress; and hence he commences a suit called the action of multiple-poining, by which he alleges that he ought not to be made to pay the sum more than once; and as he does not know who is really entitled to payment, he cites all the parties claiming it, that they may fight out their claims among themselves. The corresponding process in England is Interpleader (q.v.).

Multiple Proportions. See CHEMISTRY.

Mummius. See CORINTH.

Mummy. See EMBALMING.

Mumps, a popular name of a specific inflammation of the salivary glands described technically as *Cynanche Parotidea*, or *Parotitis*. In Scotland it is frequently termed *The Branks*. The disorder usually begins with a feeling of stiffness about the jaws, which is followed by pains, heat, and swelling beneath the ear. The swelling begins in the parotid, but the other Salivary Glands (see SALIVA) usually soon become implicated, so that the swelling extends along the neck towards the chin, thus giving the patient a deformed and somewhat grotesque appearance. One or both sides may be affected, and in general the disease appears first on one side and then on the other. There is seldom much fever. The inflammation is usually at its highest point in three or four days, after which it begins to decline, suppuration of the glands scarcely ever occurring. In most cases no treatment further than to relieve fever, due attention to the bowels, and protection of the parts from cold, by the application of flannel or cotton-wool, is required, and the patient completely recovers in a week or a fortnight. The disease is infectious; and the infection probably remains for at least a fortnight after apparent recovery. Like most infectious diseases, it seldom affects the same person twice. It chiefly attacks children and young persons. A singular circumstance connected with the disease is that in many cases the subsidence of the swelling is immediately followed by swelling and pain in the *testes* in the male sex, and in the *mammae* in the female. The inflammation in these glands is seldom very painful or long continued, but is apt in the male to lead to permanent atrophy of the organs.

München. See MUNICH; also GLADBACH.

Münchhausen, KARL FRIEDRICH HIERONYMUS, BARON VON, a member of an ancient, noble family of Hanover, whose name has become proverbial as the narrator of false and ridiculously exaggerated exploits and adventures, was born 11th May 1720, at Bodenwerder, in Hanover, served as a cavalry officer in Russian campaigns against the Turks, and died at his birthplace, 22d February 1797. A collection of his marvellous stories, or stories attributed to him, was first published in English under the title of *Baron Münchhausen's Narrative of his Marvellous Travels and Campaigns in Russia* (Lond. 1785). They were compiled by Rudolf Erich Raspe, an expatriated German (whose financial enterprises were not creditable to him), and by other hack writers. The book went rapidly through several editions; and in 1786 appeared the first German version edited by the poet Bürger. Ellisen's edition (reprinted in 1890) is enriched by an admirable introduction. So is Secombe's English edition (1894), which points out many hits at Bruce, Montgolfier, &c. Several of the adven-

tures ascribed to the baron occur in Bebel's *Facetiae* (1508); others in Lange's *Deliciae Academicæ* (1765). See T. Secombe's Introduction to his edition (1894).—A Freiherr von Münchhausen (1813-86) became in 1850 head of the government of Hanover; and after the annexation of Hanover by Prussia (1866) he made himself a champion of the national party.

Muncie, capital of Delaware county, Indiana, 54 miles by rail ENE. of Indianapolis, is an important railway junction, and has manufactories of machinery, iron and steel, &c. Pop. 36,500.

Munday, ANTHONY (1553-1633), translator of chivalry romances and maker of ballads, plays, pageants, &c., was born and died in London, and was also an actor, a stationer, and a spy on the English Catholics at Rome.

Münden, a town of Hanover, at the influx of the Werra and Fulda to the Weser, 15 miles NE. of Cassel. Engirt by wooded hills, it has a school of forestry (1868), an old castle (with museum), various small manufactures, and a trade in timber. Pop. 12,000. See also MINDEN.

Mungo, St. See KENTIGERN.

Mongoose. See ICHNEUMON.

Munich (Ger. *München*), the capital of Bavaria, is situated in a flat, barren plain, 1700 feet above the sea-level, chiefly on the left or west bank of the impetuous Isar, a tributary of the Danube. By rail it is 440 miles SSW. of Berlin, 272 W. of Vienna, and 867 SE. of London. Several bridges, including a railway bridge, span the river to the suburbs on the right bank. The elevated site of the city and the neighbourhood of the Alps render it liable to sudden changes of temperature, sometimes ranging over 20° in twenty-four hours. The population, in 1801 only 48,885, was in 1880 230,023; by 1900 it had increased to 499,959; by 1919 to 630,711. The inhabitants are predominantly Roman Catholic. Munich is one of the handsomest cities in Germany, and perhaps the richest in treasures of art, while itself famous for its school of painting. Especially under King Ludwig I. (1825-48), who spent nearly 7,000,000 thalers in beautifying the city, it has been decorated with buildings of almost every style of architecture, many of them ornamented with frescoes and sculpture; wide and handsome streets have been constructed; and the squares and gardens adorned with statues and other monuments. Among the imposing buildings erected to house the public collections are the Glyptothek (1816-30), with its magnificent collection of ancient and modern sculpture, including the famous *Äginetan* marbles, discovered in 1811; the Old Pinakothek (1826-36), containing a large valuable collection of paintings by the old masters, besides engravings and many drawings, and a priceless collection of antique vases; the New Pinakothek (1846-53), devoted to the works of modern painters; the National Library, rich both in printed works and in MSS.; and the Bavarian National Museum, illustrating the history of civilisation and art. The New Palace includes an older palace and chapel, the Königsbau (1826-35), in the style of the Pitti Palace at Florence, with Schnorr's frescoes of the Nibelungenlied, and the sumptuously-adorned Banqueting Hall building. Other public structures are the Court Theatre, one of the largest in Germany, with room for 2600 spectators; the old and the new town-house; the Temple of Fame, a Doric colonnaded building containing busts of eighty illustrious Bavarians, in front of which rises the colossal statue of Bavaria, 65 feet high; the Generals' Portico (1844), a copy of the Loggia dei Lanzi at Florence; the conspicuous Maximilianeum, on its terrace on the right bank of the Isar, a college for civil servants, containing

a gallery of modern historical paintings; and various palaces and administrative buildings. Among the gates of Munich the most beautiful are the Gate of Victory, designed after Constantine's triumphal arch in the Forum; the old Isar gate, with its elaborate frescoes; and the Propylæa (1862), commemorating the Greek war of independence. The numerous churches are all, except two or three, Roman Catholic. The oldest is St Peter's (1294). The huge brick church of Our Lady (1468-88), the cathedral of the archbishopric of Munich-Freising, is remarkable for its two unfinished towers (325 feet), now capped with cupolas; in the interior is the elaborate tomb of the Emperor Louis the Bavarian. St Michael's, or the Jesuits' church (1583-91), contains a monument by Thorwaldsen to Eugène Beauharnais; the Theatine Church (1767) contains the royal burial-vault; the Louis Church (1830-44) is embellished with Cornelius's fresco of the 'Last Judgment'; the beautiful church of St Mariahilf (1831-39) is noted for its gorgeous painted glass and fine wood-carvings; and the basilica of St Boniface (1835-50) for its sixty-six monoliths of gray Tyrolean marble and resplendent interior decoration. The Court Chapel of All Saints is a perfect casket of art-treasures. Munich is admirably endowed with scholastic, literary, scientific, and benevolent institutions, including Royal Academies of Art and Science, a Polytechnic School, &c. The university, the second largest in Germany, was founded at Ingolstadt in 1472, was removed to Landshut in 1800, and transferred thence to Munich in 1826; its library is extensive; and its subsidiary institutions are numerous and well equipped. Adjoining the palace is the Court Garden, bounded on two sides by arcades adorned with frescoes; farther north is the English Garden, a park 600 acres in area; and on the right bank of the Isar are the attractive Gasteig promenades. The industrial development of Munich lags behind its æsthetic development. Its stained-glass works, iron, brass, and bell foundries, lithographing and engraving works, and manufactories of optical and mathematical instruments, and various artistic articles are, however, deservedly noted. Still more famous are the enormous breweries of Bavarian beer; of the annual production the greater part is consumed in the city itself, but much is also exported. Munich carries on a large trade in grain and in objects of art.

In 1158 Henry the Lion raised the *Villa Munichen* from its previous obscurity by establishing a mint and a salt-emporium within its precincts, the name (also appearing as *Forum ad Monachos*) being derived from the monks who owned the site. In the 13th century the dukes of the Wittelsbach dynasty selected Munich for their residence and fortified the town. In 1327 the old town was nearly destroyed by fire, and was rebuilt by the Emperor Ludwig the Bavarian very much on the plan which it still exhibits; but it was not until the fortifications were razed at the close of the 18th century that the limits of the town were enlarged to any extent. The true history of modern Munich is the account of its artistic development, with which the artists most closely identified are Klenze and Gärtner the architects, Schwanthaler the sculptor, and Cornelius and Kaulbach the painters. The modern Munich school of painting, once headed by K. von Piloty (1826-86) and W. Diez (1839-1907), is characterised by marked realism in colour and detail, in contrast to the romanticism of the older masters. The 1918 revolution was headed in Munich by Kurt Eisner, after whose assassination in February 1919 Munich experimented in 'council' government.

Municipal Architecture is shown in the buildings used for municipal purposes, such as town-halls, guildhalls, &c. These were first built

when the towns of the middle ages rose in importance and asserted their freedom. Those of North Italy and Belgium were the first to move, and consequently we find in these countries the earliest and most important specimens of municipal architecture during the middle ages. Municipal buildings always partake of the character of the architecture of the period when they were erected. In Italy, for instance, they are of the Italian-Gothic style in Vicenza, Venice, Florence, &c., during the 13th, 14th, and 15th centuries. In Belgium, during the same period, they are of the northern Gothic style, and are almost the only really fine specimens of the civil architecture of the middle ages now extant. The wrecked Cloth-hall at Ypres, and the town-halls of Brussels, Bruges (see BELFRY), Oudenarde, the Exchange at Antwerp, and many other markets, lodges, halls, &c., testify to the early importance of the municipal institutions in Belgium. We look for town-halls in vain in France or England till the development of industry and knowledge had made the citizens of the large towns so wealthy and important as to enable them to raise the municipal power into an institution. But from the 15th and 16th centuries there exist in Britain abundant instances of buildings erected for the use of the guilds and corporations and the municipal courts. See also GUILDHALL.

It is a curious fact that in France, where the towns became of considerable importance during the middle ages, so few municipal buildings remain. This arises from the circumstance that the resources of the early municipalities of France were devoted to aid the bishops in the erection of the great French cathedrals, and the townspeople used these cathedrals as their halls of assembly, and even for such purposes as masques and amusements.

Municipality (from Lat. *municipes*, from *munus* and *capio*, 'one who enjoys the rights of a free citizen'), a town or city possessed of certain privileges of local self-government, the governing body in such a town. Municipal institutions originated in the times of the Roman empire. The provincial towns of Italy, which were from the first Roman colonies, as also those which, after having an independent existence, became members of the Roman state, though subjected to the rule of an imperial governor, were allowed to enjoy a right of regulating their internal affairs. A class of the inhabitants called the *curia*, or *decuriones*, elected two officers, called *dumviri*, whose functions were supposed to be analogous to those of the consuls of the imperial city, and who exercised a limited jurisdiction, civil and criminal. There was an important functionary in every municipality called the *defensor civitatis*, or advocate for the city, the protector of the citizens against arbitrary acts on the part of the imperial governor. The municipal system declined with the decline of the empire, yet it retained vitality enough to be afterwards resuscitated in union with feudalism, and with the Saxon institutions of Britain. Some cities of Italy, France, and Germany have indeed derived their present magistracy by direct succession from imperial Rome. For British Municipalities, see BOROUGH, CITY. See also FREE IMPERIAL CITIES; and Dawson, *Municipal Life and Government in Germany* (1914).

Munjeet. See MADDER.

Munkacs, or MUKAČEVO, a market-town of the Ruthene territory of the Czechoslovak Republic, situated at the foot of the Carpathians, 101 miles by rail NE. of Debreczin, has mines of iron and rock-crystals. The citadel, built on an isolated height, resisted the imperial arms for three years (1685-88); and, having fallen in 1848 into the hands of the Hungarians, was captured by the Russians in the following year. Pop. 20,000.

Munkacsy, MICHAEL, painter, whose real surname was LIEB, was born at Munkacs, 10th October 1846. He went a turner's apprentice to Vienna, and studied painting there, at Munich, and at Düsseldorf, and in 1872 settled in Paris. Except a few portraits, his works are nearly all genre-pictures. Three classes may be distinguished—those depicting Hungarian life, mostly very dark in colouring; those illustrative of the social life of Paris, much lighter and brighter in tone; and historical pieces. Vigorous characterisation and pictorial breadth are conspicuous traits. Insane from 1897, he died 1st May 1900.

Munro, SIR HECTOR (1726–1805), of Novar, served in the Low Countries, embarked for India in 1760, won the great battle of Buxar in Bihar in 1764, and shared with Coote in the defeat of Hyder Ali. He returned to England in 1781, held military appointments at home, and spent his last years in improving his estate at Novar in Ross-shire.

Munro, HUGH ANDREW JOHNSTONE, Latin scholar, born at Elgin in 1819, was educated at Shrewsbury and Trinity College, Cambridge, elected fellow of his college in 1843, was professor of Latin in his university in 1869–72, and died at Rome, 30th March 1885. His greatest achievement was an edition of *Lucretius* (1864; 4th ed. 1885), text, translation, and notes, one of the finest and most brilliant works of British scholarship. His *Horace* appeared in 1869; his *Criticisms and Elucidations of Catullus* in 1878; and his translations into Latin and Greek verse were printed in 1884.

Munro, NEIL, born 3d June 1864 at Inveraray, became a journalist in Glasgow. *The Lost Pibroch* (1896) called attention to his insight into the Highland mind. Longer Highland romances and other tales followed—*John Splendid* (1898), *Gilian the Dreamer* (1899), *The Daft Days* (1907), &c.

Munro, SIR THOMAS (1761–1827), son of a Glasgow merchant, was educated at the Glasgow grammar-school and university, arrived as an officer in the H.E.I.C.S. at Madras in 1780 in time to serve in the operations against Hyder Ali in 1780–83, assisted in the reorganisation of Mysore, administered Kanara, and introduced the raiyatwari system of tenure, subsequently extended to most of Madras and Bombay. In 1807–15 he was in England, where he had great influence on Indian legislation. Having commanded in the second Mahratta war, he was in 1819 named governor of Madras. He died of cholera. See *Lives* by Gleig (1830), Arbuthnot (1889), and Bradshaw (1894).

Munster. See IRELAND.

Münster, capital of Westphalia, stands on a small stream, by rail 101 miles N. by E. of Cologne and 106 SSW. of Bremen. It retains numerous remains of mediæval architecture, including the mixed Romanesque and Gothic cathedral (12th to 14th century); Our Lady's Church, Gothic (1340); the Gothic church of St Lambert (14th century); the church of St Ludgerus, also Gothic, dating from 1330; the Gothic town-hall, in which, in 1648, the peace of Westphalia was signed (also signed simultaneously at Osnabrück, q.v.); the castle, built in 1767, and surrounded by fine pleasure-grounds, including botanical gardens; and the 16th-century town wine-cellar, in which are preserved some rare pictures of the Old German school. The old Catholic university of Münster was reduced in 1818 to an academy, which in 1902 regained the rank of university. Attached to it are a library, a natural history museum, and collections of art and antiquity. The industrial products of Münster include woollen, cotton, and silk fabrics, and paper, besides dyeing, printing, and enamelling. The trade is limited to linens, woollens, thread,

cattle, corn, &c. Pop. (1875) 35,705; (1885) 44,060; (1919) 100,452, mostly Catholics. Münster was known under the name of Mimigardevord in the time of Charlemagne, who in 791 made it the see of the new bishop of the Saxons, St Ludgerus. Towards the middle of the 11th century a monastery (whence Münster) was founded on the spot, and by 1186 it had grown into a town. In the 12th century the bishopric was elevated into a principality of the empire. In the 13th century the city became a member of the Hanseatic League; and in 1532 it declared its adhesion to the Reformed faith, notwithstanding the violent opposition of the chapter. During 1535 Münster was the scene of the violent politico-religious movement of the Anabaptists (q.v.). The bishop repossessed himself of the city, and in 1661 Bishop Bernhard built a strong citadel within the walls, and deprived the citizens of nearly all their liberties. In both the Thirty Years' War and the Seven Years' War Münster suffered severely. The bishopric, which since 1719 had been held by the Archbishop of Cologne, although it retained a special form of government, was secularised in 1803, and divided among various reigning houses. The Congress of Vienna gave the greater part of the principality to Prussia, a small portion being apportioned to Oldenburg, while Hanover acquired the territories of the mediatised Dukes of Aremberg. The bishopric was reconstituted in 1821.

Münster, SEBASTIAN, scholar, was born at Ingelheim in the Palatinate in 1489, studied at Heidelberg and Tübingen, and became a Franciscan monk, but at the Reformation he embraced the new doctrines (1529). He then taught Hebrew and theology at Heidelberg, and from 1536 mathematics at Basel, in which city he died on 23d May 1552. He brought out the first Hebrew Bible (1534–35) edited by a German; wrote *Cosmographia* (1544), a work on geography that kept its ground for more than a century; and published a Hebrew grammar, a Chaldaic grammar (1527), and lexicon (1527), and a Latin-Greek-Hebrew dictionary (1530).

Muntjak (*Cervulus muntjac*). These small deer, of which there are several species, appear to connect the true deer with the Chevrotains (q.v.); they inhabit the forest tracts of the oriental region—i.e. India, China, Java, Sumatra, Formosa, and the Philippines. The males have large canine teeth as in the Chevrotains; the horns are borne upon a long pedicel covered with hair, which seems to resemble the 'horn' of the giraffe.

Muntz's Metal. See BRASS.

Münzer, THOMAS, one of the leaders of the Anabaptists, (q.v.), was born at Stolberg, in the Harz, about 1489, studied theology, and in 1520 began to preach at Zwickau. His Christian socialism and his mystical doctrines soon brought him into collision with the Reformers and the town authorities. He thereupon made a preaching tour through Bohemia, Silesia, and Brandenburg, and settled in Thuringia (1523). Again deprived of his office, he visited Nuremberg, Basel, and other south German cities, and was finally in 1525 elected pastor of the Anabaptists of Mühlhausen, where he won the common people, notwithstanding Luther's denunciations of him, introduced his communistic ideas, and soon had the whole country in insurrection. But on 15th May 1525 he and his men were totally routed at Frankenhausen by Philip of Hesse. Münzer himself was captured in flight and executed on 30th May at Mühlhausen.

See *Lives* by Melancthon (1525), Strobel (1795), and Seidemann (1842); also Belfort Bax, *The Rise and Fall of the Anabaptists* (1903), and other works cited at ANABAPTISTS.

Muræna. See EEL.

Mural Circle, an astronomical instrument for

Mural Circle.

the observation of celestial bodies at their meridian passage. It consists of a large metal circle, turning on an axis the end of which projects from a solid stone pier or wall (whence the name), close to which the circle moves. The plane of the circle is set as nearly

as possible in the meridian. Fixed immovably to the circle is a telescope, which by turning the circle is made to point to the star to be observed, at the time of its meridian passage. The mural circle is now almost obsolete, modern improvements enabling all its work to be much better done by the transit circle.

Mural Crown. See CROWN.

Mural Decoration dates from very ancient times. The Egyptian and Etruscan monuments form an integral and important part of the history of Painting (q.v.), and have helped to mould the development of certain styles of art (see ARABESQUE). Incised work and reliefs have been largely employed. The Greeks tinted their temples and 'picked out' their sculptured friezes and pediments with colour; coloured bricks were used in Assyrian, and wall tiles (see POTTERY) in Moslem, architecture. Some of the Roman walls were built of tufa and red brick, coloured brick, terra-cotta, and variegated arrangements of marble were largely used in Italy. The plaster-work known as Sgraffito (q.v.) is especially adapted for this use. Many English churches of the mediæval period have been built of flint and stone, and much Tudor work of parti-coloured brick. Distemper and Fresco are described in separate articles; water glass is a silicate process of which there is an example in the Houses of Parliament. Mosaic-work is extensively used in floors and ceilings, but also occasionally employed in mural decoration. The dado of the Albert Memorial Chapel at Windsor is composed of slabs of inlaid marble hatched with coloured gold cement. See also TAPESTRY, WALL-PAPER.

Another system is that known as Encaustic Painting (Gr. *enkaustikē*, 'fixed by fire'), a manner of mural painting with a medium composed principally of wax, practised by the ancients. As the name implied that fire was used in the execution, some have been led to suppose that encaustic painting was the same as enamel painting; but notices by Pliny and other writers show clearly that it was a species of painting in which the chief ingredient used for uniting and fixing the colours was wax dissolved by heat. Various attempts have been made in modern times to revive it. About the middle of the 18th century Count Caylus and Bachelier, and in 1792 Mrs Hooker of Rottingdean, under the name of Emma Jane Greenland, made various successful experiments with this view. Encaustic painting was again taken up in Germany under the patronage of Louis I. of Bavaria, who commissioned Louis Schnorr to execute a series of historical subjects on the walls of the royal palace, Munich. For preparing her medium Mrs Hooker dissolved gum-arabic in water, afterwards adding gum-mastic, which was dissolved by stirring and boiling, and when the mixture had reached the boiling-point

she put in the wax. After painting the picture, she passed a thin coating of melted wax over it with a hard brush, and then drew over the surface an iron—for ironing linen—moderately heated. After the picture cooled it was rubbed with a fine linen cloth. The German method is somewhat similar, but some other ingredients are used; among these, potash with the wax; and, in place of an iron being passed over the surface, the wax is brought to the surface by a vessel containing fire being held at a little distance from the picture. It is also possible to employ a medium made of a mixture of turpentine and beeswax sufficiently plastic to be worked like oil. A modification of the system was also devised by Mr Gambier-Parry, and is known as Spirit Fresco. By his method the walls are coated with wax and gum compounded with spirit of lavender. The colours are ground with the same medium.

Murano, famous as the seat of the Venetian glass manufacture, is an island and town a little more than a mile north of Venice, with 6000 inhabitants. It possesses a fine 12th-century cathedral, and another church with some valuable pictures, including Paul Veronese's 'St Jerome in the Desert.' But the chief interest centres in the glass-factories—an industry established in the 13th century, and revived in 1860 by Antonio Salviati (1816-90).

Murasaki, a lady of the Japanese aristocracy, who, early in the 11th century, wrote a long novel *Genji Monogatari* and a diary. The former, translated by Mr Arthur Waley (*The Tale of Genji*, vol. i., 1925) was hailed by critics as one of the world's great novels, appealing especially to 20th century readers by its delicate sensitiveness.

Murat, JOACHIM, king of Naples, was the son of an innkeeper at La Bastide-Fortunière, near Cahors, in France, and was born 25th March 1767. He was at first intended for the priesthood, but the outbreak of the Revolution fired his enthusiasm; he entered the army, and soon rose to the rank of colonel. Attaching himself closely to Bonaparte, he served under him in Italy and in Egypt, distinguishing himself in many battles; rose to the rank of a general of division (1799); returned with Bonaparte to France, and rendered him most important assistance on the 18th Brumaire, by dispersing the Council of Five Hundred at St Cloud. Bonaparte now entrusted him with the command of the Consular Guard, and gave him his youngest sister, Caroline, in marriage. Murat held his usual post, the command of the cavalry, at Marengo, where he covered himself with glory, and in 1801 was nominated governor of the Cisalpine Republic. On the establishment of the French empire he was loaded with honours. He continued to command the cavalry in the armies led by the emperor, and contributed not a little to the victory at Austerlitz (1805), at Jena, at Eylau, and to many other victories. In 1806 the newly-erected grand-duchy of Berg (q.v.) was bestowed upon him, and on 1st August 1808 he was proclaimed king of the Two Sicilies by the style of Joachim I. Napoleon. He took possession of Naples, but the Bourbons, supported by the fleet of Britain, retained Sicily. By the moderation of his government he won the hearts of his subjects. In the expedition against Russia he commanded the cavalry, and indeed the army after Napoleon left it. After completing the rout at Dresden (1813), and helping to fight the disastrous battle of Leipzig, he concluded a treaty with Austria, and a truce with the British admiral, and promised the allies an auxiliary corps; but, as soon as he learned of Napoleon's escape from Elba and return to France, he commenced a hasty war against Austria. He was, however, defeated at Ferrara (12th April 1815), and again at Tolentino (2d May). With a few horsemen he fled

to Naples, where all was insurrection and commotion; thence he found his way to France. After Napoleon's final overthrow, he took refuge in Corsica, from which he proceeded with a few followers to the coast of Calabria, and proclaimed himself king and liberator, but, being presently taken prisoner, was tried by court-martial, and shot at Pizzo, on 13th October 1815. See biographical accounts by Gallois (Paris, 1828), Coletta (Paris, 1821), Helfert (Vienna, 1878), Weil (1910), and Hilliard-Atteridge (1911); and *Lettres et documents pour servir à l'histoire de Murat* (1907 et seq.).—His widow (1782–1839) assumed the title of Countess of Lipona, and resided in the neighbourhood of Trieste till her death. His two sons went to the United States, where the elder, NAPOLÉON ACHILLE (1801–47), settled in Florida, married a niece of Washington, and published *Exposition des Principes du Gouvernement Républicain en Amérique* (1833). The younger, NAPOLÉON LUCIEN CHARLES (1803–78), suffered reverses in fortune; but, returning to France after 1848, he attached himself to Louis Napoleon, who sent him as ambassador to Turin and made him a senator.

Muratori, LODOVICO ANTONIO, Italian antiquary and historian, was born at Vignola, in the duchy of Modena, 21st October 1672. In 1695 he was appointed a librarian of the Ambrosian Library at Milan. His first work was to issue collections of inedited Latin fragments, *Anecdota Latina*, followed later by *Anecdota Græca*. In 1700 he was recalled by the Duke of Modena to take charge of the D'Este Library and the ducal archives at Modena. In 1723 the first folio volume of his great collection, *Rerum Italicarum Scriptores*, was published, and between that date and 1751 twenty-eight more. This work contains all the chronicles of Italy from the 5th to the 16th century, illustrated with commentaries and critical notices. It was accompanied by a collection of dissertations illustrative of the religious, literary, social, political, military, and commercial relations of the several states of Italy during the same period, in 6 vols. folio, 1738–42, a work which, although far from being free from errors, is still regarded as a treasure-house of mediæval antiquities. Muratori likewise undertook a general history of Italy (*Annali d'Italia*, 12 vols. 4to, 1744–49); compiled in two vols. *Antichità Estensi* (1717); and published *Antiquitates Italicæ Mediæ Ævi* (6 vols. 1738–42), and a collection of Ancient Inscriptions (6 vols. 1739–42). In his later years he was attacked by the Jesuits on the ground of teaching heresies; but he found a protector in Pope Benedict XIV. He died at Modena, 23d January 1750. The *Antiquitates Italicæ* (vol. iii.) contains a catalogue or canon of the New Testament Scriptures, a fragment (the 'Muratorian Fragment'), apparently drawn up by a contemporary of Irenæus; see BIBLE. Lightfoot assigned it to Hippolytus; see his *Clement of Rome* (vol. ii. 1890). Muratori's *Collected Works* fill 36 volumes (Arezzo, 1767–80), and 48 volumes in another edition (Venice, 1790–1810). See the Life by his nephew (1756).

Murchison, SIR RODERICK IMPEY, geologist and geographer, was born at Tarradale, Ross-shire, 19th February 1792. He was educated at the grammar-school of Durham and the Military College, Great Marlow. He entered the army at an early age, served as an officer in Spain and Portugal, and was present at Vimeiro and the retreat to Coruña. Quitting the army in 1816, he devoted himself to science, especially geology, and travelled in various parts of the globe. He found the same sedimentary strata lying in the earth's crust beneath the Old Red Sandstone in the mountainous regions of Norway and Sweden, in the vast

and distant provinces of the Russian empire, and also in America. The result of his investigations was the discovery and establishment of the Silurian system, which won for him the Copley Medal of the Royal Society, and European reputation as a geologist. His subsequent exposition of the Devonian, Permian, and Laurentian systems increased and confirmed his reputation. He explored several parts of Germany, Poland, and the Carpathians; and in 1840–45, with De Verneuil and others, carried out a geological survey of the Russian empire. Struck with the resemblance in geological structure between the Ural Mountains and the Australian chain, Murchison in 1844 first predicted the discovery of gold in Australia. He was president of the British Association in 1846, and of the Royal Geographical Society in 1844–45, was re-elected in 1857, and continued to hold that post till 1870, when he was compelled to resign it by paralysis. Perhaps no contemporary did more to promote geographical science at home, and kindle the spirit of adventure among those engaged in Arctic exploration on the one hand and African discovery on the other. In 1855 he was made director-general of the Geological Survey and director of the Royal School of Mines. His investigations into the crystalline schists of the Highlands established a striking instance of regional metamorphism on a large scale. In 1870 he founded the chair of Geology of Edinburgh University. He died 22d October 1871. Most of his contributions to science appeared in the *Transactions* of the Geological and other Societies. His principal works were *The Silurian System* (1839); *The Geology of Russia in Europe and the Ural Mountains* (1845; 2d ed. 1853). See Life by Sir Archibald Geikie (1875).

Murcia, an ancient town of Spain, on the left bank of the Segura, by rail 46 miles SW. of Alicante and 50 N. by W. of Cartagena. It stands in the productive vale of Murcia, an old-fashioned Moorish town, embosomed in gardens of mulberry, orange, fig, palm, and other fruit trees. Almost the only notable buildings are the bishop's palace and the cathedral, this last begun in 1353, but reconstructed in 1521, and surmounted by a fine bell-tower. Silks, saltpetre, soda, gunpowder, musical instruments, and glass are manufactured; fruit-growing, the preparation of olive-oil, and the weaving of esparto also flourish. Pop. (1877) 91,805; (1921) 141,175. Alfonso X. of Castile took the city from the Moors in 1263; an earthquake almost destroyed it in 1829; and it was captured by the insurgents in 1843.—The province of Murcia has an area of 4453 sq. m. and pop. of 640,000. Along with the present province of Albacete it was an independent Arab kingdom for 27 years in the 13th century.

Murder is the unlawful and intentional killing of a human being by a human being. The most compendious statement of the distinctions drawn by the law of England between murder and manslaughter is given by Sir James Fitzjames Stephen in article 223 of his *Digest of the Criminal Law*. He says: 'Manslaughter is unlawful homicide without malice aforethought. Murder is unlawful homicide with malice aforethought. Malice aforethought means any one or more of the following states of mind preceding or co-existing with the act or omission by which death is caused, and it may exist when that act is unpremeditated: (a) an intention to cause the death of, or grievous bodily harm to, any person, whether such person is the person actually killed or not; (b) knowledge that the act which causes death will probably cause the death of, or grievous bodily harm to, some person, whether such person is the person actually killed or not, although such knowledge is accompanied by indifference whether death or grievous

bodily harm is caused or not, or by a wish that it may not be caused; (c) an intent to commit any felony whatever; or (d) an intent to oppose by force any officer of justice on his way to, in, or returning from the execution of the duty of arresting, keeping in custody, or imprisoning any person whom he is lawfully entitled to arrest, keep in custody or imprison, or the duty of keeping the peace, or dispersing an unlawful assembly, provided that the offender has notice that the person killed is such an officer so employed.' If the act of killing is done in the heat of passion caused by provocation, it is not murder, but manslaughter. The law presumes that every one who has killed another has murdered him, unless there are circumstances in the case to raise a contrary presumption. Murder is punished by death, manslaughter by penal servitude for life, or by a fine, according to the degree of culpability involved in the crime. The law of Scotland does not substantially differ from that laid down by Sir James Stephen, the chief distinction being that what in England is called manslaughter is in Scotland called culpable homicide. In the United States the only noteworthy distinction from the law of England is the recognition of different degrees of murder. An early act of the legislature of Pennsylvania distinguishes murder by poison or waylaying, or any other deliberate and premeditated killing, or murder committed in the furtherance of any arson, rape, robbery, or burglary, as murder of the first degree, and murder of all other kinds as murder of the second degree. The statute law of other states has similar provisions. In England and Wales during 1899-1923 the average annual number of murders committed and known to the police was 148. During that same period the average annual number of persons tried for murder was 64. The proportion of homicides of all kinds to population during this period was in England and Wales 1 to 200,000. From differences in legal classification and administration, it is notoriously difficult to compare the frequency of murder in different countries. But an estimate has been made that, whereas in England there are 7.1 murders per 10,000 deaths, in Germany the proportion is 6.4 murders to 10,000, in France 8, in Austria 8.8, in Switzerland 13.8, in Spain 23.8, in Italy as many as 29.4 per 10,000 deaths. The arguments for and against the abolition of Capital Punishment (q.v.) have been discussed in a separate article; see also EXECUTION, BIRTH (CONCEALMENT OF), SUICIDE.

Murdock, or **MURDOCH**, WILLIAM, inventor of gas for illuminating purposes, was born in August 1754, near Auchinleck, Ayrshire. His family traced their descent from some Flemish architects or engineers; and his father, a millwright and miller near Old Cumnock, designed the first iron-toothed gearing in Great Britain. Murdock worked under his father till he was twenty-three, then entered the employment of Boulton & Watt, Birmingham, and showed such marked ability that he was sent to Cornwall to superintend the erection of mining engines there. At Redruth he constructed in 1781 the model of a high-pressure engine to run on wheels. Watt showed some jealousy at these efforts; but Boulton offered him a reward for an engine capable of carrying two persons and the driver. His labours in Cornwall were arduous, though he had not more than £1 per week up till his forty-fourth year; and, a request for an increase of salary not being promptly acceded to, he made up his mind to change. The mining companies at last realising the value of his services, offered him £1000 a year as chief engineer at the mines. But he declined, returning to Boulton & Watt, who gave him a like salary as general manager of Soho Works. Mur-

dock's inventive brain was never idle; he introduced labour-saving machinery, a new method of wheel rotation, and an oscillating engine (1785). He also improved Watt's engine; introduced a method of casting steam cases for cylinders in one piece, instead of in segments; a rotatory and compressed-air engine; a steam gun; cast-iron cement; a method of heating by circulating water through pipes; a method of sending messages through an exhausted air tube; and many other inventions. His investigations in the distillation of coal-gas began at Redruth in 1792, when he lighted his offices and cottages by its agency. He publicly showed the results in 1797 and in 1798, the premises at Soho being lighted with gas. But he did not reap due profit from this useful invention. He died 15th November 1839. See a life of him by his kinsman Alexander Murdoch (1892).

Mure, **SIR WILLIAM**, of Rowallan, in Ayrshire, Scottish poet, was born in 1594, a kinsman of the author of *The Cherrie and the Slae*. He was wounded at Marston Moor, and died about the end of 1657. He translated into English sapphics Boyd of Trochrig's Latin poem, *Hecatombe Christiana*, but his principal work is his *True Crucifix for True Catholics* (Edin. 1629). His fine version of the Psalms dates from 1639. See the Scottish Text Society's edition of his poems (2 vols. 1898).

Mure, **WILLIAM**, was born at Caldwell in Ayrshire in 1799, educated at Westminster and the universities of Edinburgh and Bonn, represented Renfrewshire 1846-55, was Lord Rector of Glasgow University 1847-48, and died in London, 1st April 1860. Colonel Mure was for many years commandant of the Renfrewshire militia. He was the author of *A Critical Account of the Language and Literature of Ancient Greece* (5 vols. 1850-57), a work of sound scholarship and great learning; he maintains the unity of the Homeric poems. Mure also wrote *Journal of a Tour in Greece* (1842) and a couple of treatises on Egyptian chronology.

Muret (**MURETUS**), **MARC ANTOINE**, a celebrated humanist, was born at Muret, near Limoges, 12th April 1526. In early life in France he read lectures on civil law with great success, but subsequently in Italy he seems to have devoted himself entirely to literature till 1576, when he took orders. He afterwards resided in Rome till his death, 4th June 1585. His well-known *Orations*, though shallow, are remarkable examples of elocution in the style of Cicero. His poems, Latin and French, though graceful and fluent, are now considered worthless; but his learned criticisms and commentaries, *Variae Lectiones*, in 5 books, are held in great estimation. There are editions of his works by Ruhnken (1789) and Frotscher (1834-41), and 2 vols. of *Scripta Selecta* (1871-73) by Frey. See also the monograph by Dejob (Paris, 1881).

Murex, a genus of marine Gasteropods, nearly related to dog-whelks. The numerous species

Venus Comb (*Murex tenuispina*).

prey upon other molluscs, boring into them by means of the radula. The shells bear rows of

spines or rough fringes, very long in 'Venus Comb,' probably of protective value. Several species, e.g. *M. trunculus* and *M. brandaris*, used to be crushed to furnish the famous Tyrian purple (dibromindigo), which is a secretion of the mollusc. See DYING.

Murfreesborough, capital of Rutherford county, Tennessee, and from 1819 to 1826 capital of the state, is 33 miles by rail SE. of Nashville, and has several colleges. Close by was fought the bloody battle of Stone River, 31st December 1862 and 2d January 1863, between Generals Rosecrans and Bragg; the Confederate army was compelled to retreat, but the losses on both sides were nearly equal. Pop. 5000.

Murger, HENRI, novelist and poet, was born in Paris on 24th March 1822. He began life as a notary's clerk, and afterwards acted as secretary to Count Tolstoi, at a salary of about a pound a week. He gave himself to literature, and for several years led the life of privation and adventure which he has described in his *Scènes de la Vie de Bohème* (1845). At last his genius was recognised by Arsène Houssaye, the editor of the *Artiste*, and during his later years his popularity was secure. Every journal was open to him, but he wrote slowly and fitfully in the intervals of dissipation, and was never in easy circumstances. He died in hospital in Paris on 28th January 1861. His first and best novel, *Scènes de la Vie de Bohème*, is, says Mr Saintsbury, a work final and perfect, which deserves a place in the literature of humanity. A vivid transcript from the scenes, alternately sombre and jovial, of the writer's years of struggle, it is in parts infinitely pathetic, in parts irresistibly amusing. Murger had a rich gift of humour, but his predominant tone is one of poignant melancholy. *Le Manchon de Francine* is one of the saddest, as it is one of the most beautiful, short stories ever penned. He had uncommon literary skill, and could portray certain types of character admirably. But he had only one subject which he could handle successfully—the Bohemia of literary Paris. Next to the *Scènes de la Vie de Bohème*, his best prose works are *Scènes de la Vie de Jeunesse*, *Les Buteurs d'Eau*, and the short tales included in the volume entitled *Madame Olympe*. His poems, *Les Nuits d'Hiver*, are graceful, sincere, and often deeply pathetic, bearing strong traces of the influence of De Musset. One of them, *La Chanson de Musette*, is a lyric masterpiece—'a tear,' said Gautier, 'which has become a pearl of poetry.' Several of Murger's pieces were translated with rare felicity by Andrew Lang in his *Lays of Old France*. Murger was likewise the author of *Le Dernier Rendezvous*, *Scènes de Campagne*, *Le Pays Latin*, *Le Sabot Rouge*, *Les Vacances de Camille*, &c.

See the notices of Murger by Gautier, Houssaye, Janin, and Saint-Victor in *Les Nuits d'Hiver* (1862).

Murghab, a river that rises in the mountains north-east of Herat in Afghanistan, flows north-west, and loses itself in the desert of Turkestan beyond Merv.

Muriatic Acid. See HYDROCHLORIC ACID.

Muridae, a family of rodent quadrupeds, containing many genera and a very large number of species, distributed over all parts of the world, of which rats and mice may be regarded as typical examples. To this family belong also voles, lemmings, hamsters, gerbilles, &c.

Murillo, BARTOLOMÉ ESTEBAN, was born of humble parentage at Seville, and baptised 1st January 1618; and, after receiving some education, was placed with his relative, Juan del Castillo, to study painting. Having saved a little money, which he made by painting somewhat stiff and

rough religious pictures for the fairs of Seville and for exportation to South America, he went to Madrid in 1641, being then in his twenty-fourth year; was favourably noticed by his celebrated townsman, Velázquez; and through his influence was enabled to study the *chefs-d'œuvre* of Italian and Flemish art in the royal collections. In 1645 he determined to return to Seville, though advised to proceed to Rome by Velázquez, who offered him letters from the king. After settling in Seville, he painted eleven large and remarkable pictures for the convent of San Francisco. He at once became famous, and, receiving numerous important commissions, was soon acknowledged as the head of the school there. In 1648 Murillo married a lady of fortune; he now maintained a handsome establishment, and his house was the resort of people of taste and fashion. About this time he passed from his first or 'cold' style—dark with decided outlines—to his second or 'warm' style, in which the drawing is softer and the colour improved. Of the second style good examples are 'St Leander,' the 'Nativity of the Virgin,' and 'St Antony of Padua.' In 1656 he was engaged on four great semicircular pictures, which are the first examples of his third or 'vaporous' manner, the outlines vanishing in a misty blending of light and shade. The three styles, it should be said, are not strictly chronological, the warm style constantly reappearing. The Academy of Seville was founded by him in 1660, but he filled the office of president only during the first year. After this came Murillo's most brilliant period; eight of the eleven pictures painted in 1661–74 for the almshouse of St Jorge, including 'Moses striking the Rock,' 'Abraham and the Angels,' 'The Miracle of the Loaves and Fishes,' 'St Peter released from Prison,' and 'St Elizabeth,' are accounted his masterpieces. He executed some twenty pieces for the Capuchin Convent after 1675. He frequently chose the Immaculate Conception or Assumption of the Virgin as a subject, and treated them much alike; the famous 'Conception' now in the Louvre was sold in 1852 at the sale of Marshal Soult's pictures for £24,000. In 1681 he went to Cadiz, and while there fell from a scaffold when painting an altarpiece in the church of the Capuchins, returned to Seville, and soon after died from the injury he received, April 3, 1682. Murillo's pictures naturally fall into two great groups—scenes from low life, Gypsies and beggar children (mostly executed early in his life), and scripture and religious works. Of the former, by which he is largely known abroad, very few are to be seen in Spain. Though his best pictures show much technical skill, truth to nature, and sentiment of a kind, they seldom show ideal beauty or sublimity of feeling.

See Miss E. E. Minor, *Murillo* ('Great Artists' series, 1882), C. B. Curtis, *Velasquez and Murillo* (1883), the latter giving a list of 481 pictures; Calvert, *Murillo* (1908); and *Murillo: des Meisters Gemälde* (ed. Mayer, 1913).

Murman Coast is the north-east coast of the Kola Peninsula. The town of Murmansk, till 1917 Romanov (pop. 2000), on the Tuloma, north of Kola, is capital of the new government of Murmansk (pop. 20,000), a port open all the year.

Murphy, ARTHUR, dramatic and miscellaneous writer, was born in Roscommon in 1727. Intended by his father for business, he was placed in a London bank, but having, during his education at the college at St Omer, in France, reached extraordinary proficiency in Greek and Latin, he contracted literary and dramatic tastes. In 1752–74 he published the weekly *Gray's Inn Journal*, which obtained him the acquaintance of Dr Johnson. Disappointed of some expectations and already in debt, he went on the stage, and

made his first appearance as Othello. In one season he paid his debts, and left the stage with £400 in his pocket; and, determining to study law, he entered Lincoln's Inn in 1757. In 1758 he produced his first play, *The Upholsterer*, a successful farce; in 1762 he was called to the bar, but with so poor a result that in 1788 he retired. He continued to write comedies and other plays for the stage, and is said to have produced more stock pieces than any man of his time. His translation of Tacitus (1793) is excellent; but his *Essay on Johnson and Life of Garrick* did not add to his fame. His dramatic works fill 8 vols. Late in life he became a Commissioner of Bankrupts, and enjoyed a pension of £200 a year. He died in 1805. See his *Life* by Jesse Foot (1811).

Murrain is the generic term loosely used to designate a variety of diseases of domestic animals, but more generally restricted to the vesicular epizootic, popularly known as foot-and-mouth disease. It is a contagious, infectious eruptive fever, affecting cattle, sheep, and pigs; but is rarely communicable to birds, horses, or men. It is characterised by the appearance of little bladders or vesicles in the mouth, on the lips, gums, and tongue, on the coronets and interdental spaces of the feet, causing inability to eat, drivelling of saliva, sometimes heat and swelling of the udder, and lameness. The disorder runs a fixed and definite course usually in eight or ten days. Good nursing, comfortable lodgings, and a liberal supply of soft, easily digestible food, are the chief requisites for speedy recovery. A laxative may be given if needed. The mouth may be washed out twice daily with a mild astringent solution, which may be made with half an ounce of alum, oxide of zinc, or sugar of lead, to the quart of water. When the udder in milch cows, in which the complaint is usually most serious, is affected, it should be bathed with tepid water before and after milking, which must be attended to very regularly, the feet kept clean, loose horn removed, and washed occasionally with the lotion used for the mouth. Outbreaks of the disease have been met by isolation and by wholesale slaughter. In 1924 Frosch and Dahmen announced the discovery of the causal organism, a filter-passing bacillus which they claimed to have isolated, cultivated, and photographed (by ultra-violet light and the ultra-microscope). See also ANTHRAX, RINDERPEST, PLEURO-PNEUMONIA.

Murray, ALEXANDER, philologist, was born the son of a shepherd in the parish of Minnigaff, Kirkcudbright, 22d October 1775, and had hardly any education save what his father could impart, till 1788, when he was at school for a short time. Yet by diligent and omnivorous reading of all such books as fell in his way or could be borrowed, he, when engaged as a shepherd, acquired, besides a scholarly knowledge of English literature, a mastery of the classics, all the principal European tongues, and Hebrew. The fame of the learned shepherd led to an invitation to Edinburgh, where he obtained a bursary, gave private lessons, and continued his linguistic labours, which were extended to oriental tongues and ancient and modern Abyssinian. In 1806 he became minister of Urr, in 1812 professor of Oriental Languages in Edinburgh University; but he died 15th April 1813. His *History of the European Languages* was published in 1823.

Murray, DAVID CHRISTIE, novelist, was born 13th April 1847, at West Bromwich, in Staffordshire, and had served as reporter and then as war-correspondent (1877-78) for several newspapers, when in 1879 he published *A Life's Atonement* in 'Chambers's Journal.' In the same journal appeared *Val Strange* and *John Vale's Guardian*. Other

works are *By the Gate of the Sea*, *The Way of the World*, *Aunt Rachel*, *Old Blazer's Hero*, *The Weaker Vessel*, *Verona's Father*, *The Brangwyn Mystery* (1906). He died 1st August 1907.

Murray, EUSTACE CLARE GRENVILLE, the 'Roving Englishman,' was born 2d October 1819, the natural son of the second Duke of Buckingham. After studying at Oxford, he served till 1849 in the Austrian army; in 1851 joined the British embassy at Vienna as attaché; in 1853-54 went on a special mission to the islands in the Aegean Sea; in 1857 was attaché at Teheran; and in the next year consul-general at Odessa. For exposing in the public press in 1866 certain abuses connected with the foreign office he was dismissed the service. He spent the rest of his life in Paris, and died at Passy, on 20th December 1881. As a journalist he is best known for his brilliant papers in the *Daily News* and *Pall Mall Gazette*, and as an author by *The Roving Englishman* (1854-55), *Embassies and Foreign Courts* (1855), *History of the French Press* (1874), *Men of the Second Empire*, &c. (1872-74), and a few brilliant novels. Of the last, *The Member for Paris* (1871) is the cleverest, but *Young Brown* (1874), from the circumstances of its hero's birth, has the most interest.

Murray, SIR JAMES AUGUSTUS HENRY, was born at Denholm, Roxburghshire, in 1837, was educated at Minto school, removed to Hawick, and was appointed assistant-teacher in the parish school there, and afterwards master of a subscription academy. He next removed to London, filling the post of foreign correspondent in the *Oriental Bank* for some years. Later he became senior assistant-master at Mill Hill school. His work on the *Dialect of the Southern Counties of Scotland* (1873) established his reputation as a philologist. He was familiar with almost all European and a large number of oriental tongues. The great work of his life, the editorship of the *Philological Society's New English Dictionary*, issued by the Clarendon Press, was begun while he was at Mill Hill (1879), an iron building in his garden there being utilised for the assortment of the two tons of material to which he fell heir from his predecessors in the editorship, Herbert Coleridge and Dr Furnivall. This work has been continued at Oxford, where Sir James Murray, with a staff of assistants, devoted his whole attention to the task. He fought his way to the front rank as an authority in the history and derivation of words, and his great *English Dictionary* is the most thorough and important work of the kind ever undertaken. A civil list pension of £250 per annum was conferred upon him in 1884; and he was knighted in 1908. He died 26th July 1915, when the dictionary was all but complete to the end of T. Portions of the dictionary have been edited by Professor W. A. Craigie, Dr Henry Bradley, and Mr C. T. Onions. See memoir by Bradley (1919).

Murray, JOHN, the name of four generations of English publishers, will for ever remain associated with the palmiest days of English literature in the 18th and 19th centuries. The founder of the house, John M'Murray, was born in Edinburgh in 1745. He obtained a commission in the Royal Marines in 1762, and in 1768 was still second-lieutenant, when, disgusted with the slowness of promotion, he purchased the bookselling business of Paul Sandby, 32 Fleet Street, London, and dropping the Scottish prefix, became a bookseller and publisher. He brought out the *English Review*, and published the first two volumes of the elder Disraeli's *Curiosities of Literature*, &c. He died 16th November 1793, and was succeeded in due time by his son JOHN (born 27th November 1778), a

minor of fifteen at his father's death, who was for a short time associated as partner with his father's shopman, Mr Highley. One of the earliest hits of John the second was Mrs Rundell's Cookery-book, of which over 300,000 copies were sold. He became connected with Mr Stratford Canning, afterwards Lord Stratford de Redcliffe, through the assistance he lent him and other Etonians with their publication of *The Miniature*. In 1808-9 he projected the *Quarterly Review*, a Tory organ, in opposition to the Whig *Edinburgh Review*; his first step being to obtain Canning's countenance. A severe criticism of Scott's *Marmion* in the *Edinburgh Review* suggested to Murray a visit to Scott; he secured his co-operation, as also that of Heber, Canning, George Ellis, and Sir John Barrow. The first number was published February 1, 1809, under the editorship of William Gifford. The new periodical was completely successful, attaining a circulation of 18,000 copies, and brought Murray into communication not only with the chief literati, but also with the Conservative statesmen of the time. A still more fortunate connection was that with Lord Byron (1810), whom he offered £600 for the first two cantos of *Childe Harold* (published 1812). Murray now removed from Fleet Street to Albemarle Street, where the business is still carried on. Here Byron and Scott first met, and here Southey made the acquaintance of Crabbe. Almost all the literary magnates of the day were 'four o'clock visitors' in Albemarle Street—'wits and bards; Crabbes, Campbells, Crokers, Freres, and Wards.' Murray paid Byron nearly £20,000 for his works, and his dealings with Crabbe, Moore, Campbell, and Irving were princely. He had at one time dealings with Constable and Ballantyne, but never approved of their methods of business. Hearing that Byron was in difficulties in 1815, he sent him a cheque for £1500, promised another for the same amount, and even offered to sell the copyright of his works on his behalf if necessary. (As to Byron's autobiography, see BYRON.) Perhaps his only unsuccessful venture was the *Representative* (1826) newspaper; his 'Family Library' was begun in 1829, and he issued the travels of Mungo Park, Belzoni, Parry, Franklin, and others. The second John Murray died in his sixty-fifth year, 27th June 1843, and was succeeded by his son, JOHN MURRAY the third, born in 1808, and educated at the Charterhouse and at Edinburgh University. A more practical and realistic age had succeeded that of Byron, and the 'Home and Colonial Library' was the precursor of much of the cheap railway and other literature of the present day. Many of the greatest works in history, biography, travel, art, and science were issued by the third Murray. Among his successes may be mentioned Dr Livingstone's *Travels and Last Journals*, Smiles's *Life of George Stephenson*, *Self-help*, Darwin's works, Sir W. Smith's dictionaries, and the well-known *Handbooks for Travellers* (begun 1836; see GUIDEBOOKS), of the first five of which he was author. He died 2d April 1892. His son, the fourth JOHN MURRAY (born 1851), then became head of the firm, which amalgamated with Smith, Elder, & Co. in 1917. See S. Smiles, *A Publisher and his Friends* (1891), and *John Murray III.*, by John Murray IV. (1919).

Murray, JOHN (1741-1815). See UNIVERSALISM.

Murray, SIR JOHN (1841-1914), born at Cobourg, Ontario, studied in Canada and at Edinburgh University, and, after a voyage on a whaler, was appointed one of the naturalists to the *Challenger Expedition* (1872-76), and successively assistant-editor and editor-in-chief (1882) of the *Reports*. He wrote a *Narrative of the ex-*

pedition and a report on deep-sea deposits, and published innumerable papers on oceanography and biology, fresh-water lakes, &c.

Murray, LINDLEY, grammarian, was born at Swatara, Lancaster county, Pennsylvania, in 1745, the eldest of twelve children, and was educated at a school in Philadelphia belonging to the Society of Friends. On his father's removal to New York he was placed in a counting-house, but his thirst for study was so ardent that he escaped to a school in New Jersey. He then studied law, and was admitted to the bar at the age of twenty-one, and commenced a good practice. During the revolutionary war he engaged in mercantile pursuits with such success as to accumulate a handsome fortune. In 1784, his health failing, he came to England and purchased an estate at Holdgate, near York, where he devoted himself to literary pursuits. In 1787 he published his *Power of Religion on the Mind*, which passed through nineteen editions, and was translated into French. His *Grammar of the English Language* was issued in 1795, and was followed by *English Exercises*, the *Key*, the *English Reader*, *Introduction and Sequel* (both translated into French), a *Spelling Book*, *A First Book for Children*, *A Compendium of Faith and Practice*, and *The Duty and Benefit of a Daily Perusal of the Scriptures*. The lesson-books all passed through numerous large editions, and there can be no stronger indication of how entirely the systematic study of the English language was long neglected by scholars than the fact that Murray's Grammar was for half a century the standard textbook throughout Britain and America. Murray wrote an autobiography to the year 1809, which was published after his death, 16th February 1826.

Murray, THE REGENT. See MORAY.

Murray River, the principal river of Australia, rises in the Australian Alps, flows north-west along the borders of New South Wales and Victoria, and in South Australia passes southward through the shallow Lake Alexandrina towards the sea at Encounter Bay. In its 1600 miles' length it drains 270,000 sq. m. The chief tributaries are the Murrumbidgee and the Darling, themselves large rivers. Under an irrigation scheme, there is at Lake Victoria, 4 miles from the river and 35 below the mouth of the Darling, a large water storage basin, while half a mile below the inflow of the Mitta-Mitta there is the great Hume reservoir, one of the largest in the world. These storage basins, together with a system of locks, are designed also to render navigation continuous throughout the year by averaging out the river's annual flow in flood and drought; but as a valuable waterway the Murray continues to be handicapped by its mouth, which cannot be entered by ships of any size; now, however, its course is tapped at various points by railway. Fruit is the principal product of the Murray valley. See also AUSTRALIA, NEW SOUTH WALES, VICTORIA.

Mürren, a Swiss resort in the Weisse Lütscheline valley, 3 miles S. of Lauterbrunnen.

Murrumbidgee, a river of New South Wales, rises in the Australian Alps, 40 miles from the Pacific coast, flows first northwards through a hilly country, then westwards through great plains, and finally enters the Murray after a course of some 1350 miles. The Lachlan is its principal tributary. Where the river leaves the hills is the Burrinjuck dam, serving the Murrumbidgee irrigation area 240 miles lower down, and regulating also the river's flow for purposes of navigation.

Murshidabad, a town of India, situated on the left bank of the Bhagirathi, a branch of the Ganges, 124 miles N. of Calcutta. During the 18th

century it was the capital of Bengal and a very populous city; but after (1790) the British made Calcutta their headquarters it declined, and the population is now under 11,000. The chief buildings of note are the palace of the Nawab (1837), the Imámbara ('house of prayer'), and a mosque. Two miles south of the city is Motijhil or Pearl Lake; on its bank stood the palace of Suraj-ud-Dowlah, in which the English Residents dwelt. The city is noted for its ivory-carving, its embroidery in gold and silver lace, silk-weaving, and the manufacture of hookah pipes and musical instruments.

Murten, battle. See MORAT.

Murviedro. See SAGUNTUM.

Murzuk. See FEZZAN.

Musa, a genus of Musaceæ (q.v.), to which the Banana (q.v.) belongs, and also Manila Hemp (see ABACA). A very interesting species, *Musa insularimontana*, has been discovered in the mountains of Formosa. Its fruit is full of seeds, and therefore inedible.

Musaceæ, a natural order comprising the largest of herbaceous plants, generally destitute or almost destitute of true stems, yet resembling trees in appearance, and sometimes rivalling palms in stateliness, the long sheathing bases of the leaf-stalks combining to form a false stem. The blade of the leaf has many fine parallel veins proceeding from the mid-rib to the margin. The flowers are congregated on spadices, which are protected by spathes. The fruit is either a 3-valved capsule or fleshy. The species are not numerous; they are natives of warm climates, in which they are widely distributed, and are of great value to the inhabitants of tropical countries; the fruit of some, particularly of the genus *Musa*, being much used for food, whilst the fibres of the leaves are employed for cordage and for textile purposes (see BANANA, ABACA, FIBROUS SUBSTANCES). A very interesting plant of the other Musaceæ is the Traveller's Tree (q.v.) of Madagascar.

Museus, one of the ancient mythical poets, seers, and priests of the Greeks, is said to have been the son of Eumolpus and Selene, or, according to others, the son and pupil of Orpheus. He was the reputed author of a number of poems, oracles, purificatory verses, hymns, &c., of which we possess but a few fragments, and those of doubtful authenticity.—A later MUSEUS, who flourished about the end of the 5th century A.D., was the author of a beautiful little poem in Greek, entitled *Hero and Leander* (ed. by Aldus Manutius c. 1494; by Dilthey, Bonn, 1874; trans. E. E. Sikes, 1920). See HERO.

Musa Ibn Nosair (born 640), the Arab conqueror of northern Africa (699–709) and of Spain (712), fell under the displeasure of the Khalif of Damascus, and died in poverty in the Hejaz in 717.

Musäus, JOHANN KARL AUGUST, a German writer, born on 29th March 1735, at Jena, where he studied theology. In 1763 he was appointed tutor to the pages at the ducal court of Weimar, and in 1770 became professor at the gymnasium. His first production in 1760 was a parody of Richardson's *Sir Charles Grandison*, a book at that time extravagantly admired in Germany. Eighteen years later he satirised Lavater in *Physiognomische Reisen*. But his literary fame rests upon his version of *Volksmärchen der Deutschen*, which professed to be a collection of popular tales noted down from the lips of old people; but such is not exactly the case: their chief note is an artificial naïveté. Nevertheless, they are tinctured with such a blending of satirical humour, quaint fancy, and graceful writing that they have become a

classic of their kind. He continued to work the satirical vein in *Freund Heins Erscheinungen in Holbeins Manier* (1785), and began a course of tales, *Straussfedern* (1787), which he did not live to complete, dying at Weimar, 28th October 1787. See Life by M. Müller (1867) and Ad. Stern in *Literatur-fragmente* (1893).

Muscae Volitantes is the term applied to ocular spectra, which appear like flies on the wing, or floating black spots before the eyes. There are two kinds of muscae volitantes—the one a perfectly harmless kind, while the other is symptomatic of serious disease of the eyes. Whoever will look through a minute pin-hole in a card at the clear sky may see floating before his sight a number of translucent tubes or fibres, and many little beads, of which some are separate, some attached to the tubes, and some apparently within them. Some of the tubes or fibres are straight, others looped or twisted, and others again forked. All these objects are bright in the middle, and bounded by fine black lines, beyond and parallel to which may be seen an appearance of coloured lines or fringes. The doublings and crossings of the loops or knots in the twisted fibres appear as black points. Though the eye be fixed, these bodies change their position with greater or less rapidity. These appearances are produced by the shadows of minute corpuscles and fibres present in the vitreous humour. They are not generally noticed under ordinary conditions; but some persons, especially those who have small pupils or who are short-sighted, readily see them, especially on looking at a bright surface, such as a white cloud or a brightly-illuminated sheet of paper. If attended to and watched they become more prominent, and may cause a good deal of annoyance. When they become visible and troublesome under ordinary conditions they generally indicate some defective state of health, particularly of the digestive organs. The appearance of dark spots before the eyes not answering to the above description generally points to the existence of a diseased condition of the deeper parts of the eye, vitreous humour, retina or choroid: and as these, or the morbid conditions causing them, are almost always visible with the ophthalmoscope, the eyes should be thoroughly examined in any doubtful case (see EYE, OPHTHALMOSCOPE).

Muscardine, or SILKWORM ROT (*Botrytis Bassiana*, so called from the Italian physician Bassi, who first proved its true nature in 1836), is a Discomycete fungus first observed on the silkworm in Piedmont and France in the later part of the 18th century. It was frequently epidemic during the first half of the 19th, but has since been practically stamped out. De Bary showed that it occurs not unfrequently upon a variety of insects.

Muscat, or more correctly MASKAT, capital of Oman (q.v.) or Muscat, stands in a narrow rocky cove shut in by high hills on the Gulf of Oman. Communication with the interior of Arabia is through Matrah, 2 miles up the coast. The town is surrounded by a wall, and defended by forts on the rocky heights above. Its streets are narrow and not over clean; in summer the heat is intense; hence it is not a healthy place. Yet its situation makes it of great importance for the commerce (and smuggling trade) between eastern Arabia, Persia, India, the east coast of Africa, and the Red Sea. Its exports are chiefly dates, limes, and other fruits, cotton goods, hides, mother-of-pearl, pearls, and fish, in which its coastal waters are extraordinarily rich; imports include arms and ammunition (but gun-running is being suppressed), coffee, rice, sugar, piece-goods, &c. Most of the trade is with India. Although a very ancient

place, Maskat remained small until under Portuguese rule (1508-1648) it developed into a prosperous commercial centre. It was subsequently governed by native rulers (*imams*), who succeeded the Portuguese also as masters of Zanzibar and some places on the east coast of Africa. These African possessions were, however, wrested from the imams by a younger branch of the family in 1856. A British Political Agent to advise the Sultan resides at Maskat. Pop. about 10,000.

Muscatel (Ital. *moscado*, 'musk'), the name given to many sweet, strong French and Italian wines, whether white or red. Amongst the finest are the white Rivesaltes and red Bagnol from Roussillon, and the Lunel from the Pyrenees, the Lacrymæ Christi of Naples, &c. Fine varieties are yielded by Syracuse, Sardinia, the Cape, Canary Islands, Corfu, Crete, and Cyprus.

Muscatine, capital of Muscatine county, Iowa, is on the west bank of the Mississippi, built mostly on rocky bluffs, where the river makes a great bend to the south, 211 miles by rail WSW. of Chicago. It has a large trade by river and rail, and contains great canning-works and manufactures of doors, buttons, jewellery, &c. Pop. 16,000.

Muschelkalk (Ger., 'shell-lime'), the middle member of the Triassic system as developed in Germany. It is wanting in Britain. The Muschelkalk consists chiefly of limestone—the series attaining a thickness of 550 to 1100 feet. The upper portion is more or less pure limestone and highly fossiliferous; the middle and lower portions consist mostly of dolomitic limestone, with which are associated rock-salt, gypsum, and anhydrite. One of the most abundant and characteristic fossils of the Muschelkalk is the lily encrinite (*Encrinurus liliiformis*). See TRIASSIC SYSTEM.

Muscle, the fleshy parts of an animal. Muscular tissue is specially distinguished by its power of contracting in one direction, and is the instrument by which all the sensible movements of the animal body are performed. When examined under a high magnifying power the fibres of which it is composed are found to exist under two forms, which can be distinguished from one another by the presence or absence of very close and minute transverse bars or stripes. The fibres of the *voluntary* muscles—those whose movements can be influenced by nerve impulses originated by the will—as well as the fibres of the heart, are *striped*; while those of the *involuntary* muscles, such as the muscular fibres of the intestinal canal, of Blood-vessels (q.v.), and in skin, are *unstriped*.

On examining an ordinary voluntary muscle with the naked eye, we observe that it presents a fibrous appearance, and that the fibres are arranged with great regularity in the direction in which the muscle is to act or contract. On closer examination

Fig. 1.—Attachment of Tendon to Muscular Fibre in the Skate.

it is found that these fibres are arranged in *fasciculi*, or bundles of various sizes, enclosed in sheaths of areolar tissue, by which they are at the same time connected with and isolated from those adjoining them; and when the smallest *fasciculus* visible to the naked eye is examined with the microscope it

is seen to consist of a number of cylindrical fibres lying in a parallel direction, and closely bound together. These fibres may end in blunt extremities or be forked as in the lips, or branched as in the tongue. Each fibre consists of an elastic homogeneous sheath—the *sarcolemma* (Gr. *sarx*, 'flesh,' and *lemma*, 'a skin or husk'), which contains a contractile semi-fluid material. This substance shows transverse striæ at regular intervals, as well as longitudinal striæ. Dilute mineral acids cause the fibre to cleave crosswise into discs. When highly magnified the transverse striæ resolve themselves into (1) a thin dim disc whose edges appear to adhere to the sarcolemma, (2) a clear space, (3) a broad dim disc, (4) a clear space like 2, (5) another disc like 1, &c.

Nerve fibres pierce the sarcolemma, and end upon the contractile substance (see NERVOUS SYSTEM). No blood-vessels penetrate the sarcolemma; they merely lie in the intervals between the fibres. Through the medium of tendon or aponeurosis the muscular fibres are attached to the parts which they are intended to move. Aggregated in parallel series, of greater or lesser size, and associated with nerves, vessels, tendinous structures, &c., they form the various muscles, which are for the most part solid and elongated, but are sometimes expanded (as in the diaphragm) into a membranous shape. In the human subject voluntary muscles are red, and although pale fibres are scattered through many of them, still nothing is ever seen to correspond with what may be found in the muscles of the rabbit. The colour is due to a substance closely akin to the blood-pigment. Each muscle has a middle portion or *belly* and two extremities which are attached. When the belly contracts it acts in a straight line, and drags equally on both extremities; but, as one is more

Fig. 2.—Sarcolemma of Mammalian Muscle.

Fig. 3.—Muscular Fibre of Frog's Tongue—mag. 200 diameters (after Kölliker).

Fig. 4.—Portion of Human Muscular Fibre—mag. 600 diameters.

fixed than the other, the force is spent in bringing the movable attachment nearer to the fixed one, and thus the fixed end is named the *origin*, the movable end the *insertion*. Muscles are usually grouped around joints, and attached to bone.

The *involuntary* or *unstriped* muscular tissue most commonly occurs in the shape of flattened bands of considerable length, but of a width not exceeding $\frac{2}{30}$ or $\frac{1}{30}$ of an inch. Their substance presents fine longitudinal markings, and

each cell possesses an elongated nucleus, towards each end of which a few fine granules are found. Kölliker has shown that every one of these bands or fibres is either a single elongated cell (a fibre-cell) or is a fasciculus of such cells (see CELL). These fibres have not usually fixed points of attachment like the striated fibres, but form continuous investments around cavities within the body, such as the intestinal canal, the blood-vessels; or are dispersed through the substance of tissues, such as the skin, to which they impart a contractile property.

Cardiac muscle, although involuntary, differs in a remarkable manner from the fibres just described. It consists of quadrangular cells, which are often branched at their ends. Each cell has a clear oval nucleus near its centre, and the cells present transverse striæ not so distinct and less regular than those of voluntary muscle. Hitherto these cardiac fibres have not been shown to possess a sarcolemma.

The chemical composition of ordinary or voluntary muscle is described at FLESH. The fibrillæ, or the sarcous elements of which they are composed, consist of a substance termed Syntonin (q.v.), which closely resembles the fibrine or coagulating constituent of the blood; and the same syntonin is also the main constituent of the unstriated muscles, or at all events of their fibre-cells. Like the blood-fibrin, it exists in a fluid form in the living tissue, and only coagulates or solidifies after death.

Muscles vary extremely in their form. In the limbs they are usually of considerable length, surrounding the bones and forming an important protection to the joints; while in the trunk they are flattened and broad, and contribute very essentially to form the walls of

the cavities which they enclose. Muscles derive their names variously (1) from their situation—as the temporal, pectorals, glutæals; or (2) from their direction—as the rectus, obliquus, &c., of which there may be several pairs—as, for example, rectus femoris, rectus capitis; or (3) from their uses—as the masseter, the various flexors, extensors; or (4) from their shape—as the deltoid, trapezius, rhomboid; or (5) from the number of their divisions—as the biceps and triceps; or (6) from their points of attachment—as the sterno-cleido-mastoid, the sterno-thyroid.

The skeleton, which may be termed the locomotive framework, may be regarded as a series of levers, of which the fulcrum is, for the most part, in a joint—viz. at one extremity of a bone—the resistance (or weight) at the

further end, and the force (or muscle) in the intermediate portion. In most cases, in order to preserve the necessary form of the body, muscles are applied at a great mechanical disadvantage as regards the exercise of their power; that is to say, a much larger force is employed than would suffice,

if differently applied, to overcome the resistance. The two main sources of this disadvantage lie in the obliquity of the insertion, and consequently of the action of most muscles, and in the muscles being usually inserted very near the fulcrum. The first of these disadvantages is in many cases diminished by the enlargements of the bones at the joints. See fig. 8, A. The tendons (*i*) of the muscles (*m*) situated above the joint are usually inserted immediately below the bony enlargement, and thus reach the bone that is to be moved (*o*) in a direction somewhat approaching the perpendicular. If this enlargement did not exist (as in Fig. 8, B), the contraction of the muscle, instead of causing the lower bone to turn upon the upper one with comparatively little loss of power, would do little more than cause the two ends of the bones to press upon each other. The second mechanical disadvantage is compensated for by gain in the extent and velocity of movement, and by the avoidance of the great inconvenience of having the muscles extended in straight lines between the ends of jointed continuous levers. Thus, the bones of the forearm (fig. 9, *b, c*) are bent upon the bone of the arm (*a*) by the biceps muscle (*d*), which arises close to the head of the latter, and is inserted at *e*, at a short distance from the elbow-joint, which acts as the fulcrum of the lever (*c*). By this arrangement a contraction of a single inch in the muscle moves the hand (*f*), in the same time, through the extent of about 12 inches, but then the hand moves through every inch with only about the twelfth part of the power exerted by the muscle. By the junction of two or more levers in one direction,

as in the different segments of the extremities, the extent and velocity of their united actions are communicated to the extreme one. Thus, a blow of the fist may be made to include the force of all the muscles engaged in extending the shoulder, elbow, and wrist.

The great and characteristic property of muscular

Fig. 9.

tissue—that of shortening itself in a particular direction when stimulated—is called *contractility*. The stimulus may be direct irritation by mechanical means, or by galvanism, or by some chemical substance, but in the living body the muscular fibres are, in most cases, made to contract by the immediate influence of the nerves distributed among

Fig. 5.

Muscular Fibre-cells from the coat of the Small Intestine (after Quain): *a*, complete cell showing nucleus, intranuclear network and longitudinal fibrillation; *b*, cell broken in process of isolation.

them, which are consequently termed *motor nerves* (see NERVOUS SYSTEM), and are under the influence of the will. By an exertion of volition, we can contract more or fewer muscles at once, and to any degree, within certain limits; and, as a matter of fact, there is hardly any ordinary movement performed in which several muscles are not called into play. But every voluntary muscle is also subject to other influences more powerful in their operation than the will. The movement of the features under the impulses of passion and emotion are more or less involuntary, as is shown by the very partial power the will has of restraining them, and the extreme difficulty of imitating them. Many movements ensue involuntarily when certain impressions, which need not necessarily be attended with consciousness, are made on the surface of the body, or on any part of its interior, either by external or internal causes. Such movements are termed *reflex*, and are noticed in the article NERVOUS SYSTEM. For important groups of muscles, see ARM, EYE, FOOT, HAND, KNEE, LEG, &c.; and for the source of energy, DIET, DIGESTION.

Muscogee, a city of Oklahoma, capital of Muscogee county, near the Arkansas River, is a commercial centre, with petroleum and other manufactures, and several colleges; pop. 30,000.

Muses, originally included amongst the Nymphs, but afterwards regarded as distinct, had the power of inspiring song. They were first honoured amongst the Thracians, and, as Pieria around Olympus was the original seat of that people, it came to be considered as the native country of the Muses, who were therefore called *Pierides*. In the earliest period their number was three, though Homer sometimes speaks of a single muse, and once, at least, alludes to nine. This last is the number given by Hesiod in his *Theogony*, who also mentions their names—Clio, the muse of history; Euterpe, of lyric poetry; Thalia, of comedy; Melpomene, of tragedy; Terpsichore, of choral dance and song; Erato, of erotic poetry; Polyhymnia, of the sublime hymn; Urania, of astronomy; and Calliope, of epic poetry. Their origin is differently given, but the most widely-spread account represented them as the daughters of Zeus and Mnemosyne. Homer speaks of them as the goddesses of song, and as dwelling on the summit of Olympus. They are also often represented as the companions of Apollo, and as singing while he played upon the lyre at the banquets of the Immortals. Various legends ascribed to them victories in musical competitions, particularly over the Sirens. In the later classic times particular provinces were assigned to them in connection with different departments of literature, science, and the fine arts; but the invocations addressed to them appear to have been, as in the case of modern writers, merely formal imitations of the early poets. Their worship amongst the Romans was a mere imitation of the Greeks, and never became truly national or popular. Among the places sacred to them were the fountains of Aganippe and Hippocrene on Mount Helicon, and the Castalian spring on Mount Parnassus.

Museum (Gr. *mousetion*), originally the name given by the ancients to a temple of the Muses, and afterwards to a building devoted to science, learning, and the fine arts. The first museum of this kind was the celebrated Alexandrian Museum—a meeting-place for learned men and a library, founded about 280 B.C. in the palace. After the revival of learning in Europe the term museum came to be applied to collections of antiquities, and sculptures, and paintings. Collections illus-

trative of natural history and other sciences now form a chief part of the treasures of many of the greatest museums, and there are museums devoted to particular branches of science, and to illustrating the industrial arts. Of the museums of Britain, the British Museum (q.v.) and that of South Kensington (see KENSINGTON) are the most important. The museums of the Vatican in Rome, of the Louvre in Paris, of St Petersburg, Dresden, Vienna, Munich, and Berlin, and the National Museum at Washington also are among the greatest in the world. Many Russian and German palaces have been turned into museums since the revolutions. Russian nobles have in many cases stayed on as custodians in their old homes. See books by Sir W. Flower (1898), David Murray (1905), Margaret Jackson (1917), W. Clifford (1923).

Mushroom, or AGARIC, the popular name of a somewhat diverse group of fungi belonging to the Hymenomycetes. The best known of the true mushrooms to English readers is the Common Mushroom (*Agaricus campestris*), the type of the group. In Britain it is the most esteemed of its tribe, though little valued in countries where fungi more generally form an article of diet of the people; in Italy it is disapproved. It should be noted that some of the forms common to Europe and North America are esteemed in England, but found unpalatable in the United States. The Common Mushroom varies in appearance considerably ac-

cording to soil and locality, but presents in all its variations the same essential characters. It has a fleshy head or *pileus*, smooth or scaly on the upper surface, varying in colour from white to different shades of tawny or fuliginous brown. The gills (*hymenium*) on the under side of the head are free, at first pallid, changing by gradations in age to pink, purple, and brown-black. The stem is white, varied in shape, full, firm, furnished towards the top with a white persistent ring. The Common Mushroom is widely distributed in most of the temperate regions of both the northern and the southern hemispheres. In Britain it is abundant chiefly in autumn in pastures and orchards.—The Horse Mushroom (*A. arvensis*) is very frequently found growing in company with the Common Mushroom. It is altogether a coarser and larger form, and is less favoured for

culinary purposes except in the making of ketchup. It often attains enormous dimensions; the top is generally smooth and snow-white, gills brownish white, ultimately with age becoming brown-black, stem pithy or hollow, with a ragged or floccose ring. This is the 'White-caps' Mushroom of some parts of England.—The true St George's Mushroom (*A. gambosus* of some, or *primulosus* of others), so called from appearing about St George's day (April 23), is sometimes confounded with the Common Mushroom. The head is thick and fleshy, at first convex, becoming undulated and irregular in outline, light yellow in colour in the centre, fading to opaque white at the edges, gills yellowish white, irregularly interposed, smaller and larger, overlying each other like the plaits of a frill; the stem is solid, white, when young bulging at the base, but in age either equal throughout or tapering to greater thickness above. The skin of this mushroom is soft and firm to the touch, and in appearance has been aptly described by Berkeley as resembling a cracknel biscuit. It is one of the most prized of the Agarics on the Continent, so much so in Rome that a dish of it is considered the most fitting present to any one whose good offices are to be propitiated.—The Fairy-ring Mush-

Fig. 2.

4. St George's Agaric (*Agaricus georgii*); d, young. 5. Common Mushroom (*A. campestris*); e, young. 6. Fairy-ring Mushroom (*Marasmius Oreades*); f, young. 7. *Clavaria phalloides*; g, young.

room (*Marasmius Oreades*), is common in pastures and in lawns in Britain, and in most parts of Europe. The head is small, smooth, fleshy, convex, having a boss (*umbo*) in the centre, tough, leathery, elastic, wrinkled; when soaked with water brown, when dry buff. The gills are free, distant, somewhat paler than the head; the stem equal in thickness, twisted, tough, fibrous, of a pale silky-white colour. This species is much esteemed by all who know it. Its flavour is extremely fine, and it is employed in the making of the best kinds of ketchup. On the Continent it is dried and used in the form of a powder to flavour various made dishes. Its peculiar mode of growing in circular patches or in rings, which procured for it its popular name, leads to the risk of an allied but poisonous species which sometimes grows in the same manner being confounded with it. This is the False Champignon (*Marasmius urens*), which is readily distinguished from the true Fairy-ring Mushroom by its having a flat top without any boss, and by its narrow gills being closely crowded together. The foregoing

are the most commonly esteemed of edible British mushrooms. But there are a number of others which are not only wholesome but extremely delicate in flavour and nutritious. There is the Parasol Mushroom (*A. procereus*); the Maned Mushroom (*Coprinus comatus*), of which young specimens only should be used; the Red-fleshed Mushroom (*A. rubescens*); the Clouded Mushroom (*A. nebularis*), appearing late in autumn in moist places on the borders of woods; and the Orange-milk Mushroom (*Lactarius deliciosus*). This last is much prized by connoisseurs in edible fungi on the Continent and in Britain. It has, as the name implies, orange-coloured milky sap in the head, and when broken or bruised both the flesh and the milk become green by exposure to the air. This is an excellent test when there is any doubt as to the identity of this and an allied but virulently poisonous species—*L. torminosus*—in which both the flesh and the milk are white, and do not change colour when broken or bruised. Although many of the British fungi are wholesome and nutritious food, yet it is proper that the inexperienced in diagnosing them should be cautioned strongly against eating any species of the wholesome qualities of which they are not absolutely assured. In many continental cities inspectors are appointed to examine all fungi that are brought to market, lest deleterious species should perchance be sold to the people. Those who desire to acquire an accurate knowledge of edible British species of fungi may refer to Dr Badman's *Esculent Funguses* (1863), M. J. Berkeley's *Outlines of British Fungology* (1860), M. C. Cooke's *Edible and Poisonous Fungi* (1894), and other works cited at FUNGI.

The culture of the common mushroom for profit in Britain has since 1875 become an important branch of gardening industry. About London in particular it is entered into by market-gardeners and even by specialists who live and thrive solely by the production of mushrooms for the million. To a lesser extent the industry is also being taken up in the vicinity of the larger provincial towns. In Paris the catacombs are utilised for the growing of mushrooms, as are caves in all parts of France; and in various places disused tunnels have been used for the same purpose. The principles of the culture of mushrooms are very simple, though considerable attention and skill are required in working out the practical details.

Music is an art, and in order to make an impression on our minds it must take as its founda-

Neume Notation of the Tenth Century.

tion the succession of sounds embodied in the scales which we have chosen, and to which we are accustomed; it must also conform to the rules which have become the canon of music. We must look for its birth in Egypt, but it would serve no purpose here to occupy any space with the little that is known of Egyptian, or its offspring Greek music.

It is not improbable that the Israelites took with them to Palestine some songs they had learned in Egypt; and that many of the hymns of the early Christian church were identical with Temple melodies. As from these hymns was formulated the first authoritative musical system, we may say that in a double sense we are indebted to Egypt for the beginning of the modern art. It was St Ambrose towards the close of the 4th century, and Gregory the Great two centuries afterwards, who selected eight scales or 'modes' (the

'Gregorian') as proper for use in church music (see HARMONY), and till about 1600 A.D. the legitimate development of music was in the hands of the clergy. At first a rude system of dots and scratches (*neumes*) above the syllables in the Rubric served to indicate approximately when and how far the voice should be raised or lowered in pitch. This could only have been an aid to memory. The relative pitch of the notes was more definitely shown when a line of normal pitch was drawn through these neumes; and to this line were added three others in order to attain a more exact definition of intervals. The key or clef (*clavis*) was given to this stave of lines by a sign—usually C or F on the line which represented that note (C); sometimes F (f). Later the G (G) clef came into use, of which our treble or violin Clef (q.v.) is a corruption. With the idea of singing in parts instead of unison came the necessity for indicating the relative *duration* of notes as well as their pitch, and for this purpose different shapes were given to the [*Nota*] *Longa* (2)—the *Maxima*

(1) being twice as long—and to the *Brevis* (3) with its supplementary *Semibrevis* (4). A very short note was added—the *Minima* (5). When music came to be printed these signs were made open, and convenience in writing substituted the round form for the square or diamond. The semibreve (S) is now our longest note, although the breve is still to be met in church music, and in the indication of the measure 'two semibreves to the bar' (*Alla Breve*). In order to avoid a certain false relation of sound called the *tritonus*, which the pious old theorists called 'the very devil' ('*Mi contra fa diabolus est in musica*'), some of the church modes used $\text{B}^\flat$ instead of B. This was the only 'license' allowed, and was indicated by the 'B rotundum' (b) instead of the 'B quadratum' (B). These signs are the origin of our 'accidentals'—the flat (b), which lowers the pitch of a note one semitone, and the natural (♮), which restores it. The sharp ($\text{\#}$), which raises the pitch, is also a development of the 'B quadratum.' See also GUIDO ARETINUS, and H.

Counterpoint (1400-1600 A.D.).—Such were the materials with which Johannes Ockenheim or Okeghem (c. 1420-1513) and Josquin des Prés (c. 1450-1521) laid the foundation of Counterpoint (*punctus contra punctum*, 'note against note'), the art of combining one or more melodic parts with a principal melody called the 'Canto Fermo,' or fixed song. Counterpoint was the workshop in which were made many of the best tools used by great musicians of modern times. The art attained its perfection under Orlando di Lasso and Palestrina at the end of the 16th century, just when a new departure by Monteverde became the inauguration of the new school of harmony which was to supersede the old contrapuntal school by assimilating all that was good therein. Other influences which helped to break the monopoly of church counterpoint were the growing popularity and secularity of Madrigals (q.v.), at first distinguishable only by their words from church music; the improvement in organ-building and organ-playing, which encouraged freer part-writing and bolder melodic progressions than the limitations of unsupported human voices allowed; and doubtless also the natural warmth of musical feeling which had found expression among the troubadours of France and the minnesingers of Germany, and in the rude popular songs of these early ages.

Florence Academy.—Most potent factor of all in this new birth of music was the invention (in 1584-1600) of recitative music and the introduction of the dramatic principle by the Florence Academy—a group of literati and artists who met in the house of Count Bardi, a Florentine nobleman. Their aim and ambition was to restore the ancient accompanied Greek play; and by making use of all the slender resources which harmony could then put at their disposal they stumbled, as it were by accident, on the form of recitative, or, as they called it, 'Stilo rappresentativo.' The development of opera and oratorio, with all the various forms of aria, &c., was a natural consequent, a particular account of which will be found under their proper headings.

Monteverde.—The great landmark which separates the old school of counterpoint from the new is the compositions of Monteverde, whose importance is explained in the article on Harmony. It was only gradually that the new leaven spread through the schools of Europe, and nearly one hundred years elapsed between the setting of Palestrina's sun and the appearance of the twin morning-stars of modern music—Bach and Handel. The time, however, was well occupied. In vocal music greater freedom in the use of established forms was gradually attained, and new forms were invented, chief among which was the Aria introduced by Alessandro Scarlatti (1659-1725). He first used the 'second part,' which, followed by a *da capo* or repetition of the first strain, summarised for vocal music the tendency which was dominating all musical development.

The French Grand Opera school, founded by the Florentine Lully (1633-87), studied the art of expressing in sound the most fleeting emotions to be found even in the ever-varying turns of thought in an operatic recitative.

Of still more importance was the progress made during the century in instrumental music. A great impetus to solo-playing in particular, and execution in general, was given by the improvement in the manufacture of violins. The centre of this industry was Cremona, where the three famous families of Stradivarius, Guarnerius, and Amati worked for three generations. Some of their instruments are to-day literally worth more than their weight in gold.

Handel and Bach.—In 1685, on the 23d of February and 18th of March respectively, were born Handel in Halle and Bach in Eisenach. From 1710 till 1739 Handel devoted all his energies and genius to writing operas after the Italian school, and most of his works have shared the fate of their contemporaries and rivals. He was then led into the path of oratorio, and a brilliant succession of well-known compositions sheds an undying radiance on the last twenty years of his active life (see ORATORIO). Bach's influence has been wider and more far-reaching even than that of his great contemporary. Indeed, no less a critical authority than Schumann has declared that music owes as much to Bach as Christianity does to its founder. By virtue of his complete and easy command of all the resources of harmony and counterpoint, his boundless originality and fertility, the invariably high level of his compositions—even when judged by his own high standard—he takes a place above all ancient and modern composers. Under his influence also the German school of composition chose the path of instrumental music, in which the voice is only one of a large orchestra of instruments, entitled to no more consideration than its limits demand. The attempt in Gluck's operas to reconcile the requirements of expressive instrumentation and the demands of the vocal school was more successful in theory than in reality (see GLUCK),

and the true central column of progress has moved up till now in Germany along instrumental lines in the hands of Bach, Mozart, Beethoven, Schumann, Wagner, Strauss, and their contemporaries.

Sonata.—The most important form of instrumental music had hitherto been the Fugue (q.v.), and in its strait and heavy harness these giants of old moved with ease, grace, and dignity. But the age of monothematic work was already past, and the old dance forms (allemande, courante, sarabande, gavotte, gigue) did not readily lend themselves to the requirements of thematic development, so necessary to instrumental music as a conception distinct from music, to which words at once give inspiration and impose limitation. Corelli, A. and D. Scarlatti, Bach, and others each strove to solve the problem in his own way, and the sum of their influences was handed from Emmanuel Bach to the 'formulator of the modern sonata,' Joseph Haydn (1732-1809).

The name 'sonata' was first used in Italy for music which was only to be played or 'sounded,' contrasted with 'cantata,' which was to be sung. The particular form, however, gradually separated itself from all other instrumental music, and when generations of earnest musicians had lavished care, thought, and experience on its development it was accepted, and is accepted, as the form *par excellence*. In its mould are cast sonatas, symphonies, quartets, concertos, &c., and even the most romantic and daring of fantasias find it necessary to recognise its broad and accommodating principles. Haydn's sonatas are still very formal; so also are Mozart's, though he had more in common with the Romantic school of the next century than the elder composer. This is shown by a comparison of their symphonies. Haydn's are beautiful and graceful, but the themes and subjects he chooses are never very deep, nor can they move the depths of the heart. He is most successful in his airy and humorous quick movements. In Mozart's symphonies a nobler and more romantic spirit breathes—sometimes with most intense passion, sometimes with a dignified melancholy. And so the way was prepared for the most powerful and the most widely honoured of all rulers in the realms of sound. In the works which are classed as his 'first period' Beethoven showed how he had studied and mastered the work of his great predecessors. In his second period he proceeded to build on the solid foundation that wonderful structure to which the vast conceptions of his third period form a fitting and glorious crown. Nothing important has been added to sonata form since Beethoven wrote the works between the *Eroica* and Choral Symphonies (1803-23); and although much has since been written, much that is new, much that is original—although a ready appreciation is granted to the passion of Schumann, the romantic power of Schubert, the poetry of Chopin, the refined elegance of Mendelssohn, the successful use of new colour shown in later works by Brahms, Dvořák, Liszt, &c.—Beethoven's sonatas and symphonies still stand unrivalled, unchallenged, whatever the 'symphonic poem' may yet develop into.

Fantasia.—A desire for some more direct, more unfettered expression of feeling not unnaturally succeeded this long striving after adequate form. But, while all great composers devoted most of their genius to its development of perfect form, the growth of the fantasia was much neglected. Only when the greatest minds turned their attention for a moment from the more important aim was anything of lasting importance produced; and that because it is only the mind trained in the strict school of form to use all available resources which can wisely enjoy a liberty so easily converted into license. The earliest attempts in

fantasia form were called 'toccatas' during the 17th century; and, notwithstanding excellent modern toccatas by Schumann, Rheinberger, and others, we may say that the history of the toccata was brought to a close by the magnificent specimens written early in the 18th century by J. S. Bach. The same composer left a freer model than the somewhat formal toccata in one of the most famous and successful fantasias in existence, and instrumental music has never attained nearer to the definiteness of articulate speech than in the great *Chromatic Fantasia*.

The strong romantic movement which naturally ensued after the perfecting of the classical school in Beethoven's hands eagerly followed out the path he so often and with such effect indicated in his works; and, although the name fantasia has lately fallen into much disrepute by reason of many unworthy and worthless compositions, it may recover its fair fame now that Schumann's and Schubert's fantasias have survived their contemporaries. In any case the endless varieties of fantasia (i.e. unfettered) form, and their adoption in rhapsodies, symphonic poems, and the like, have proved as valuable and as potent a factor in modern romantic music as the various modifications they have effected in the classical sonata form (e.g. Liszt's concertos and sonatas). Schumann adopted some very curious whimsical or poetical names for his smaller compositions—nolette, humoreske, carneval, &c.—and the idea has found great favour with many modern writers. The nocturne invented by the Irish pianist Field is more identified with Chopin's dreamy genius. The latter composer also transused the waltz and the polonaise and mazurka of his own unhappy country with such an intensity of passion, such a chivalrous nobility, and surrounded them with such a halo of poetry and romance that they are an important addition to the resources of a modern composer, and Chopin's name overshadows that of Schubert and Weber, earlier workers in the same field (*Deutsche Tänze, L'Invitation à la Valse*). Later developments in instrumental music are intense nationality in colour and thought, as shown in the works of Grieg, Dvořák, Liszt, Mackenzie, Tchaikowski, Sibelius, and a new striving after extended means of expression, as in Strauss, Debussy, Skriabin, Holst.

Vocal Music.—The progress of vocal music from its first great triumph in 16th-century counterpoint was much slower and varied than that of instrumental. The reason of this is not hard to find; for the conception of vocal writing in the contrapuntal school was sound and artistic, and it reached a point of absolute perfection in that epoch called the 'Golden Age.' Thus there was not the necessity for that advance which ever-improving instruments and the feeling for instrumental effects demanded. Indeed, in choral music exactly the same principles which formulated the rules of counterpoint in the 16th century must be recognised by composers of to-day who wish to produce the purest and grandest effects; and the rules themselves have been rather extended in scope than relaxed in meaning by Bach, the most daring choral writer, and his successors. Where the letter of the law has been modified it has been so from within, and the spirit remains the same. It will be convenient here to treat of choral and solo vocal music, leaving other obvious subdivisions to be treated in the articles ORATORIO and OPERA.

Monody.—From the invention of part-singing till the end of the 16th century (i.e. during the course of its legitimate development in the church) vocal music was entirely choral. When a solo was required, the most melodious part was selected from a choral movement, with what must have

been a most unsatisfactory and incomplete result. The first example of a piece conceived and written for one voice seems to have been *Ugolino*, a dramatic scena with viola accompaniment, written (1584) by Galilei (father of the philosopher), one of the Florence Academy. It was this invention of Monody which prepared the way for opera and made it possible. Unfortunately, the first writers in this new school, which aimed after expressive melody, were little proficient in the more solid art of counterpoint which they affected to despise; and this tendency consistently followed out has procured for Italian music its unenviable reputation of being gracefully melodious at the expense of depth and meaning. The rude recitatives of earlier composers became more and more melodious till A. Scarlatti formulated the first *Aria*—i.e. a regular strain of melody, followed by a second in contrast and complement, and thereafter repeated (*Da Capo*). Almost any of Handel's well-known songs will furnish an advanced specimen of this form, which was brought to perfection by Mozart. The more serious style required for religious works, as well as the greater skill in the science of music which was at the disposal of composers like Handel, Bach, and Mozart, saved the *Aria* from its friends, and in northern Europe it chose a slower development but a worthier end. In the schools of Bach, Gluck, Beethoven, Schumann, Wagner, and Strauss the voice is treated as only one instrument, to which indeed the important part is assigned of giving the words intended for illustration—the expression, however, being entrusted to the whole mass of instruments employed. The claims of any settled form to absolute consideration are likewise disregarded where these seem to clash with the higher demands of expression and dramatic truth. Hence the opposition offered and the accusations brought against all these composers in succession by the professional and amateur melodists of each day. None of their styles may be entirely exonerated, but their ideal is certainly the true one, and their work shows a progressive development along at least closely related lines.

Ballads.—Alongside this scientific progress there has always been the popular love of melody which has found expression in folk-song and ballads. Each nation has its characteristics strongly reflected in these, and where they have been recognised and accepted as a veritable and refreshing fount of inspiration—as in Germany, Hungary, and Norway—the gain has been great. They are of course the origin of the simple strophic song or ballad (e.g. Mendelssohn's *Es ist bestimmt*), however skillfully modern composers adorn it with graceful accompaniment (e.g. the same composer's *Auf Flügeln des Gesanges*). The Ballade, which aims at a dramatic setting of some romantic story, is the offspring of the same influence which inspired Weber's operas. In this style Loewe showed Schubert the way, and following composers have used the device very successfully. The art song tries to reflect the most delicate turn of meaning and the deepest subjectivity to be found in the words. It was to a great extent the result of Heine's poetry, and its great exponents, after Schubert, were Schumann and Brahms.

Choral Music.—The chosen home of modern choral music has been Germany and England. In the beginning of the 17th century H. Schütz left his home in Dresden to study the 'new music' of the Florentine school in Italy, and he took the weakling back with him to be reared among the great instrumental masters of Germany. The noble German choral was chosen as a foundation, and in the effort to illustrate the text no device of counterpoint, no resource of the ever-improving science of harmony, was left unused. Graun, Bach, Haydn,

Handel, Mozart, Beethoven, Mendelssohn have enriched the church with innumerable and inestimable treasures in their Passions, Oratorios, Masses, and Psalms; and it is surprising how well fitted the strict writing of all these masters has proved in their hands to convey the most elevated, the most dramatic, the most touching emotions. More modern works are such as Dvořák's *Stabat Mater*, Liszt's Masses, Brahms's *Requiem*, Elgar's *Apostles*, Holst's *Hymn of Jesus*, &c. But the same principle has always commanded the same success; whatever modern development in modern instrumentation, harmony, &c. may be added to a composer's resources, there is only one foundation, that on which the great masters have ever built when rearing their great choral works.

Formal choruses have never been an important part of operatic writing since the first rude beginnings. In plays the single characters will be rather brought together, as it were, than introduced with a distinct intention of giving each an equal part. This feeling for dramatic truth is the origin of the concerted writing in operas—duets, ensembles, finales—the treatment of which is indebted partly to solo vocal writing, partly to choral. The handling of crowds, again, and the best expression in music of their feelings requires different treatment, and it is interesting to compare how each great reformer has approached the problem. Curiously enough, it is the composers who have shown the greatest capacity for many-part writing who have most successfully given the correct impression. No two works are wider asunder than Bach's *Matthew Passion* (1729) and Wagner's *Meistersinger* (1867); and yet it is impossible to deny that the single terrible shout of the multitude 'Barabbas!' and the complicated chorus 'Let Him come down from the cross,' show that a genius in no way inferior to Wagner's, but with comparatively very limited resources, could grapple with the same problem which is so marvellously solved in the street riot scene (*Meistersinger*, act ii.). Gluck's correct feeling saw the difficulty, but his powers were not great enough to overcome it. Mozart's greater, and in this matter somewhat irresponsible, genius never troubled itself on the subject.

Orchestra.—Monteverde laid the foundation of the modern orchestra when he multiplied the stringed instruments and relegated the pianoforte (or rather its precursor the harpsichord) to a somewhat subordinate position. The latter, however, maintained its place in the orchestra till after Handel's day. Between Monteverde and Haydn many experiments were made in the arrangement and combinations of instruments; also in the manufacture of the instruments themselves. By-and-by the various forms of 'Viol' (Viol da Gamba, da Braccio, &c.) resolved themselves into the viola or tenor violin, and the violoncello (i.e. 'the little violone' or smaller double bass). The violin is of course the little viol. And these remain the foundation of our orchestra. The wind-instruments were the flute and the oboe (a compromise among various forms—Oboi d'Amore, di Caccia, &c.), to which the bassoon gave the bass. To these were added trumpets and drums for special effects. Such was the orchestra with which Haydn laid the corner-stone of modern instrumentation. Mozart added the expressive clarinet, which was at once incorporated in the band. The piccolo, or little flute, and the double bassoon (Contra Fagotto) can hardly be called additions in the sense of novelty; and from Mozart's time to Wagner's the improvement, with one important exception, has been in the direction of improvement in mechanism, and in power of variety in combinations and tone colours. The exception is the trombone, first used

with its full effect by Mozart in *Don Giovanni*, and ever becoming more important in the hands of Beethoven, Schubert, Schumann, and Wagner. Berlioz, a great master of instrumentation, embodied the result of his experience in a 'Treatise' which will ever remain one of the greatest monuments of his extraordinary genius. An enumeration of the instruments at Wagner's masterly disposal will show what limitless combinations had become possible. In *Tannhäuser*, the orchestra for which he wrote comprised, besides the usual stringed band (about 12 first violins, 12 second violins, 8 violas, 8 violoncellos, and 6 double basses), 3 flutes, 1 piccolo, 2 oboes, 2 clarinets, 1 bass clarinet, 2 bassoons, 2 horns, 2 valve horns, 3 trumpets, 3 trombones, and 1 bass tuba, with 1 pair of kettle-drums, bass drum, cymbals, triangle, tambourine, and harp; and, on the stage, 4 flutes, 2 piccolos, 4 oboes, 6 corni inglesi, 6 clarinets, 6 bassoons, 12 trumpets, 12 horns, 4 trombones, cymbals, triangle, and tambourine.

Programme Music.—Many attempts of a more or less legitimate kind have been made to illustrate by music alone a certain story, set of scenes, or progress of emotions. Probably the earliest examples which can be pronounced artistically successful are the famous Pastoral Symphony and the sonata *Les Adieux, l'Absence, et le Retour*, by Beethoven. To criticise this tendency would lead us far beyond the limits of this article, and a mere enumeration of names and compositions will suffice to show what an attraction the idea has had for almost all modern composers. Mendelssohn tried to paint Fingal's Cave in an overture, and in his Scotch Symphony he sought to convey the impressions made on him during his visit to Scotland. Schumann painted a whole set of figures and characters in his *Carneval*, and in his great *Fantasia in C* he set out with a very definite intention to convey the meaning of a verse by the poet Schlegel, though for him generally the music called up the picture, not the picture the music. Berlioz went further and proposed to set forth *Episodes in the Life of an Artist* in a symphony. Unfortunately, his morbid and rather gruesome genius chose very repulsive pictures to paint. He entrusted a certain character or sentiment to a certain phrase without words set to the music or a previous explanation. Liszt's and Saint-Saëns's *Symphonic Poems* have been followed by those of Richard Strauss, such as the *Heldenleben*, and the *Sinfonia Domestica* (dealing with a day in the composer's life), the *Don Quixote* variations and *Till Eulenspiegels Lustige Streiche*. Skriabin went further, seeking (in *Prometheus*) to give expression in music to impalpable thoughts that had never been attempted before.

Of course, descriptive music which occurs in the course of a cantata (e.g. in David's *Le Désert* or Berlioz's *Faust*) has the advantage of a definite starting-point in the words which surround and explain it, and therefore is distinct from these words mentioned which aim at dispensing with words except as an inspiration.

Whither music is tending in the 20th century it is difficult to say; but so long as the treasures left us by the great composers are as reverently and as earnestly studied as they are at present: so long as composers recognise that their genius is a call to labour and not to enjoyment: so long as criticism is honest and based upon sound knowledge, there is no fear that the heritage of the ages will be lost. On the other hand, the impulse to break with the rules of the past (as in the past), and set music upon new roads, is strong. Strauss and Reger, Debussy and Ravel have been called impressionists, and the art of Stravinsky, Skriabin, and Schönberg has been compared with that of the post-

impressionists. It is noteworthy that in almost every country in Europe a keenly national spirit is alive, which lovingly studies all available treasures of national music and melody, appreciating it with an insight and breadth only to be obtained in a school of wide and deep musical culture.

Musical Box, a case containing a mechanism which plays tunes automatically. Teeth projecting from a barrel (as in a barrel-organ or a mechanical peal of chimes) impinge on and set vibrating the tongues cut out in *comb* or steel plate; the difference of tone being due to the greater length and breadth of the teeth. The larger and better boxes, some of which play many tunes after one winding up, can be regulated in pace by a fly regulator, with flat wings, which catch the air. The invention dates from the middle of the 18th century. Switzerland (especially Ste Croix) is the chief seat of manufacture.

Musical Glasses. See HARMONICA.

Musical Sand. See SAND.

Musk. The musk of commerce, which is an important element in very many compounded perfumes, is mainly obtained from the Musk-deer (q.v.), the best kind being that known as Chinese musk, and imported from Tonquin. Other kinds are the Indian (from the Himalayas) and the Siberian. Musk is often adulterated with dried blood, bits of leather, &c. In 1890 Bauer of Erfurt produced an artificial musk by treating butyl-toluol with a mixture of sulphuric and nitric acids, the resulting nitro-compound being purified by crystallisation from alcohol.

Musk-deer (*Moschus moschiferus*) is a ruminant Ungulate forming a special family of the Artiodactyla. According to Flower, it represents an ancestral type of the Pecora (Bovidae, Cervidae, Giraffidae), but with nearest affinities to the Deer (Cervidae). As in the Cervidae, the young is spotted, but it has no horns, and the canine teeth of the male project in the form of longish tusks; this latter fact has led to the association of *Moschus* with the Tragulidae (Chevrotains, q.v.), which is, however, not justified by its other characters. The musk-deer is an inhabitant of the mountainous regions of central Asia from the extreme north to as far south as Cochin-China and Nepal. There is only one species, with perhaps four well-marked

varieties. The musk-deer is much hunted on account of the odoriferous secretion which is found in a special gland upon the hinder-part of the abdomen of the males. This substance was first introduced into the west by the Arabs. It is spoken of in the pharmacologies of Serapion and Avicenna and by the traveller Marco Polo. The value of the substance used to be very great, as it figures among the costly objects presented by Saladin to the Greek emperor in 1189. It was used in the embalming of bodies as early as the 14th century. For an interesting account of the musk-deer (and the Chevrotains), see Milne-Edwards, *Annales des Sciences Naturelles* (1864); for the anatomy, Flower, *Proc. Zool. Soc.* 1875; also Lydekker, *The Deer of All Lands* (1898).

Muskegon, capital of Muskegon county, Michigan, is on the Muskegon River, which here (4 miles from its mouth in Lake Michigan) widens into Muskegon Lake, the best harbour on the east side of Lake Michigan. Muskegon has a great lake trade, foundries, machine-shops, and many other important industries. Pop. (1890) 22,702; (1920) 36,570.

Musket. See FIREARMS.

Musk-glands, skin-pits in mammals producing a secretion with a musky odour. They belong to a series of skin-glands, which occur in various parts of the body and with various secretions (see ANAL GLANDS). The most notable musk-glands are those of the male musk-deer and the male beaver. See BEAVER, CASTOREUM, CIVET, &c.

Musk or Muscovy Duck. See DUCK.

Musk-ox (*Ovibos moschatus*) is a member of the family Bovidae. It inhabits at present the most northern parts of the American continent north of lat. 60°. Its remains, which have been found in Quaternary deposits of England, Europe, and Siberia, indicate that it had formerly a much wider range. The hair is long, serving, of course, to protect the animal from the rigour of the climate which prevails in its habitat, and of a brownish colour. The creature measures above 5½ feet from the tip of the nose to the root of the tail, and so approaches in size the smallest Highland cattle. It is gregarious, there being only one or two males to a herd of eighty or a hundred. They browse on grass, reindeer moss, willow shoots, the Labrador tea-plant, and crowberry bushes. The flesh of the calves and cows, when in condition, is very palatable. Unlike that of many purely Arctic

from its fellows, to regain a position of safety by being able readily to detect the whereabouts of the herd than to trust to escape from carnivorous foes by a resemblance in colour to the surrounding snow.

Musk-plants. Various parts of a number of plants smell more or less strongly of musk. Among these are the common little Musk-plant (see MIMULUS) and the Musk-seed (see HIBISCUS). The musk-tree of Jamaica (*Trichilia moschata*), belonging to the Meliaceæ, emits from all parts a smell of musk. All parts of *Guarea grandifolia*, a West Indian tree of the same family, sometimes called musk-wood, also smells strongly of musk. —The drug called Musk-root or Sambul is the root of a plant of the Umbelliferae, and is brought from Persia or central Asia; it has a pure musky odour, and is used as a substitute for musk.

Musk-rat, a name applied to several distinct animals. (1) The Desman (*Myogale*), a genus of insectivorous quadrupeds of the Shrew (q.v.) family (Soricidæ), according to some more nearly allied to the Mole (q.v.) family (Talpidæ), differing from the true Shrews (*Sorex*) in having two very small teeth between the two large incisors of the lower jaw, and the upper incisors flattened and triangular. Behind these incisors are six or seven small teeth (lateral incisors or false canine teeth) and four jagged molars. The muzzle is elongated into a small flexible proboscis. The eyes are very small; there are no external ears; the fur is long, straight, and divergent; the tail long, scaly, and flattened at the sides. The feet have five toes, fully webbed; and the animals are entirely aquatic, inhabiting lakes and rivers, and making holes in the banks, the entrance being under water. *M. pyrenaica*, about 8 inches long, with tail as long as the body, is a native of the streams of the Pyrenees; a larger species (*M. moschata*), very plentiful in the rivers and

Musk-rat, or Desman (*Myogale pyrenaica*).

lakes of the south of Russia, nearly equal in size to the common hedgehog, with tail about three-fourths of the length of the body. The Russian desman is blackish above, whitish beneath; it has long silky hair, with a softer felt beneath, and its fur is held in some esteem. Desman skins, however, are chiefly valued on account of the musky odour which they long exhale, and which is derived from a fatty secretion produced by small follicles under the tail of the animal. The desman feeds on leeches, aquatic larvæ, &c., searching for them in the mud by means of its flexible proboscis. It seldom, if ever, voluntarily leaves the water, except in the interior of its burrows, which are sometimes 20 feet long. (2) The name of Musk-rat is also a common name for an Indian species of Shrew (*Sorex murinus*), in size about equal to the common brown rat, in form and colour much resembling the common shrew of Britain, but remarkable for the powerful musky odour of a secretion which proceeds from glands on its belly and flanks. (3) The name is also given to the Musquash (q.v.).

Musk-ox (*Ovibos moschatus*).

animals—e.g. the Arctic fox—the hair does not become white at the approach of winter. But it has been suggested that this protective change in coloration is not necessary, since it is an animal which lives in herds; hence it is better for an individual, which has got accidentally separated

Muslin, a fine cotton fabric somewhat resembling Gauze (q.v.) in appearance, but it is woven plain without any looping of the warp threads on the weft. A piece of the finest muslin at one time manufactured at Dacca in India, measuring 3 yards in length by 1 in breadth, weighed only the fifth part of an ounce, and cost £40; but none approaching to this in fineness is made in India now. Very fine muslin has been woven from yarn spun by machinery at Manchester, but it wanted the delicate softness of the finest Dacca. Printed muslins are made in France and England for female summer attire. In India some muslins are woven with coloured patterns; others are embroidered with silk or beetles' wings; others again are printed with gold and silver leaf. Such names as 'woven air' and 'evening dew' are given in that country to those of exquisitely fine texture.

Musquash, also called MUSK-RAT, or ONDATRA (*Fiber zibethicus*), a rodent quadruped, a native of North America, from the Rio Grande to the Arctic regions. *Fiber* (or *Neofiber*) *alleni* is a kindred species from Florida. They belong to the family Muridæ, and are allied to our voles. The shape is similar to that of the brown rat; the head and body are about 15 inches in length, the tail 10 inches. The whole body is covered with a short, downy, dark-brown fur, intermixed with longer and coarser hairs. It is a very aquatic animal, seldom wandering from the rivers, lakes, or marshes in which it makes its abode. It is chiefly a vegetable feeder, but like other Muridæ will occasionally take to animal food—e.g. the mollusc *Unio*. The fur is in demand, and forms an article of commerce, skins in large numbers being still exported from America to Britain and other European countries. The musquash burrows in the banks of streams and ponds, the entrances of its burrows being always under water. In marshes the musquash builds a kind of hut, collecting coarse grasses and mud, and raising the fabric from 2 to 4 feet above the water. The flesh of the musquash, at those seasons

Musquash (*Fiber zibethicus*).

when it is fat, is in some request among the American Indians, and is said to be not unpalatable.

Mussel, a name applied to several common bivalves or Lamellibranch molluscs. (1) The Common Sea-mussel (*Mytilus edulis*), very important for bait and not unfrequently used as food, is widely distributed in crowded 'beds' between high and low water marks. It is usually sedentary

and firmly anchored by yellowish silken 'byssus,' but it is also able to shift its quarters and even to climb by slowly extending the range of the byssal thread exuded from the 'foot.' (2) The Horse-mussel (*Modiolus modiola*) is nearly twice as large as the above, and lives a more active burrowing life below the low-water mark. It is never used for food, and is not available for bait. Both these sea-mussels are representative of large genera, and are included in one family—Mytilidæ. (3) Quite different from the above are the fresh-water mussels, Unionidæ, widely distributed in lakes and rivers, where they plough their way slowly along the bottom from one resting-place to another. As good representatives of the Unionidæ, the Pond-mussel, *Anodon cygnea*, the Painter's Mussel, *Unio pictorum*, whose shells were once used for holding water-colour paints, and the Pearl-mussel, *Margaritana margaritifera* (see PEARL), may be noted. For the structure and general characters, see BIVALVES.

The common edible mussel abounds on the Atlantic seaboard of the United States, but is used neither as food nor as bait. In England it is largely used as human food; in Scotland it is not so used, but enormous quantities are required for bait, especially by haddock fishers. The chief objection to mussels as food is that they are occasionally poisonous. Mussels especially which are unhealthy or dead are very apt to contain dangerously poisonous waste-products; care should accordingly be taken that those used for food are thoroughly fresh. A French Commission reported in 1889 that the poison is due to the presence in the mussel of a volatile alkaloid developed under the influence of a particular microbe, which is only found in mussels growing in stagnant and polluted water. Sewage fairly free from the pollution of manufactories is distinctly beneficial to mussel culture. It is said on good authority that mussels lose any poisonous properties they may have if cooked for ten minutes with carbonate of soda.

Musselburgh, an old-fashioned town of Midlothian, near the mouth of the Esk in the Firth of Forth, adjoining Edinburgh. Since 1918 it has been included in Edinburgh parliamentary burgh. The burgh of Musselburgh includes the large fishing-suburb of Fisherrow, and the pretty village of Inveresk, whose conspicuous spired church, rebuilt in 1805 by 'Jupiter' Carlyle, occupies a Roman prætorium. Musselburgh's chief features are its celebrated golf-links and racecourse, Loretto school (marking the site of a famed place of pilgrimage), Pinkie House (1613), the 'Roman' bridge, the quaint tolbooth, and a statue (1853) of David Moir. The manufactures include paper, nets, &c. Pop. (1841) 6366; (1921) 17,110.

Musset, ALFRED DE, was born in Paris, 11th December 1810, the son of an official who rose high in the War Office. He thought first of law, next of medicine, then of art, but at eighteen discovered himself to be a poet, and scarcely a year after published his *Contes d'Espagne et d'Italie*, a collection of unequal poems. A splendid and brilliant youth, of equal grace and assurance, he was warmly received into Victor Hugo's *Cénacle*, the inner shrine of militant Romanticism; was crowned with seductive flatteries by the wider world of society; and in his hunger for premature experience at once flung himself recklessly into the eager pursuit of pleasure in every form. His piece *La Nuit Vénitienne* failed at the Odéon in 1830, and thus turned him from a career in which he was yet to gain triumphs without seeking for them. In 1832 he published *Un Spectacle dans un Fantéuil*, comprising two short plays—*La Coupe et les Lévers* and *À quoi rêvent les Jeunes Filles*, as well as the

poem of *Namouna*, written hastily to eke out a slender volume. Next year followed in the pages of the *Revue des Deux Mondes* two of his very greatest works, the tragical comedies *André del Sarto* and *Les Caprices de Marianne*. It was of Marianne that her creator replied, when asked where he had found her character, 'Nowhere and everywhere; she is not a woman, she is woman.' Next followed the famous poem of *Rolla*, which has not sustained the applause with which it was received. Then came the fatal journey to Italy with George Sand. He first met her in the summer of 1833, and the intimacy quickly blossomed into love. The projected tour was at first opposed by De Musset's mother, but George Sand took the extraordinary step of calling upon her one evening, and in a moment of emotion gained her consent. They set out for Venice at the beginning of winter. About the middle of February his letters to his mother and brother ceased; for six weeks there was silence, then on the 10th April he reappeared alone, broken in health and sunk in the deepest depression of spirits. A quarter of a century later, and soon after his death, she put forth, in the guise of a novel, *Elle et Lui*, her version of the events which led to the catastrophe. Paul de Musset at once retorted with *Lui et Elle* (1859), a book which is poor as fiction, but rings like truth. His account was that she had been grossly unfaithful to De Musset, and that his discovery of this in a state of weak health had brought on an almost fatal attack of brain-fever; she, on the other hand, explained the infidelity as but a delusion of the fever itself. It is at anyrate suspicious that but one of the pair suffered deeply, while the other went on calmly writing romances, and utilising the experience at once as impulse and material. The Jacques Laurent of her story bears many a trait of the true De Musset. Despite, or, more probably, in consequence of his sufferings, the five years that followed his return were his best years of production. Another love quickly followed, only to end as unhappily; and that again was succeeded by a series of unworthy and often sordid entanglements, which distracted his heart and were followed by periods of deep depression which alcohol did little to allay. The patronage of the Duc d'Orléans, the warm friendship of a small circle of devoted friends, and his appointment in 1838 to be librarian at the Home Office did something to take him out of himself, but he was ever as capricious in character as in genius, and the feverish activity that sometimes seized him soon exhausted itself in splendid projects and unfinished poems. Even his famous *Confession d'un Enfant du Siècle* (1835), like most of his works, was begun, laid aside, and then finished under a cloud of sorrow. It is not an autobiography, though it owes its sombre colour to its author's personal experience. It is a striking study of moral pathology, full of admirable expression of cynical contempt for the world and of the misery of hopeless doubt; but, as a work of art, it breaks down pitifully at the close into weakness and platitude. When De Musset's health gave way about 1840 his literary activity began to decline also. He was already, in Heine's phrase, 'a young man who has had a splendid past;' he felt himself an old man at thirty, and to the end he was never blessed with anything of the serenity of the Olympians, nor was he even one of those artists who find consolation in their art. The success of *Un Caprice* at the Théâtre Français in 1847 recalled him for some time to life and hope, but during his last half-dozen years he wrote nothing of importance. He was elected to the Academy, but not without difficulty, in 1852, and Sainte-Beuve has told us of his coming tipsy to its sittings. 'Musset s'absente trop,' said a member on one occasion; 'Il

s'absinthe trop,' was the response. He died of heart disease, 1st May 1857.

Of De Musset's poetry the four pieces entitled *Nuits* mark the highest reach of his lyrical talent. The *Nuit de Mai* and that of *d'Octobre* are perfect and immortal. The *Ode à la Malibran* is a splendid tribute; the famous *Rhin Allemand*, a spirited retort to Nikolaus Becker. He is the poet of a certain range of personal emotions, of youthfulness, and, above all, of passion, in which respect he follows close upon Byron in power, while far surpassing him in unaffectedness and reality, if not always in finish and exquisiteness of art.

His dramatic work is unique in 19th-century literature of its kind for originality, intensity, and variety, linked to brilliant wit and real dramatic genius. It consisted of *comédies*, or regular dramas, full of tragic quality and ending with tragic abruptness, and *proverbes*, the latter short dramatic illustrations of some common saying, such as the bright and charming *Il faut qu'une Porte soit ouverte ou fermée*.

Among his brilliant and inimitable *Nouvelles*, *Le Fils du Titien* is perhaps his finest; of the Contes *Mademoiselle Mimi Pinson* is a masterpiece. His whole work fills but ten small volumes (1876), but it is not too much to say that these include some of the noblest poetry, greatest plays, and best short stories French literature has yet produced.

See the Life by his brother Paul de Musset (3d ed. 1877); studies by C. F. Oliphant (1890), 'Arvède Barine' (1893), Siché (1907), Gauthier-Ferrières (1909), Maurice Donnay (1915).

Mussolini, BENITO, born 29th July 1883 at Predappio (Forlì), organised the Fascist movement and became prime minister of Italy in 1922. See FASCISMO, ITALY (*History*). He is author of *Giovanni Huss* and other works.

Mussooree. See MASURI.

Mussorgski, or MOUSSORGSKY, MODEST PETROVICH, Russian composer, was born at Karevo, in the government of Pskov, in March 1835. He entered the army, but left it in 1857 to give himself to music, under the influence of Balakirev and Dargomijski. For a time he made a living as a government clerk. His opera, *Boris Godunov*, founded upon Pushkin's play, was produced at Petrograd in 1874, and placed him among the foremost masters of the modern Russian school. The latter part of his life was spent in poverty and ill-health; and in Petrograd he died a prey to drugs, 28th March (N.S.) 1881. Besides *Boris Godunov*, he wrote the operas *Khovantchina* (1880; completed by Rimsky-Korsakov), *The Matchmaker*, and *The Fair at Sorochinsk* (unfinished), besides songs, choral and orchestral works, of a markedly Russian character. See studies by Montagu-Nathan (1916), and Calvocoressi (1919).

Mustagh. See KARAKORUM.

Mustang. See HORSE.

Mustapha, a suburb of Algiers (q.v.).

Mustard (*Sinapis*), a genus of Cruciferae, now generally reckoned a sub-genus of Brassica. Three species, all annuals, contribute their seeds to the manufacture of mustard. (1) Black Mustard (*S.*, or *B.*, *nigra*), a native of the middle and the south of Europe, also of Britain, but rare in Scotland; a rather coarse plant, two or more feet high, having the lower leaves lyrate and usually hispid, the upper leaves linear-lanceolate, entire, and hairless. The flowers are yellow, in slender racemes. The pods rarely above half an inch in length, are closely pressed to the stem. The seeds are deep brown. (2) White Mustard (*S.*, or *B.*, *alba*), a native of southern Europe and western Asia, naturalised in the southern parts of Britain and in

Ireland, and in the United States. The whole plant is more or less hairy, the leaves pinnately lobed. The flowers are large compared with those of the preceding species; the pods nearly twice as long, with a long flattened beak, and five prominent nerves; and the seeds are pale yellow. (3) The Wild Mustard (*S. arvensis*, or *B. Sinapis*), also widely known as *Charlock*, is a weed of cultivation only too common throughout Britain and Ireland in cornfields, and in some parts of the United States. Wild mustard is reputed to have yielded the original Durham Mustard, but its seeds are now only gathered for mixing with those of the others. The black mustard is the most pungent, and is almost exclusively used on the Continent. White mustard is favoured in Britain, chiefly because the skin is more easily separated from the seed. The bulk of it is grown in the fens of Lincolnshire and Cambridgeshire, also in Kent and Essex. White mustard is sown in gardens, and used as a small salad. Much of the mustard seed imported from India is *Sarepta Mustard* (*S.*, or *B.*, *juncea*). Mustard is often adulterated (see ADULTERATION); but 'mustard condiment,' made of mustard flour and wheaten flour or starch flour, is less bitter and stinging than pure mustard, and keeps better. Both black and white mustard seed yield by expression a non-drying fixed oil, which is known as *oil of mustard*, and is free from pungency. When the residual cake, possessing in itself little pungent odour, is treated with water it immediately becomes powerfully irritating to the skin. This is due to a chemical action between an albuminous body, myrosin, an enzyme, and complex bodies differing in the two varieties of seed, which are present in the cells. These in presence of water react, giving, in the case of black mustard, a *volatile oil*, having the composition of isothiocyanate of allyl, C_3H_5SCN , while in the white seed the non-volatile sulpho-cyanate of acrynl, C_7H_7SCNO , is produced. This action is similar to that of oil of bitter almonds (see ALMONDS). It is to the formation of these vesicating substances that the pungency and activity of a mustard plaster are due. As the white seed contains more myrosin than the black, it is usual to mix the two, so as to develop fully the action of the latter. The use of boiling water is inadmissible in forming such a poultice, as it destroys the enzyme and rapidly dissipates the volatile oil, on which the virtues partly depend (see BLISTER). 'Mustard papers,' used as vesicants, are made of mustard flour deprived of its fixed oil. The cake that remains after the oil is extracted may be given to cattle as a condiment. —The Mustard-tree of the Bible has been supposed to be *Salvadora persica*, a small tree of the Salvadoraceæ, a small family of doubtful relationship; but other interpreters insist that the ordinary black mustard is meant in the proverb.

Mustelidæ, a family in the bear section of Carnivores (q.v.), somewhat arbitrarily divided into otter-like (Lutrine), badger-like (Meline), and weasel-like (Musteline) sub-families. See the articles on these and related types.

Muta Nzige. See ALBERT-EDWARD NYANZA.

Mutation. See HEREDITY, UMLAUT.

Mute, a small instrument used to modify the sound of the violin or violoncello. It is attached to the bridge by means of a slit, its three legs standing between, but clear of, the strings. The mute softens the tone and imparts to it a peculiar muffled and tremulous quality, which is sometimes very effective. Its application is indicated by the letters *c. s.*, or *con sordino*, and its discontinuance by *s. s.*, or *senza sordino*. A mute, consisting of a pear-shaped pad of leather or other material, is sometimes used for brass instruments.

It is inserted into the bell of the instrument, thereby subduing the sound and producing the effect of great distance. The fist is sometimes used as a substitute. For muffling of the drum, see DRUM. See also DEAF AND DUMB, PHONETICS.

Mutiny, as defined by British military law, is 'collective insubordination,' or the combination of two or more persons to resist or induce others to resist lawful military authority. The punishment laid down in the Army Act of 1881 for this crime and for failing when present to use the utmost effort to suppress it, or, when knowing of a mutiny or intended mutiny, failing to give notice of it to the commanding officer, is death or such less punishment as a court-martial shall award. It may be pointed out that, in view of the above legal definition, one man alone cannot be guilty of mutiny, but may be charged with 'insubordination,' a crime which, in its worst forms, is also punishable by death. On board ship the mutiny of the *Bounty* (see PITCAIRN ISLAND) in 1789 is memorable, and of that on board the *Danaë* frigate in 1800; the great naval mutiny at the Nore (q.v.) in 1797 is dealt with specially. The Indian Mutiny is a common name of the Sepoy rebellion of 1857. See INDIA.

Mutiny Act was an act passed by the British parliament from year to year, to regulate the government of the army. The navy and marines, when serving on a ship in commission, are under Naval Discipline Acts, 1861 and 1866, the successors of Articles of War first enacted under Charles II., which, unlike the Mutiny Act, remained in force for an indefinite time. By the Bill of Rights the maintenance of a standing army in time of peace, unless by consent of parliament, was declared illegal, and from that time the number of troops to be maintained, and the cost of the different branches of the service, have been regulated by an annual vote of the House of Commons. Soldiers, in time of war or rebellion, were always subject to military law; but the occurrence of a mutiny in certain Scottish regiments soon after the Revolution raised the question whether the same law could be enforced in time of peace; and it was decided that, in the absence of any statute to the contrary, a soldier in time of peace was only amenable to the common law: if he deserted, he was only liable for breach of contract; or if he struck his officer, to an indictment for assault. The authority of the legislature became indispensable to the maintenance of discipline; and parliament, from 1689 till 1879, conferred this and other powers in the Mutiny Act, limited in its duration at one time to six months, but latterly to a year. Although it was greatly changed from the form in which it first passed, the annual alterations were slight, and substantially it had a fixed form. The preamble quoting the above declaration from the Bill of Rights added that it was judged necessary that a force of specified strength should be continued, while it gave authority to the sovereign to enact Articles of War for the government of that force. The act specified the persons liable to its provisions, treated of courts-martial, crimes, and punishments, and of military prisons, furlough, Enlistment (q.v.), stoppages, billets, and the conveyance and entertainment of troops. For years prior to 1878 attention had been drawn in parliament and elsewhere to the shortcomings of the act, as well as to those of the Articles of War (q.v.) by which it was accompanied, explained, and amplified. These representations culminated in the appointment of a Parliamentary Committee, which in 1879 presented a Bill to supersede the Mutiny Act, and, like it, to be passed annually as the 'Army Discipline and

Regulation Act.' The Marine Forces when serving on shore were under the Marine Mutiny Act up to 1879; then they were brought under the 'Army Discipline and Regulation Act.' See ARMY (*Army Discipline*).

Muttra, or MATHURÁ, a town of India, in the United Provinces, is situated on the right bank of the Jumna, 30 miles above Agra. For centuries it was a centre of the Buddhist faith, and the surrounding country teems with traditions of Krishna (or Vishnu, q.v.) and his brother Balarama. There are numerous temples and mosques; the river is lined with magnificent flight of stairs, leading down to the bathing-places in the sacred river; large numbers of pilgrims resort to the city on the occasion of its religious festivals; and troops of monkeys and turtles are supported by the charity of the gentle-hearted people. The city has passed through a long series of misfortunes: it was sacked by Mahmud of Ghazni in 1017; its temples were destroyed by a native sultan in 1500, and by Aurungzebe in 1669; and it was plundered by the Afghans in 1756. In 1803 it passed into the hands of the British. Pop. 53,000.—There is another Muttra (or Matra) adjoining Muscat (q.v.).

Muyscas. See COLOMBIA.

Muzaffarnagar, a municipality in the United Provinces of India and capital of a district 80 miles NE. of Delhi by rail; pop. 24,000.

Muzaffarpur, capital of a district in Bihar, 140 miles N. of the Ganges at Patna, has an external college of Patna University; pop. 33,000.

Myall, an Australian tree (*Acacia pendula*) with ashly leaves and the habit of the weeping willow. *A. homalophylla*, whose branches do not droop, is likewise so named. Its wood, whose scent has been compared to those of raspberry jam and violets, is much used for making whip-handles and tobacco-pipes. The wilder tribes, especially in Queensland, are often called Myalls.

Mycalæ, a wooded promontory of ancient Ionia, over against Samos; in the channel between them, Leotychides the Spartan and Xanthippus the Athenian defeated the Persian fleet in 479 B.C.

Mycelium, the vegetative part of fungi which is not concerned in spore-bearing. It may consist simply of a much-elongated cell growing from the spore, or of a chain of cells, but in the majority it is a tissue of interlaced branched filaments or hyphae, loosely united in many moulds, membranous in dry-rot, compact and tuberous in mushrooms. See FUNGI.

Mycenæ, a very ancient city in the north-eastern part of Argolis, in the Peloponnesus, built upon a craggy height, and said to have been founded by Perseus. It was the capital of Agamemnon's kingdom, and was in his time the principal city in Greece. About 468 B.C. it was destroyed by the inhabitants of Argos, and never rose again to anything like its former prosperity. In Strabo's time its ruins alone remained; these are still to be seen in the neighbourhood of Kharvati, and are noble specimens of Cyclopean architecture. The most celebrated are the 'Gate of Lions,' chief entrance to the ancient Acropolis, the beehive tomb called the 'Treasury of Atreus,' the city wall, and a great rambling palace. Several other beehive tombs have been found. Excavations prosecuted at Mycenæ by Dr Schliemann brought to light in 1876 several ancient shaft-tombs, containing architectural fragments, terra-cottas, vases, weapons, gold death-masks (see MASKS) and other ornaments of thin hammered gold. These tombs are surrounded by a ring of upright slabs. Schliemann's excavations at Tiryns and Troy, the work of Tsountas and of Wace at Mycenæ,

and especially the explorations of Evans and others in Crete, have widened the meaning of 'Mycenæan culture.' Now it is understood to cover a phase of native Ægean or Mediterranean culture, culminating in the Bronze Age, and originally independent, but not untouched by Egyptian, Phœnician, and other influences (see CRETE).

Mycetoma, or MADURA FOOT, a fungoid disease of India akin to Actinomycosis (q.v.). It usually attacks the feet and legs.

Mycetozoa. See MYXOMYCETES.

Mycorrhiza (Greek *mykēs*, fungus, *rhiza*, root), a sheath of fungus threads investing the roots of many forest trees and other plants, and serving the purpose of root-hairs, which are absent where a mycorrhiza is found. The mycorrhiza may be wholly external, or ectotrophic; or it may be endotrophic, penetrating the cells of the root and surrounding the nucleus. The fungus absorbs water, salts, and organic material from the soil, passes them on to the root, and possibly receives useful materials in exchange. A mycorrhiza is most commonly found where there is much humus, and especially on plants that transpire slowly.

Myelitis (Gr. *myelos*, 'marrow') is the term employed to signify inflammation of the substance of the spinal cord. It may be either acute or chronic, but the latter is by far the more common affection. The chronic form begins usually after middle life, with disordered sensations in the extremities, and unusual fatigue after any slight exertion. After a short time paralytic symptoms appear, and slowly increase. The gait becomes uncertain and tottering, and at length the limbs fail to support the body. The paralysis finally affects the bladder and rectum, and the evacuations are discharged involuntarily; and death takes place as the result of exhaustion, or occasionally of asphyxia if the paralysis involves the cervical region of the cord. In the acute form the symptoms are the same as those of the chronic form, but they occur more rapidly and with greater severity, and death sometimes takes place in a few days. Pain may be present in the spine, or in the parts of the body whose nerves proceed from the diseased area of the spinal cord; but it is not usually a prominent symptom when the morbid process begins in the cord itself.

The most common causes of the acute form of this disease are infective disorders, chills and injuries to the back. Syphilis and severe anæmia frequently precede the chronic form, which may also be one of the degenerative signs of old age. It may also result from other diseases of the spine (as caries). The treatment is much the same as that of inflammation elsewhere. When confirmed paralysis has set in there is little to hope for, but in order to prolong life, careful nursing, the prevention of bed-sores, and avoidance of inflammation of the bladder are specially necessary.

Myers, FREDERIC WILLIAM HENRY (1843–1901), son of Frederic Myers (author of four series of *Catholic Thoughts*), was born at Keswick, and passed from Cheltenham to Trinity College, Cambridge, where he became fellow and tutor. From 1872 he was on the permanent staff of school inspectors. He wrote poems and essays, but is chiefly associated with work done in connection with the Society for Psychical Research. Particularly outstanding is his *Human Personality and its Survival of Bodily Death* (1903; abridged by S. B. and L. H. M. 1919). His *Collected Poems with Autographical and Critical Fragments* appeared in 1921, edited by his wife.—His brother ERNEST JAMES MYERS (1844–1921), born at Keswick, educated at Cheltenham and Balliol, was a fellow

of Wadham (1863-83), and was called to the bar (1874) but never practised. He was author of a prose translation of Pindar (1874) and of *Poems* (1877).

Mygale. See BIRD-CATCHING SPIDER.

Myliatta, a Babylonian goddess of fruitfulness, procreation, and birth, in whose honour, according to Herodotus, every girl had once in her life to give herself up to the embraces of a stranger.

Mylodon (Gr. 'grinder-teeth'), a genus of huge fossil sloths, whose remains are found in the Pleistocene deposits of America, associated with the Megatherium and other allied genera. A complete skeleton of the best-known species (*M. robustus*), dug up at Buenos Aires, measured 11 feet from the forepart of the skull to the end of the tail. Another species from the same region was considerably larger. The genus ranged into North America, the remains of one species (*M. Harlani*) having been found in Kentucky. Although like the modern sloth in general structure and dentition, the immense size of *Mylodon* forbids us to suppose that it could have had the same arboreal habits, and the modifications of its structure seems to have fitted it for the uprooting and prostrating of the trees, the foliage of which supplied it with food.

Mymensingh. See MAIMANSINGH.

Myna (*Acridotheres*, or *Gracula* of Cuvier), a genus of birds of the family Sturnidae, of which there are seven species ranging over the whole oriental region and Celebes. The head is more or less crested, and some have a naked space behind and under the eye; the bill is rather short, stout, and compressed; the tail is rounded; the feet are strong, the toes long, and the claws moderately curved. The Common Myna (*A. tristis*), which is found throughout India and extends into Assam and Burma, measures about 10 inches in length, and is of a glossy black colour on the head, neck, and breast; the rest of the plumage is snuff-brown, darkest on the back and wing-coverts, and lightest beneath; the wing-quills are black, with a white spot at their base, forming a conspicuous wing-spot; the tail is black, with a white tip; the bill is deep yellow; and the legs are dull yellow. It is one of the commonest birds of India, where it is found in large numbers, being eminently sociable in its habits. It feeds chiefly on insects, grain, and fruit. It makes its nest in nooks and eaves of houses and in holes in the walls of houses and ruins. The eggs, which usually number four or five, are pale bluish green in colour. It has a variety of notes, some musical and pleasing, others harsh. It is often domesticated, when it becomes pert and familiar, and a good imitator of the human voice, in this respect excelling parrots. This bird was introduced into Mauritius to destroy the grasshoppers, which it did very effectively; but in its turn, when naturalised there, it became a pest through its ravages among fruit trees.—The name Hill Mynas or Grakles (q.v.) is given to four distinct races of birds belonging to the genus *Eulabes* of Cuvier, or *Gracula* of Linnaeus, one from Southern India, another from Ceylon, a third from the Himalayas and Burma, and the last from Malaysia. They are birds of fine glossy plumage with prominent yellow wattles behind the ears. This genus comprises thirteen species found in the oriental region as far as south-west China, Hainan, and Java, and in the Australian region in Flores, New Guinea, and the Solomon Islands. The Australian Mynas or Minahs belong to the genus *Myzantha*, but the Indian Uno is also acclimatised in some Australian towns.

Myopia. See EYE.

Myosin. See GLOBULIN.

Myosotis. See FORGET-ME-NOT.

Myrica. See BOG-MYRTLE, CANDLEBERRY.

Myriopoda (Gr. 'myriad-footed'), a class of terrestrial Arthropods with numerous and very uniform segments. The head is distinct and bears a pair of antennae, while mandibles and maxillae form the true mouth-appendages. The legs themselves have six or seven joints, and end in a claw. Respiration is discharged by air-tubes or tracheae. The class includes two orders, which differ considerably: the Centipedes (Chilopoda), with flattened body, a pair of legs on each ring, the first pair behind the mouth with powerful poison-claws; and the Millipedes (Chilognatha), with cylindrical body, and two pairs of legs on most of the rings. The Centipedes are carnivorous, and their venomous 'bite' is sometimes dangerous; the Millipedes are destructively vegetarian, but otherwise harmless. Generally they avoid the light, and live in the ground, under stones, among moss, under bark, or in similar hidden habitats. Many zoologists would make separate classes of centipedes and millipedes. Fossil forms appear in Carboniferous strata. See CENTIPEDE.

Myristicaceae. See NUTMEG.

Myrmecodia, an Indo-Malayan genus of epiphytic Rubiaceae. A great tuber is formed at the base of the stem, penetrated by many cork-lined galleries and chambers connecting one with another. These are inhabited by ants. The plant seems to utilise their excreta. The kindred genus *Hydnophytum*, found in eastern Asia, New Guinea, and Fiji, is similar.

Myrmecophaga. See ANT-EATER.

Myrmecophily. See ANT, BATSCHIA, CECROPIA, MYRMECODIA.

Myrmidons, the followers of Achilles in the Trojan war. They were an old Thessalian race who colonised the island of Ægina. According to Greek legend, Zeus peopled Thessaly by transforming the ants into men (*myrmæx* = 'an ant').

Myrobalans, the astringent fruit of certain species of Terminalia, trees of the natural order Combretaceae, natives of the mountains of India. *T. Bellerica* produces great part of the myrobalans of commerce of that name; the fruit is about the size of a nutmeg, very astringent, with bitter kernels, to which intoxicating qualities have been ascribed. The bark abounds in a gum, resembling gum-arabic, which is soluble in water and burns away in the flame of a candle. The kernel of the fruit is said to yield an oil which encourages the growth of the hair. Other forms of myrobalans are the Chebulic, the fruit of *T. Chebula*; the Citrine, the fruit of *T. citrina*; and the Indian, which are the small unripe fruits of either or all of the preceding. They are all chiefly in request by tanners, dyers, and ink-makers. Emblic myrobalans, the fruit of *Phyllanthus Emblica*, of the Euphorbiaceae, are similarly used in India-ink. For Myrobalan Plum, see PLUM.

Myron, Greek sculptor, a native of Eleutherae, flourished about 450 B.C. He was a fellow-pupil of Pheidias, and excelled in modelling athletes, animals, and figures in motion. His most celebrated works were the 'Diskobolos,' 'Ladas the Runner,' 'A Cow,' and 'Athene and the Satyr.' Copies have survived of the first and last only. Myron worked principally in bronze.

Myrrh (Heb. *mur*), a gum-resin produced by *Commiphora Myrrha*, a tree of the Burseraceae, growing in Arabia and Somaliland. It is small and scrubby, spiny, with whitish-gray bark, thinly-scattered small leaves, each consisting of three obovate leaflets with obtuse toothlets, and the fruit a smooth brown ovate drupe, somewhat larger than a pea. Myrrh exudes from the bark

gums. It was much used by the ancient Egyptians in embalming. The best myrrh is known in commerce as *Turkey Myrrh*, but practically all myrrh comes either from Aden or from Bombay. The 'myrrh' of Gen. xxxvii. 25, Heb. *lôt*, was probably *Ladanum* (q.v.). See BALSAMODENDRON, BDELLIUM.

Myrsinaceæ, a vast family of chiefly tropical trees and shrubs, the type of which is *Myrsine africana*, a shrub or low tree with some resemblance to the Myrtle, whence the name (Gr. 'myrtle'). It ranges from the Azores, across Africa, Socotra, Arabia, Afghanistan, the Himalaya, into S. China. The family comprises *Maesa*, *Ardisia*, *Embelia*, *Rapanea*, and many other genera, spread over the tropics of both hemispheres, and extending to China and Japan.

Myrtaceæ, a family of dicotyledons, trees and shrubs, natives chiefly of warm, partly of temperate, countries. The family, as defined by the greater number of botanists, includes several sub-families, which are regarded by some as distinct, particularly *Chamelauciaceæ* (in which are contained about fifty known species, mostly beautiful little bushes, often with fragrant leaves, natives of Australia and Tasmania), and *Lecythidaceæ* (two hundred species). Even as restricted, by the separation of these, the order contains about 3000 known species. The leaves are entire, usually with pellucid dots, and a vein running parallel to and near their margin.—Some of the species are gigantic trees, as the *Eucalypti* or Gum Trees of Australia, and different species of *Metrosideros*, of which one is found as far south as the Auckland Islands, in 50½° lat. The timber is generally compact.—Astringency seems to be rather a prevalent property in the order, and the leaves or other parts of some species are used in medicine as astringents and tonics. A fragrant or pungent volatile oil is often present in considerable quantity, of which Oil of *Cajeput* and Oil of *Cloves* are examples. *Cloves* and *Pimento* are amongst the best-known products of the order. The berries of several species are occasionally used as spices in the same way as the true *Pimento*. A considerable number yield pleasant edible fruits, among which are the *Pomegranate*, the *Guava*, species of the genus *Eugenia*, and some species of *myrtle*.

Myrtle (*Myrtus*), a genus of Myrtaceæ, the characteristics of which are well illustrated in the accompanying figure. The Common Myrtle (*M. communis*) is well known as a beautiful evergreen shrub, or a tree of moderate size, with white flowers. It is a native of all the countries around the Mediterranean Sea, and of the temperate parts of Asia, often forming thickets, which sometimes occur even within the reach of the sea-spray. The leaves are ovate or lanceolate, varying much in breadth. They are astringent and aromatic, contain a volatile oil, and were used in medicine by the ancients as a stimulant. The berries are also

Myrtle (*Myrtus communis*):
a, branch in flower; b, vertical section of flower.

aromatic, and are used in medicine in Greece and India. A myrtle wine is also made. Myrtle-bark is used for tanning in many parts of the south of Europe. Among the ancient Greeks the myrtle was sacred to Venus, as the symbol of youth and beauty, was much used in festivals, and was, as it still is, often mentioned in poetry. The myrtle en-

dures the winters of Britain only in the mildest situations in the south. The Small-leaved Myrtle of Peru (*M. microphylla*) has red berries of the size of a pea, of a pleasant flavour and sugary sweetness. Those of the *Luma* (*M. Luma*) are also palatable, and are eaten in Chile. A very humble species of myrtle (*M. nummularia*) spreads over the ground in the Falkland Islands, as thyme does in Britain.

Myrtle-wax. See CANDLEBERRY, WAX.

Mysia, a district of ancient Asia Minor, having the Propontis (Sea of Marmora) on the N., the Ægean on the W., Lydia on the S., and Bithynia and Phrygia on the E. The Troad (see TROY) was one of its subdivisions.

Mysis, a genus of podophthalmous (stalk-eyed) crustaceans, of the order Stomatopoda, much resembling the common shrimps in form.

Mysore, or MAISUR, a state of Southern India, is almost surrounded by districts of the Madras Presidency. The area is 29,500 sq. m. Pop. (1881) 4,186,188; (1921) 5,978,892. Mysore is an extensive tableland much broken by hill-ranges and deep ravines, and is divided into two portions, a little north of 13° N. lat., by the watershed between the Kistna and the Kaveri rivers. Numerous isolated rocks (*drugs*) rising to 4000 or 5000 feet, are a peculiarity of the country, and have been mostly converted into hill-fortresses. The rivers are used for irrigation purposes, but are not navigable. The climate of the higher districts is during a great portion of the year healthy and pleasant. The exports are betel nut and leaves, coffee, ragi, gram, cotton, piece-goods, cardamoms, rice, silk, and sugar. The imports consist mainly of piece-goods, cloth, wheat, silver, gold, cotton,

rice, silk, betel-leaves, and pepper. Gold, a little manganese, and chrome-ore are got. The ruinous misgovernment of the native prince led the British to assume the administration in 1831; but in 1881 Mysore was restored to the native dynasty. The famine years (1876-78) told with great severity on that state. The British headquarters were at Bangalore (q.v.). For history, see HYDER ALI, TIPPOO SAHIB, and INDIA.

The capital of the state, MYSORE, is situated amid picturesque scenery on a declivity formed by two parallel ranges running north and south, 245 miles WSW. of Madras. A prosperous, well-built town, it has broad, regular streets, and substantial houses and public buildings. On the south side stands the fort, which encloses the maharaja's palace; its chief object of interest is a magnificent chair or throne of fig-wood, overlaid with ivory and gold. Pop. (1891) 74,048; (1921) 83,951. The university of Mysore, founded in 1916, has two of its constituent colleges (Maharaja's, Maharani's Women's) in Mysore and two in Bangalore.

Mystagogue (Gr. *mystēs*, 'an initiated person,' and *agō*, 'I lead'), the name in the Greek religious system of the priest whose duty it was to direct the preparations of the candidates for initiation in the several mysteries, as well as to conduct the ceremonial of initiation. The same name is applied in the Christian church as early as the 4th and 5th centuries to the catechists or other clergy who prepared candidates for the Christian *mysteries*, or sacraments, of baptism, confirmation, and the eucharist, especially the last.

Mysteries (Gr. from *myō*, 'I close the lips or eyes'), also called *Teletai*, *Orgia*, or, in Latin, *Initia*, designate certain rites and ceremonies in ancient, chiefly Greek and Roman, religions, only known to, and practised by, congregations of certain initiated men and women, at appointed seasons, and in strict seclusion. The origin, as well as the real purport of these mysteries, which take no unimportant place among the religious festivals of the classical period, and which, in their ever-changing nature, designate various phases of religious development in the antique world, is all but unknown. It does seem, indeed, as if the vague speculations of modern times on the subject were an echo of the manifold interpretations of the various acts of the mysteries given by the priests to the inquiring disciple—according to the lights of the former or the latter. Some investigators, themselves not entirely free from certain mystic influences (like Creuzer and others), have held them to have been a kind of misty orb around a kernel of pure light, the bright rays of which were too strong for the eyes of the multitude; that, in fact, they hid under an outward garb of mummerly a certain portion of the real and eternal truth of religion, the knowledge of which had been derived from some primeval or, perhaps, the Mosaic revelation; if it could not be traced to certain (or uncertain) Egyptian, Indian, or generally eastern sources. To this kind of hazy talk, however (which we only mention because it is still repeated every now and then), the real and thorough investigations begun by Lobeck, and still pursued by many competent scholars in our own day, have, or ought to have, put an end. There cannot be anything more alien to the whole spirit of Greek and Roman antiquity than a hiding of abstract truths and occult wisdom under rites and formulas, songs and dances; and, in fact, the mysteries were anything but exclusive, either with respect to sex, age, or rank, in point of initiation. It was only the speculative tendency of later times, when Polytheism was on the wane, that tried to symbolise and allegorise these obscure ceremonies. The very fact of their having to be put down in

later days as public nuisances in Rome herself speaks volumes against the occult wisdom inculcated in secret assemblies of men and women.

How it was that in the best times of Greece these mysteries had such a hold on such large numbers of people is a point about which there need be no mystery. It is perfectly plain. God has at no time left himself without a witness. The Greeks were men; and being men found it impossible to believe that with the death of the body man's life was at an end, or that the sufferings of the innocent met with no reward, the triumph of the wicked with no requital. But the Greeks had no revealed religion, no authoritative teaching on this point. Yet the religious sentiment required some external support for this aspiration, craved some confirmation of this hope. And at the celebration of the mysteries the man or woman whose thoughts were fixed upon the next world found his or her faltering hope strengthened by the sympathy of thousands who were present from the same motives and in the same faith. That this is the secret of the mysteries is indicated partly by the fact that it was the resurrection of various gods which was most prominently set before the eyes of the initiated; and still more by such expressions as that of Pindar, 'Blessed is he who has seen them before he goes below ground;' or of Sophocles, 'Thrice happy they who have been initiated before they die, for theirs is the lot of life, and evil is it with the others;' or of the chorus of the initiated in Aristophanes (*Ran.* 455), 'We alone enjoy the holy light, we, who were initiated and led a life of godliness toward both kin and stranger;' or of the stone record (*Ephem. arch.* 1883), 'To the initiated death is not an evil: it is a gain.'

The mysteries, as such, consisted of purifications, sacrificial offerings, processions, songs, dances, dramatic performances, and the like. The mystic formulas (*Deiknoumena*, *Drōmena*, *Legomena*, the latter including the Liturgies, &c.) were held deep secrets, and could only be communicated to those who had passed the last stage of preparation at the mystagogue's hand. The hold which the nightly secrecy of these meetings, together with their extraordinary worship, must naturally have taken upon minds more fresh and childlike than our advanced ages can boast of was increased by all the mechanical contrivances of the effects of light and sound which the priests could command. Mysterious voices were heard singing, whispering, and sighing all around, lights gleamed in manifold colours from above and below, figures appeared and disappeared; the mimic, the tonic, the plastic—all the arts, in fact, were taxed to their very utmost to make these performances (the nearest approach to which, in this country, is furnished by transformation-scenes, or sensation-dramas in general) as attractive and profitable (to the priests) as could be. As far as we have any knowledge of the plots of these Mysteries as scenic representations, they generally brought the stories of the special gods or goddesses before the spectator—their births, sufferings, deaths, and specially their resurrections. Many were the outward symbols used, of which such as the Phallus, the Thyrsus, Flower Baskets, Mystic Boxes, in connection with special deities, told more or less their own tale, although the meanings supplied by later ages, from the Neoplatonists to our own day, are various, and often very amazing. The most important Mysteries were, in historical times, those of Eleusis and the Thesmophorian, both representing—each from a different point of view—the rape of Persephone, and Demeter's search for her: the Thesmophorian mysteries being also in a manner connected with the Dionysian worship. There were further those

of Zeus of Crete (derived from a very remote period), of Bacchus himself, of Cybele, and Aphrodite—the two latter with reference to the Mystery of Procreation, but celebrated in diametrically opposed ways, the former culminating in the self-mutilation of the worshipper, the latter in prostitution. Further, there were the Mysteries of Orpheus, who in a certain degree was considered the founder of all mysteries. Nor were the other gods and goddesses forgotten: Hera, Minerva, Diana, Hecate, nay, foreign gods like Mithra (q.v.) and the like, had their due secret solemnities all over the classical soil, and whithersoever Greek (and partly Roman) colonists took their Lares and Penates all over the antique world. The Eleusinian mysteries can be traced back to the 7th century B.C. (cf. *Homeric Hymn to Demeter*, l. 473 ff.). In the time of Herodotus as many as 30,000 people attended them (viii. 65); and between 480 and 430 B.C., the period of Athens' highest power and of the Eleusinian mysteries' greatest fame, the number must have been much greater. When, towards the end of the classical periods, the mysteries were no longer secret, but public orgies of the most shameless kind, their days were numbered. The most subtle metaphysicians, allegorise and symbolise as they might, failed in restoring them to primeval dignity. Their influence on St Paul's doctrines and the views of his disciples as to sacraments have attracted attention from theologians.

See Lobeck, *Aglaophamus* (1829); Farnell, *Cults of the Greek States* (iii. 1906); Dyer, *The Gods of Greece* (1891); works on the Eleusinian mysteries by Foucart (1900-14) and Goblet d'Alviella (1903); Jevons, *Introduction to the Study of Religion*; A. B. Cook, *Zeus* (1914).

Mysteries and Miracle-plays were dramas founded on the historical parts of the Old and New Testaments, and the lives of the saints, performed during the middle ages, first in churches, and afterwards in the streets on fixed or movable stages. Mysteries were properly taken from biblical and miracle-plays from legendary subjects, but this distinction in nomenclature was not always strictly adhered to. We have an extant specimen of the religious play of a date prior to the beginning of the middle ages in the *Christos Paschôn*, assigned, somewhat questionably, to Gregory Nazianzen, and written in 4th-century Greek. Next come six Latin plays on subjects connected with the lives of the saints, by Hroswitha (c. 920-968), a nun of Gandersheim, in Saxony, which, though not very artistically constructed, possess considerable dramatic power and interest; they were discovered by Konrad Celtes and by him first published in 1501 at Nuremberg. The performers were at first the clergy and choristers; afterwards any layman might participate. The earliest record of the performance of a miracle-play in England is found in Matthew Paris, who relates that Geoffrey, afterwards Abbot of St Albans, while a secular, exhibited at Dunstable in 1110 the miracle-play of *St Catherine*, and borrowed costs from St Albans to dress his characters. Fitzstephen, in his *Life of Thomas à Becket* (1183), describes with approval the representation in London of the sufferings of the saints and miracles of the confessors. On the establishment of the Corpus Christi festival by Pope Urban IV. in 1264 miracle-plays became one of its adjuncts, and every considerable town had a fraternity for their performance. A 14th-century scrap of a nativity play in French and English survives. Throughout the 15th and following centuries they continued in full force in England, and are mentioned, sometimes approvingly, sometimes disapprovingly, by contemporary writers. Designed at first as a means of religious instruction for the people, they had long before the

Reformation so far departed from their original character as to be mixed up in many instances with buffoonery and irreverence, intentional or unintentional, and to be the means of inducing contempt rather than respect for the church and religion. An example of the degradation of the Mysteries may be seen in the folk-book of Till Eulenspiegel (q.v.). They lingered on after the Reformation, *The Three Kings of Cologne* being performed at Newcastle so late even as 1599. Remarkable collections are the Towneley Mysteries (Surtees Soc. 1836; E.E.T.S. 1897), the Coventry Mysteries (Shak. Soc. 1841), the Chester Plays (Shak. Soc. 1843; E.E.T.S. 1893), and the York Plays (Clar. Press, 1885).

Out of the mysteries and miracle-plays sprang a third class of religious plays, called *Moralities*, in which allegorical personifications of the Virtues and Vices were introduced as *dramatis personæ*. These personages at first took part in the play along with the scriptural or legendary characters, but afterwards entirely superseded them. The oldest known English compositions of this kind are of the time of Henry VI.; they are more elaborate and less interesting than the miracle-plays. Moralities continued in fashion till Elizabeth's time, and were the immediate precursors of the regular drama.

Miracle-plays and mysteries were as popular in France, Germany, Spain, and Italy as in England; and indeed some of the *pastorales* still acted among the Basques (q.v.) are mere survivals. A piece of the kind yet extant, composed in France in the 11th century, is entitled the *Mystery of the Wise and Foolish Virgins*, written partly in Provençal, partly in Latin. A celebrated fraternity, the Confrérie de la Passion, founded in Paris in 1350, had a monopoly for the performance of mysteries and miracle-plays, the exhibition of each of which took several days. Many of these are still extant.

It is a mistake to suppose that the hostility of the Reformers was what suppressed these exhibitions. The fathers of the Reformation showed no unfriendly feeling towards them. Luther is reported to have said that they often did more good and produced more impression than sermons; and Bishop Bale's *Brefe Comedy of Johan Baptyste* (1538) is an onslaught on the friars. The most direct encouragement was given to such plays by the founders of the Swedish Protestant Church, and by the earlier Lutheran bishops, Swedish and Danish. The authorship of one drama of the kind is assigned to Grotius. In England the greatest check they received was from the rise of the secular drama; yet they continued to be occasionally performed in the times of James I. and Charles I., and it is well known that the first sketch of Milton's *Paradise Lost* was a sacred drama, where the opening speech was Satan's Address to the Sun. A degenerate relic of the miracle-play may yet be traced in some remote districts of England, where the story of St George, the dragon, and Beelzebub is rudely represented by the peasantry. Strange to say, it was in the Catholic south of Germany, where these miracle-plays and mysteries had preserved most of their old religious character, that the severest blow was levelled against them. In 1779 a manifesto was issued by the Prince-archbishop of Salzburg, condemning them, and prohibiting their performance, on the ground of their ludicrous mixture of the sacred and the profane, the frequent bad acting in the serious parts, the distraction of the lower orders from more edifying modes of instruction, and the scandal arising from the exposure of sacred subjects to the ridicule of freethinkers. This ecclesiastical denunciation was followed by vigorous measures on the part of the civil authorities in Austria and Bavaria. One exception was made to the general suppression. In 1633 the villagers of

Oberammergau (q.v.), in the Bavarian highlands, on the cessation of a plague which desolated the surrounding country, had vowed to perform every tenth year the Passion of Our Saviour, out of gratitude, and as a means of religious instruction; a vow which had ever since been regularly observed. The pleading of a deputation of Ammergau peasants with Maximilian of Bavaria saved their mystery from the general condemnation, on condition of everything that could offend good taste being expunged. It was then and afterwards somewhat remodelled, and still takes place every ten years. The inhabitants of this secluded village, long noted for their skill in carving in wood and ivory, have a rare union of artistic cultivation with perfect simplicity; the spectacle seems still to be looked on with feelings much like those with which it was originally conceived; the players take part in an act of religious worship; and though swarms of tourists now join themselves to the peasantry of the neighbourhood, the spectacle is largely a solemnity. The players, some 700 in number, are exclusively the villagers, who act their parts with no little dramatic power, and a delicate appreciation of character. The New Testament narrative is closely adhered to; and the acts alternate with *tableaux* from the Old Testament and choral odes. Less elaborate passion plays take place at Köstenberg near Klagenfurt, and at some other places in Germany and Switzerland (e.g. Erl).

See Petit de Julleville, *Histoire du Théâtre en France* (1880-86); A. W. Pollard, *English Miracle-plays, Moralities, and Interludes* (1890; new ed. 1923); E. K. Chambers, *The Medieval Stage* (1903); Creizenach, *Geschichte des Neueren Dramas*; Gayley, *Plays of our Forefathers* (1909); and the books on the Oberammergau passion-play.

Mysticism is not so much a definite system of thought as a tendency of religious feeling, cherished more or less at different periods in most religions by individuals or groups: the essential element being the effort to attain to direct and immediate communion with God or the divine. The tendency appears in the Mysteries (q.v.) of the Greeks, but is more marked in Buddhism, in various Hindu sects, in Sufism, and is the most prominent feature in Neoplatonism and some of the Gnostic systems. But it is more especially to Christian writers of the middle ages that the name of mystics is wont to be given, one of the earliest being Dionysius the Areopagite, followed by Scotus Erigena; and this mode of thought or mood of mind developed itself in opposition both to scholastic intellectualism and exaggerated 'institutionalism.' Among the great Catholic mystics are Bernard of Clairvaux; his contemporaries the Victorines—Hugo, Richard, and Walter of St Victor near Paris; Bonaventura; John of Chur (died 1380); and Thomas à Kempis. The German mystics are specially Meister Eckhart, Suso, Tauler, Ruysbroeck. Aberrant or fanatical forms are found amongst the Fraticelli, Beghards, Beguines, the Brethren of the Free Spirit, the Brethren of the Common Life (to whom Thomas à Kempis belonged), and the Anabaptists. Less theological and more philosophical are Paracelsus, Bruno, Campanella, Jacob Boehme, Schelling, and Swedenborg. In England William Law is a conspicuous example; and some of the Cambridge Platonists like Henry More were to some extent mystical in their religious teaching. Millenarianism has produced several types; from Jansenism sprang the Convulsionaries. In modern Catholicism St Theresa, Fénelon, Madame Guyon, Molinos, the Quietists, and Bourignon may be specially mentioned. Most of the types and representatives of mysticism are discussed in separate articles. The Quaker doctrine of the 'inner light' tends to mysticism;

and the modernist Tyrrell said, The 'Christianity of the future will be mysticism and charity.'

Fleming, *Mysticism in Christianity* (1913); Rudolf Meiner, *Mystics of the Renaissance* (1911); and the Baron von Hügel's work on Catherine of Genoa; German works by Görres (1846), Helfferich (1842), Noack (1853), Preger (1874-93); and for the influence of the Pagan mysteries on the Christian Church, and the Eucharist as a drama of redemption, works by Aurich, Rohde, and Reitzenstein.

Mythology. A myth is a story told about gods or heroes. Mythology is a term sometimes applied to the collected myths of a nation, sometimes to the scientific study of myths. Mythology in the latter sense of the term has for its object not to ascertain why men believe in gods—that is rather the business of the science of religion—but, granted the belief, why men tell these (sometimes extraordinary) stories about them. The first nation to busy itself with this enquiry was the nation whose mythology had the most luxuriant development, the Greeks. From very early times they started their enquiry with the assumption that there must be something behind the myths as known to them—that there was some meaning in a myth. Thus far, they were as regards most myths quite right. The mistake, however, which the Greek philosophers who undertook to recover the original meaning of various myths made was that they imagined the authors of these myths to be, like themselves, philosophers. In other words, they imagined that not only was there a meaning concealed behind myths, but that that meaning had been intentionally concealed, and that myths were the vehicles by which philosophical teaching had been originally conveyed, and in which it might still be detected. Myth was identified with allegory. The particular branch of philosophy supposed to be veiled by mythology depended on the taste of the particular mythologist. Anaxagoras discovered psychological teaching behind the veil; Empedocles found his own theory of the four elements capable of being stated in terms of mythology (see EMPEDOCLES), and he thus effected the first reconciliation between science and religion. And speaking generally, we may say that from that day to this the magic mirror of mythology has never failed to show to every enquirer that which he wished to see in it. The next attempt at interpretation, which also proceeded from Greece, was to strip myth of all that was supernatural and affirm the residuum to be history (see EUHEMERISM, to which article it is only necessary here to add that in the opinion of Gruppe, in *Die griechischen Culte und Mythen* (vol. i. 1887), the work of Euhemerus was not intended as an explanation of mythology, though it was subsequently regarded as such, but was a romance of much the same character as some of Lucian's work or *Gulliver's Travels*). It is interesting to note that in India an independent attempt was made by the Aitihasika school to explain the mythology of the Vedas as history clothed in the garb of the supernatural. The two modes of interpretation already described—the allegorical and the Euhemeristic—continued to be the only methods applied throughout Roman and Christian times to the 19th century, nor can they be said to be wholly extinct even now. At Rome the Stoics, developing systematically what had been rather suggested than definitely formulated by Empedocles, endeavor-

oured to explain all myths as but allegorical descriptions of physical facts. They failed, however, to explain just those myths which most required explanation, the immoral, brutal, and bestial myths, for examples of which we may refer to GREECE (*Ancient Religion*). Their failure was the more remarkable inasmuch as in India the same key had been applied by the native grammarians with considerable apparent success: but we must remember that the science of grammar had been already carried to great perfection in India, and that some of the mythological figures in the Vedas have names which are much more obviously names of nature-powers than is the case in Greek mythology. Inadequate as was the allegorical interpretation of myth, it continued to enjoy an undisputed mastery of the field of investigation in Europe for many centuries. But, as it was sterile to the end, we need here only mention the fact that the latest and most learned form in which it appeared was the *Symbolik und Mythologie der alten Völker* of Creuzer (q.v.), published 1810-12. The effect of the publication of this work was to overthrow the mode of interpretation which it was designed to prove and illustrate. It led to a thorough investigation of the assumptions on which the allegory theory was based; and an era in the history of mythology as a science is marked by the demonstration given by Lobeck in his *Aglaophamus* (1829), of the utter untenability of these assumptions. What is implied in any theory which explains myths as truths conveyed in the form of allegories is the existence of a caste or class of priests or philosophers, possessing a recondite knowledge and teaching it by means of parables. Now the existence of such a class or caste is a matter which requires to be proved, and of which the proof must satisfy the canons of historical criticism. And it may safely be said that there is absolutely no evidence whatever to show that such a class ever existed amongst the Greeks or any other Indo-Germanic nation.

The establishment of this negative conclusion by Lobeck paved the way for the next step forward in the science of mythology. Scholars had hitherto assumed that the authors of myths were men of learning, philosophers. After the exposure of this error, the next step was to recognise the necessity not only of throwing aside our modern, civilised, artificial ideas, but also of endeavouring to see the myths in 'the light in which they presented themselves to the Homeric or Hesiodic audience.' The conviction of this necessity manifests itself, after the time of Lobeck, in Grote, from whom the quotation in the last sentence is made, *Lehrs (Gott, Götter, und Dämonen)*, and Renan (*Études de l'Histoire Religieuse*). Now, if we try to see myths as primitive man saw them, we can hardly doubt that to the Greek of Homer's time or Hesiod's Aphrodite must have presented herself as the ideal of female beauty, Demeter as the perfect type of motherhood, and so on. Thus far it was thought, by Grote and others, possible to go in the way of interpretation: the Greek was at all times characteristically given to anthropomorphism. But to go further and try to explain not only the individual figures of the gods, but the relations in which those figures are represented by myth as standing to each other, was, by a natural reaction against the exploded system of allegorical interpretation, considered to be futile. Primitive man is but a child; he lives in a world of dreams and fancies which are to him as real as the waking world of facts. As for coherence or meaning in what he chose to dream about his gods, you may as well undertake to decide what shapes the clouds have or what words the bells say. The imagination knows no law, or

at the most is subject only to the laws of poetical and æsthetic consistency. It is vain to endeavour to go beyond the myth, or behind it. It is like the curtain of Zeuxis, which was itself the picture. There is nothing behind it. This, as we have said, was a natural reaction, but the pendulum swung too far. No one at the present day would think of denying that in many cases there is something behind the veil—that most myths have a meaning of some kind. Nor would any one now admit that myths possess poetic or æsthetic consistency; on the contrary, one of the problems of scientific mythology is to explain the inconsistency of feeling which is to be found in myths relating to the same subject, to explain, for instance, the repulsive origin attributed by mythology to Aphrodite, the type of feminine beauty, or the amour carried on by Demeter, the ideal of motherhood, in the shape of a mare, with Poseidon.

A partial solution of this problem was afforded by the brothers Grimm (q.v.), whose labours mark a new era in mythology. While collecting their famous fairy tales from the mouths of the people, they were forced to the conclusion that many a tale which had hitherto only been known in a literary form had existed orally long before it had been put on paper or shaped into verse, and the further inference from this became the wide-reaching conclusion that mythology was not, as the allegory theory had falsely taught, the work of the superior few, but the production of the people. It was the way in which the many expressed their religious feeling. It was their only mode of expression, and it was theirs exclusively. The current of mythology, on this theory, flows from the lower strata of society to the upper. Here we have an explanation of the incongruity existing in the myths told of Aphrodite or Demeter, for instance; for myths could not be perpetually retold in one generation after another without being reshaped to suit the changing modes of thought of different generations. But it will be also noticed that, granting that the current of mythology is upwards from below, we are no nearer an answer to the question, Why do men tell the extraordinary stories they do tell about their gods? The quarter, however, in which an answer to this question might be looked for was indicated by Grimm.

One and the same myth may be found, in different forms, amongst different Aryan peoples (see ARYANS, &c.), and although some such myths may have been borrowed by one people from another, just as one language may borrow words from another, still the resemblances between the myths of different Aryan peoples could, like the resemblance between their languages, be only properly accounted for on the supposition that they had been handed down by each separate people from a time when the forefathers of all were united in one home, one tongue, one faith. In fine, the solution of the problem was to be sought in the application of the comparative method to the study of mythology, and in the creation of a comparative mythology of the Aryan peoples. The verification of this hypothesis was supposed to have been effected when it was discovered that the literature of Sanskrit threw the same light on the structure of myths as the language of Sanskrit had thrown on the structure of the Aryan tongues. Comparative mythology may fairly be said to be the creation of two scholars—in Germany Adalbert Kuhn (1812-81), and in England Max-Müller (q.v.). The object of the school founded by them is to trace myths back to Aryan times, to determine their original forms, and, having done this, to show what was their original meaning, and any changes that may have subsequently come over that meaning. Their guiding principle is that in

the Vedas (q.v.) we see Aryan myths in their earliest form—indeed, that we see them in process of making. The conclusion to which they come is that, owing to the defects of language in its earliest stage, the primitive Aryan could only speak of natural objects as living things, and that in consequence he came to believe that all nature was possessed of life. Again, as in language we can only predicate of a subject something which the subject is not, so in myth, primitive man could only express a phenomenon of nature by comparing it with something which it was not—in fact, could only express it by a simile. When in course of time, and owing to the ‘disease of language,’ the meaning of the simile came to be forgotten, what had originally been a very innocent comparison might become a very repulsive myth. For instance, the sun’s relation to the dawn may be likened to that of a husband to his wife, or of a son to his mother; and a myth of incest may be the result.

The reaction against the allegory theory, which was strongest in the time of Grote, had ceased by the time of Max-Müller. According to the comparative mythologists, there is, after all, something behind myth; not, however, an intentionally veiled meaning, but an unintentionally forgotten substratum, a simile originally descriptive of some natural phenomenon. But this school maintaining that myths have a meaning, and that in some cases the meaning is to be found in a metaphorical description of the sun, the dawn, the wind, &c., pushed its mode of interpretation to extremes that caused a revolt amongst mythologists. The earliest insurgent, Mannhardt (1831–89), was content to turn from the Vedas to popular beliefs and folk-tales as the earliest stratum accessible to the comparative mythologist; but a later revoler, Gruppe, rejected the comparative method altogether, and undertook to demonstrate in his second and following volumes that myths have been borrowed by one nation from another, not handed down from the common ancestors of the separate peoples. It seems indeed impossible to deny that, with regard to the importance of Sanskrit, the same mistake has been made by comparative mythologists as was at first made by comparative philologists. The myths of the Vedas form a literary mythology which is nothing like so near to the myth-making stage in the history of a people as are many of the popular traditions of the peasantry of Europe. On the other hand, although Max-Müller and his school were guilty of many offences against the canons of comparative philology in their desire to identify the names of mythological figures, Gruppe undoubtedly went too far in asserting that comparative philology lends no support whatever to the belief that the Aryans possessed any gods at all. Zeus, Aurora, and Agni may safely be said to have been known to the Aryans, and to have been worshipped as deities.

Another series of attacks have been made upon the Kuhn and Müller school on the ground that, if the comparative method is to be applied, it should be applied to the whole of the facts, and not to one particular section of them. In other words, we must not confine ourselves to Aryan myths, but must open our eyes to the fact that nearly every Aryan myth can be paralleled by similar tales from the remotest quarters of the globe. No explanation which explains only a part of the phenomena and leaves other exactly similar phenomena unexplained can possibly be the right explanation. Obviously, therefore, it is impossible to find the key to all the mythologies in any peculiarity of language, for such peculiarity or ‘disease’ would only affect the mythology of the nations speaking that language or family of languages. The mythologist has not only to answer the question why men tell their

extraordinary tales about the gods, but also the question why do they all tell the same sort of story, no matter what race or clime they belong to. The theory that all myths are derived from a common centre, from which they spread in all directions over the face of the earth by borrowing, would explain the similarity in the myths; but, pending the full elaboration of that theory, the field was held by a theory of mythology of which the most distinguished champion in England was Andrew Lang (q.v.). It is, briefly, that myths are survivals from a primitive stage of culture through which all races pass, and in which they much resemble each other. *Ex eisdem eadem.* Primitive man, whether of the Stone Age on this side of the world or on the other, chipped his flint implements in much the same way; and no one, it was argued, thinks of accounting for the resemblance between the implements thus manufactured by any theory of borrowing or of common descent. It is obvious that the same causes acting on the same organisms produce similar results, and this is as true of mental and moral culture as of material culture. Here, too, we have the explanation of the strange nature of many myths; what seems brutal to us does not seem brutal to the savage. There is therefore nothing surprising in the fact that the gods and heroes of the savage are, like himself, savages. Above all, the same problems presented themselves to primitive peoples in all parts of the world, and were solved by the aid of the same analogies. What was the origin of man? of the world? What causes rain? Why does the wind blow? Why does the sun behave as he does? Why are certain customs observed? The answers which commended themselves to primitive man constitute mythology. At the same time there is no reason to believe that primitive man was not as fond of hearing and telling stories as civilised man is of reading novels. And though most myths may be the explanations which were invented to explain what seemed to primitive man to need explanation, some myths probably were from the beginning designed solely for the gratification of the imagination.

Once more, however, the pendulum is swinging. Dr W. H. R. Rivers’s studies in the diffusion of culture have set Professor Elliot Smith, Dr W. J. Perry, and other ethnologists to trace its path. For this school well-nigh everything in the world’s cultures has come from Egypt. Gold-miners, pearl-fishers, and other seekers for ‘Givers of Life’ (see MAGIC), have carried ‘the archaic civilisation’ step by step from land to land across Asia, from island to island across the Pacific, till even the Indians of Ohio practise meaningless rites and tell irrational tales that once had meaning and reason for Egyptians. Myths, it is claimed, arose out of history, out of actual concrete experience, and in their long course drifted away from reality. Thus we come back to something not far removed from Euhemerism.

In addition to the works of Creuzer, Lobeck, Grote, Lehrs, Renan, Grimm, and Gruppe already referred to, see Max-Müller’s various works, and particularly his *Science of Mythology*; Mannhardt, *Wald und Feldkulte*; Schrader, *Prehistoric Antiquities*; E. B. Tylor, *Early History of Mankind and Primitive Culture*; A. Lang, *Myth, Ritual, and Religion*, and *The Making of Religion*; J. G. Mytilene, or MITYLENE. See LESBOS.

Myxœde'ma is the name given to a diseased condition first described by Sir William Gull in 1873. It occurs in adults, generally females, and is characterised by a thickening of the subcutaneous tissue, most noticeable in the face (which becomes enlarged, swollen-looking, and expressionless) and the hands, with a simultaneous dulling of all the faculties and slowing of the movements of the body. A precisely similar condition occurs in many cases where the thyroid gland has been removed for disease. Myxœdema is very slow in its progress. It greatly resembles cretinism, though the mental condition is much less affected. In 1890-91 Horsley and others treated cases successfully by grafting in the thyroid gland of a calf, or by injecting the juice of animal thyroids. Since then remarkable success has been attained by administering to patients the extract of thyroid gland

of calves or sheep by the mouth. The improvement, which is swift and marvellous, lasts only so long as the sufferers continue to take the remedy, which must therefore become a regular article of diet in small quantities.

Myxomycetes, or MYCETOZOA, a class of very simple fungi, living on damp surfaces exposed to air, especially on rotting wood, and feeding on organic debris. They form composite masses or *plasmodia*, in which numerous units are fused, or in rare cases simply combined in close contact. On the margins of such a mass amœboid processes of living matter flow in and out, with streaming internal movement, and the plasmodium spreads towards moisture, food, and warmth, or away from the light. Draught, cold, or scarcity of food produces a dormant encysted stage. At other times part of the plasmodium divides into spores, each enclosed in a coat, which bursts and liberates a swarm spore, sometimes flagellate, always eventually like a little amœba. A number of these minute amœbæ unite to form the plasmodium from which we started. See FUNGI, PROTOZOA; monographs by Lister (1894; revised 1925), Sir Edward and Agnes Fry (1899).

Mzensk, or MTZENSK, a town in the Russian government of Orel, 31 miles NE. of Orel; pop. 10,000.

N

the fourteenth letter of the modern English alphabet, descends from the fourteenth letter of the ancient Semitic alphabet. The name of this letter was *nūn* (preserved unchanged in Hebrew, Syriac, and Arabic, and altered by the Greeks into *nū*), which probably means 'fish,' as the word

has that sense in Syriac. The earliest known form is . The conjecture that the character was

originally a representation of a fish is not wholly impossible, but finds no support in the extant form, which may perhaps be merely a modification of the preceding letter (see M).

The earliest form of the letter in Greek inscriptions was , which by the reversal of the direction of the writing became , afterwards modified

into N. This form was adopted by the Romans, and is preserved in our ordinary printed capital. Our minuscule n and the black-letter capital descend from the Roman cursive form, in which the upper angle was rounded, and the second upright stroke disappeared. In many mediæval MSS., including some that are carefully written, the minuscule *n* and *u* are often indistinguishable, so that the reader has to interpret the ambiguous symbol by the light of the context. The horizontal stroke over a letter, which was originally used to denote the omission of a following *m*, afterwards came to be employed also for *n*. In English it was used for *n* in printed books as late as the second quarter of the 17th century.

The sound normally expressed by the letter has always been the voiced point-nasal consonant, as in *no*. In Latin it was used also for the back or 'guttural' nasal (as in *sing*), which occurred only before the *k* and *g* sounds. It is similarly used in the modern languages written in Roman letters (except French, where the back nasal is wanting). In the later stages of the Germanic languages (including English), a *g* following a nasal in the same syllable ceased to be pronounced, so that *ng* at the end of a syllable now represents the simple back nasal consonant. Thus while this consonant is expressed by *n* in *think*, and also *longer*, *finger* (where the *g* belongs to the second syllable), it is rendered by *ng* in *sing*, *singer*. The front or 'palatal' nasal, which does not exist in English, but somewhat resembles *n* + *y*, is written in Spanish *Ñ*, *ñ*, in Portuguese *nh*, and in French and Italian *gn*. In French and Portuguese the letter *n* is added to a vowel-letter or a vowel-digraph to form a complex symbol for a nasal vowel.

The Roman name of the letter *en* (formed like *ef*: see the article on F) is preserved in the modern languages, but has become disyllabic in Italian (*enne*) and in Spanish (*ene*). The character *Ñ*, *ñ*, which is counted a separate letter in the Spanish alphabet, is named *ene*.

Nabataeans, an Arab people, already known in the 7th century B.C., and possibly identical with the Ishmaelite tribe of Nebaioth. They took possession of the country once known as Edom (q.v.); and in the beginning of the 3d century B.C. they were one of the most powerful amongst the Arab tribes, warlike, with a force of 10,000 fighting men, puritanical (eschewing settled life and wine), nomadic, and busy carriers of merchandise between the East and the West. In 312 B.C. Antigonos, the general of Alexander, made an attack, unsuccessful, upon their desert fastness of Sela or Petra (q.v.). By the 1st century B.C. they had shaped their power into a kingdom. In the time of St Paul their king Aretas IV. Philopatris, who died in 40 A.D. after a reign of forty-eight years, was master of Damascus and Coele-Syria. They were then at the height of their power, and their merchants travelled as far as Puteoli in Italy. They were in antagonism successively to the Syrian monarchs, the Maccabæan rulers of Judea, and the Romans, but eventually acknowledged the supremacy of these last. Nevertheless Trajan, in 105 A.D., captured their stronghold and put an end to their kingdom. Their chief remains are at Petra (the centre of the cult of their god Dusares), and at Hejra in Arabia. The language of their coins and inscriptions is Aramaic. See SEMITES.

Nabha, a Sikh principality under the political control of the Punjab, Cis-Sutlej, to the E. of Patiala and S. of Ludiana; area, 928 sq. m.; pop. 263,000.

Nablus, corrupted from the Greek *Neapolis*, the ancient *Shechem*, a town of Palestine, stands on the highest part of the pass, between Mounts Ebal and Gerizim, that leads from the Mediterranean to the Jordan. In the same valley or gap are Jacob's Well, the Tree of the Sanctuary, and Joseph's grave. At first a Canaanite city, it was destroyed by Abimelech, a son of Gideon the Judge. Here Rehoboam was crowned king of Israel. The place became the religious centre of the Samaritans (q.v.). The Greek city gave birth to Justin Martyr, and suffered much during the Crusades. See Baedeker.

Nabonassar, Nabopolassar, &c. See BABYLONIA.

Nachtigal, GUSTAV (1834-85), German traveller, was born at Eichstedt, between Magdeburg and Wittenberg, studied medicine, and served as army surgeon until 1863, when he went to North Africa, suffering from a chest disease. In 1868, through the influence of Rohlfis, he was selected to carry presents from the king of Prussia to the sultan of Bornu. Starting from Tripoli in 1869, he travelled by way of Fezzan and Tibesti to Bornu, made excursions into Borgu and Bagirmi, and returned by Wadai, Dar-Fûr, Kordofan, and Cairo (1874). This long and successful journey, in the course of which he visited, the first of Europeans, the native states of Tibesti, Borgu, and Wadai, put him in the forefront of modern travellers. His vast collection of most valuable information

was written down in *Sahara und Sudan* (1879-89). In 1884 Nachtigal was commissioned to annex for Germany Togoland, Cameroons, and Lüderitzland. He died on the return journey off Cape Palmas.

Nacre. See PEARL (MOTHER OF).

Nadir (Arabic *nazir*), that point in the heavens which is diametrically opposite to the Zenith (q.v.), so that the zenith, nadir, and centre of the earth are in one straight line. The zenith and nadir form the poles of the Horizon (q.v.).

Nadir Shah of Persia, the Conqueror, belonged to a Turkish tribe, and was born in Khorasan in 1688. He entered the service of the governor of Khorasan, and soon obtained high promotion; but, having been degraded for some offence, he betook himself to a lawless life, and for several years was the daring leader of a band of 3000 robbers, and gradually extended his territorial authority. Persia was at this time ruled by Ashraf, an Afghan, whose grinding tyranny and cruelty produced in the mind of every Persian a deadly hatred of the very name Afghan. Nadir having avowed his intention of expelling the hated race from the country and restoring the old dynasty, numbers flocked to his standard, and Meshed, Herat, and all Khorassan were speedily reduced. Ashraf, signally defeated in several engagements, fled before the avenger, who, with a celerity only equalled by its thoroughness, purged Persia of even the semblance of Afghan domination. The rightful heir, Tamasp, then ascended the throne, and Nadir received for his services the government of the provinces of Khorassan, Mazanderan, Seistan, and Kerman. He was sent against the Turks in 1731, and defeated them at Hamadan; but his sovereign having engaged unsuccessfully the same enemy, Nadir caused him to be put in prison, and elevated his infant son, Abbas III., to the throne in 1732. The death of this puppet, in 1736, opened the way for the elevation of Nadir himself, who was crowned as *Nadir Shah*. He resumed the war with the Turks, and, though totally defeated in the first two battles, turned the tide of fortune in the subsequent campaign. He also conquered Afghanistan, and drove back the invading Uzbeks. Difficulties arose with the Great Mogul, and, his envoy having been murdered at Jelalabad, Nadir ravaged the North-west Provinces, and took Delhi, which he pillaged. With booty to the amount, it was said, of £20,000,000, including the Koh-i-nûr (see DIAMOND), he returned to the west bank of the Indus. He next reduced Bokhara and Khaurezm, restoring to Persia her limits under the golden reign of the Sassanides. From this period his character underwent a sudden change; he became suspicious, avaricious, and tyrannical, and was assassinated 20th June 1747. See H. Maynard's *Nadir Shah* (Stanhope Essay, 1885).

Nadiya, capital of a district in Bengal, on the Bhagirathi River, 63 miles N. of Calcutta; pop. 12,500. It was the residence of the last independent Hindu king of Bengal (till 1203).

Nævius, GNAEUS, with the exception of Livius Andronicus, the earliest of the creators of Latin literature, was born, probably in Campania, about 265 B.C. In his youth he served in the first Punic war, made his first appearance at Rome as a dramatic writer in 235, and continued his activity for thirty years. Of his life we know little, save that he was very decidedly attached to the plebeian party, and in his plays satirised and lampooned the Roman nobles with all the virulence and indiscretion of a hot-blooded impetuous Campanian—that Gascon of ancient Italy. He incurred the especial hostility of the Metelli, and was imprisoned at

their instance, as we learn from a passage in the *Miles Gloriosus* of Plautus. He was ultimately obliged to retire to Utica in Africa, where he died after 204. Besides his dramatic writings, comprising both tragedies and comedies, he wrote an epic poem, *De Bello Punico*, in the old Saturnian metre. His work bore the stamp of the national genius, and its vigour and invention gave pleasure to Cicero and to Horace. Only a few very unimportant fragments are extant, which may be found in editions more or less complete by Vahlen (1854) and Ribbeck, *Scenicae Poesis Romanorum Fragmenta* (2d ed. 1871-73). See also Sellar's *Poets of the Roman Republic*, and Ribbeck, *Die Römische Tragödie* (1875).

Nævus (Lat., 'a mole;' known popularly as *mother-spot* or *birth-mark*) is a congenital mark or growth strictly on a part of the skin. The most frequent form is the *pigmentary nævus*, or *mole*. This may be simply a darker pigmentation of a circumscribed portion of skin; or the pigmented skin may be thickened and rough as well, and is often thickly covered with hair. Moles do not tend to increase, and do not need to be treated unless for the sake of appearance. In that case, removal by cutting out is the most satisfactory method of treatment.

When the name is used without qualification, a *vascular nævus* or overgrowth of capillary blood-vessels is generally meant, and the term is used of such abnormal growths in whatever organ or tissue they occur. The slightest form is sometimes called *port-wine stain*, and is sufficiently described by the name: there is just so much overgrowth as to produce a deep red discoloration, without appreciable swelling of the part affected. Frequently the abnormal tissue forms a distinct tumour, either in the skin, when it is of a dark red colour, or beneath it, when it may sometimes be recognised by a blue or purplish tinge. The most frequent situations of these vascular nævi are the skin and subcutaneous cellular tissue of the face and head; but they may occur elsewhere. The popular belief is that they are caused by the longing of the mother during her pregnancy for a lobster, or strawberry or raspberry, or some other red-coloured article of food, and that the influence of her mind has impressed upon the foetus a more or less vivid image of the thing she longed for; and hence the name of *mother-spot*. Sometimes these tumours waste away spontaneously, and give no trouble; but frequently they increase rapidly, invade the adjacent tissues, and ulcerate or slough, and thus become dangerous to life by hæmorrhage. When these tumours do not show a tendency to increase no treatment is necessary, except to remove the disfigurement. When treatment is desirable many different methods may be employed, according to the form and situation of the tumour: e.g. removal by knife or ligature; coagulation of the contained blood by electrolysis; production of inflammation by application of caustics or, in infants, by vaccination upon the nævus.

Naga is, in Hindu Mythology, the name of deified serpents. Their king is Sesha, the sacred serpent of Vishnu.

Naga Hills, a district of British India, the south-eastern extremity of Assam, with an approximate area of 3000 sq. m. and a pop. of 158,000. It consists of a mountainous region, covered with jungle and forest, the haunt of various wild animals, and is inhabited by the aboriginal Nagas and other semi-savage people, whose incessant raids into the more orderly British provinces occasioned much trouble from 1832 down to 1881. See books on the Nagas by Hodson, Hutton, Mills, and Smith.

Nagana, a cattle disease transmitted by the *Tsetse* (q.v.).

Nagar. See BEDNOR.

Nagasaki, a leading seaport of Kyūshū, Japan, and for more than two centuries the only gate of communication for that empire with the outer world. Its harbour, famous for its beauty, is a narrow inlet about 3 miles in length. Near its head, beside the native town, is the low, fan-shaped island of Deshima, where the Dutch factory was situated. From 1637 to 1859 the Dutch traders were immured in this prison of 250 × 80 yards, the monotony of their lives being varied by the arrival of the yearly ship from Batavia, and the annual journey to Yedo, when presents were made to the Shōgun. Chinese traders were also permitted to carry on a limited trade. In 1859 Nagasaki became one of the five open ports. The great Takashima coal-mine, situated on an island 8 miles seaward of the entrance to the harbour, serves to give importance to Nagasaki as a coaling-station. Nagasaki also possesses a fine dockyard and patent slip. The foreign settlement is situated on the flat land at the east side of the harbour. At the mouth of the harbour is the small island of Pappenberg (Takaboko), from which 300 Christians were said to have been hurled in the frightful persecutions of the 17th century. Pop. 176,000.

Nagina, a town in the United Provinces of India, 48 miles NW. of Moradabad; pop. 19,000.

Nagoya, a city of Honshū Island, Japan, 90 miles by rail ENE. of Kyōto, has a fine castle and a beautiful Buddhist temple. It is one of the most important porcelain centres in Japan, and also manufactures lacquer ware, cotton, silk embroideries, &c. Pop. 430,000.

Nagpur, a city of British India, the seat of administration for the Central Provinces, 520 miles from Bombay by rail. It lies embosomed in trees, has several handsome tanks, gardens, and temples, and extensive suburbs, but is not a healthy city, the mean temperature being 78·7° F. Fine cloth fabrics are woven, and there is an active trade in wheat, salt, spices, and European goods. A university was founded in 1923. Here, on the 26th and 27th November 1817, a British force of 1350 men, commanded by Colonel Scott, defeated a Mahratta army of 18,000 men. Pop. 145,000.—The district of Nagpur has an area of 3834 sq. m. and a pop. of 792,500; the division, 22,700 sq. m. and a pop. of 3,146,000.—Chota Nagpore (q.v.) is a division of Bihar and Orissa.

Nag's Head Consecration, a calumnious legend first circulated by Roman Catholics forty years after the event about the consecration of Archbishop Parker (q.v., 1559) in the most irregular manner in the Nag's Head Tavern, Cheapside.

Nagy Szeben. See HERMANNSTADT.

Nagy Várad. See GROSSWARDEIN.

Nahant, a summer-resort on a small, rocky peninsula of Massachusetts Bay, 12 miles NE. of Boston.

Nahum. The seventh of the twelve minor prophetic books of the Old Testament is inscribed: 'The burden of Nineveh. The book of the vision of Nahum the Elkoshite.' The opening verses speak (i. 2-8) in general terms of the certainty and awfulness of the divine judgment against the enemies of God, and of his unfailing goodness to those who put their trust in him; these principles are then applied (i. 9-15) on the one hand to some power, not yet named, 'that imagineth evil against the Lord;' and, on the other, to Judah (i. 15), who, though now afflicted, is to be afflicted no more. The second chapter

opens with a rapid sketch of a military armament—the red shields, scarlet uniforms, flashing chariots, brandished spears—hurriedly summoned for defensive war; then Nineveh, first named in ii. 8, is seen as a ruined site which an inundation has swept bare, and the great spoil of the 'dwelling of the lions' is indicated rather than described. The subject is continued in the concluding chapter, which predicts for the bloody city, full as it is of lies and rapine, the same fate as has already overtaken 'populous No' (iii. 8) or No-ammon, the Egyptian Thebes. The date of the prophecy must thus be placed somewhere between the fall of Thebes—i.e. not earlier than 663 B.C., and that of Nineveh—i.e. not later than 612 B.C. The explanation of i. 11 as a current allusion to Sennacherib is thus excluded; but most critics, with Wellhausen, translate as a reference to the past ('did not one come forth . . .') the point lying in Sennacherib's miserable failure. The prophecy is written in classical Hebrew, and is characterised by a bold and vivid originality of style, if also by a conciseness sometimes bordering on obscurity; in more than one expression it has been thought that the writer betrays personal acquaintance with Ninevite affairs, and it is conjectured that he may have been either an Israelite of the northern kingdom who in early youth had been deported after the fall of Samaria, or a Judean who had been carried captive along with Manasseh. Of his personal history nothing is actually known; the name, which is not a very common one, reappears in Luke, iii. 25, and in the name of the Galilean Capernaum ('village of Nahum'). He is described as a native of Elkosh, by which perhaps is to be understood the modern El-Kauseh, near Ramah in Upper Galilee, though others think of Al-Kōsh near Mosul, on the left bank of the Tigris, where the grave of the prophet has been shown since the 16th century. Chap. i. shows traces of an acrostic. See further J. M. P. Smith (*Internat. Crit. Comm.*, 1912), with full bibliography, and works mentioned under HOSEA.

Naiadaceæ, a family of Monocotyledons (q.v.) consisting of Aquatic Plants (q.v.), and including at least the genus *Naias*, in which the male flower is simply a single anther, the female a single carpel. Grass-wrack (q.v.) and other Potamogetonaceæ, Aponogetonaceæ, and Juncaginaceæ are by some united with this order.

Naiads. See NYMPHS.

Naihati, a town of Bengal, 23½ miles NW. of Calcutta by rail; pop. 23,000.

Nails are flattened, elastic, horny plates, which are placed as protective coverings on the dorsal surface of the terminal phalanges of the fingers and toes. Each nail consists of a *root*, or part concealed within a fold of the skin; a *body*, or exposed part attached to the surface of the skin; and a free anterior extremity called the *edge*. The skin below the root and body of the nail is termed the *matrix*, from its being the part from which the nail is produced. This is thick, and covered with highly vascular papillæ, and its colour is seen through the transparent horny tissue. Near the root the papillæ are smaller and less vascular; hence the portion of nail corresponding to this part is of a whiter colour; from its form, this portion is termed the *lunula*. It is by the successive growth of new cells at the root and under the body of the nail that it advances forwards, and maintains a due thickness, whilst at the same time its growth in a proper direction is ensured. The chemical composition of the nails is given in the article HORN, to which class of structures they belong. The finger-nails grow at the rate of about two-fifths of a line in a week, while the toe-nails grow more slowly. When a

nail has been removed by violence, or has been thrown off in consequence of the formation of matter (pus) beneath it, a new nail is speedily formed, provided the matrix has not been seriously injured.

There is a very common and troublesome affection popularly known as *ingrowing nail*. Its most usual seat is by the side of the great toe. It does not in reality arise from any alteration of the nail, but from the adjacent soft parts being constantly pressed by the use of tight shoes against its edge. These parts become swollen and inflamed; supuration ensues, and an intensely sensitive ulcer is formed, in which the nail is imbedded. At an early stage the ulcer may be healed by packing strands of lint under the edge of the nail and wearing wide boots to avoid further compression. In obstinate cases it is not unfrequently necessary to remove a portion of the nail.

Nails. The making of nails by hand has been an established manufacture in the Birmingham district for 300 years. Before the successful (but very gradual) introduction of machine-made nails, men, women, and children, to the number of 60,000, were engaged in the industry. They all worked, as nailers who forge nails by hand still do, in small shops or sheds attached to their houses. In 1861, when the number employed at this work had dwindled down to 26,000, nearly one-half were females. After the introduction of slitting mills earlier in the century, which supplied nail-rod of the proper section to nail-makers, the trade became localised in the seats that it thenceforward occupied, and gradually prospered. Iron plates are cut up into nail-rods by a pair of slitting rolls with square grooves on their surface.

In making nails by hand, the nailer heats the end of the nail-rod at his small forge, and brings it into the form of the spike of a nail by a few strokes of his hammer on the anvil. It is then cut to whatever length is wanted on a chisel, leaving it still attached to the rod. Dropping it next into one of two holes in a 'bolster,' and detaching it from the rod, the nailer forms the head from the projecting end by a few more strokes of his hammer, and then the nail is finished. Dies or 'swages' are required for the heads of ornamental nails.

Nail-making machines, used in America since the latter part of the 18th century, are complicated and varied. From a strip of rolled iron plate, which has a single or double ridge along its edge, one form of machine, for example, cuts the nails cross-wise and partially forms the head of each from the ridge at right angles to the spike. These cut pieces or blanks are moulded to the required form between suitable dies, and then other tools come into play to shape and finish the heads. In this process the nails are formed while the iron is heated.

Cut nails are made from strips of cold iron the breadth of which corresponds to the length of the nail, and the fibre of which runs the long way of the nail. In cut nails the production of shank and point is done at the same time, but an

of these is superior to most of the old wrought iron nails.

Cast nails are made for boots and other purposes. When annealed they are almost as tough as wrought nails. Cast nails are also made in brass.

Wire nails, which are of French origin, are made by a machine in which the end of a reel of wire, while held for a moment by cam grippers, receives a blow from a punch to form the head. The wire is then pushed forward the length of a nail and two punches advance to form the point, when a 'knocker-off' throws out the finished nail.

Nails can be made from pieces of tinplate scrap folded fanwise or rolled up. The cutting, crushing, gripping, and heading operations are done by one machine.

Naini Tal, the summer-resort of the lieutenant-governor of the United Provinces of Agra and Oudh, nestles between spurs of the Himalaya, beside a beautiful lake 6350 feet above sea-level, 70 miles N. of Bareilly. By a disastrous landslide here in 1880, 150 lives were lost. There is a military convalescent depot. Pop. (1921) 11,230, but about 6000 more in the season (September).

Nair, a Hindu caste, in Malabar, who have given name to a peculiar system of polygamy. See FAMILY.

Nairn, county town of Nairnshire, and a summer-resort, stands on the west bank of the river Nairn at its mouth in the Moray Firth, 16 miles ENE. of Inverness. Grant the African traveller was a native. Pop. 4500.

Nairne, CAROLINA OLIPHANT, BARONESS, song-writer, was born 16th August 1766 at the 'auld house' of Gask in Perthshire, the third daughter of its Jacobite laird. In 1806 she married her second cousin, Major William Murray Nairne (1757-1830), who in 1824, by reversal of attainder, became the sixth Lord Nairne, and to whom she bore one son, William (1808-37). They settled at Edinburgh, and after her husband's death she lived for three years in Ireland, then for nine on the Continent, returning at last to the new house of Gask—the old one had been pulled down in 1801. There she died, 27th October 1845. Her eighty-seven songs appeared first under the pseudonym 'Mrs Bogan of Bogan' or 'B.B.' in *The Scottish Minstrel* (1821-24), and posthumously as *Lays from Strathearn*. Not a few of them are mere Bowdlerisations of 'indelicate' favourites; but four at least live, and shall live, with the airs to which they are wedded—the exquisite 'Land o' the Leal' (c. 1798), and 'Call'er Herrin', 'The Laird o' Cockpen,' and 'The Auld House.'

See Charles Rogers's *Life and Songs of Lady Nairne* (1869); T. L. Kingston Oliphant's *Jacobite Lairds of Gask* (1870); G. Henderson, *Lady Nairne*.

Nairnshire, the fourth smallest county of Scotland, is washed on the north for 10 miles by the Moray Firth, and elsewhere bounded by Elgin and Inverness shires. Till 1891 it consisted of a main body, with a maximum length of 18 miles, a mean breadth of 11, and an area of 169 sq. m., and also of five detached portions situated in Elgin, Inverness, and Ross shires, which, having a total area of 31 sq. m., were annexed to Nairnshire in 1476, but disjoined therefrom by the Boundary Commissioners in 1891. The chief rivers are the Nairn and the Findhorn, the former rising in Inverness-shire, and flowing 38 miles north-eastward to the Moray Firth. The surface has a generally southward ascent from the fertile and well-wooded 'laich of Moray' near the coast, till at Carn Glas on the southern boundary it attains 2162 feet. Loch Loy ($1\frac{1}{2}$ by $\frac{1}{4}$ mile) is the largest of seven small lakes.

additional operation is necessary if they require to be headed. The annexed diagram shows how these nails are made without waste of material.

Horseshoe-nails, which are formed of the best charcoal iron, proved the most difficult to make by machinery, and hand-made nails still find a market. A very large proportion of cut nails, as well as other kinds, are now made from steel, and the quality

Less than one-fifth of the entire area is in cultivation, more attention being paid to stock than to crops. The chief antiquities are Kilravock (1400) and Cawdor Castle. Pop. (1881) 10,455; (1921) 8790.

Nairobi, capital of the province of Ukamba and of the colony of Kenya, 350 miles inland from Mombasa, on the so-called Uganda railway, is a growing trade centre; pop. 25,000 (3000 Europeans, 8000 Indians).

Naivasha, a town in the colony of Kenya, named from the shallow lake Naivasha, 80 miles E. of Victoria Nyanza, 6500 feet above the sea, but in the same geological 'rift' in which Baringo lies.

Najaf, a holy city of the Shias in Iraq, near the Euphrates, 33 miles SSW. of Hilla. Catacombs occupy about half of the city. Thousands of corpses are sent thither from Persia.

Nakhichevan, an ancient Armenian town in a fertile region near the Aras, 83 miles SE. of Erivan, is said to have been built by Noah's family on emerging from the ark; pop. 9000. The district has been made an autonomous republic within the republic of Azerbaijan.—NAKHITCHEVAN-ON-THE-DON, near Rostof, founded in the province of the Don Cossacks about 1780 by an Armenian colony, has cloth manufactures and a large trade; pop. 55,000.

Nala is a legendary king of ancient India, whose love for Damayanti forms an episode of the Mahābhārata (q.v.).

Namaquas, the principal Hottentot tribe, a pastoral people with predatory habits, partly in Great Namaqualand, north of the Orange River, and partly south of it. Great Namaqualand, or Namaland, extends from the Orange River to Damaraland (q.v.) northwards, and inland to British Bechuanaland. From 1885 a German possession, with the exception of the small British coast territory of Walvisch Bay (q.v.), it has an area estimated at 460,000 sq. m., and forms part of South-West Africa now administered under mandate of the League of Nations by the Union of South Africa. It is mainly a most sterile and barren region, and along a coast-line of upwards of 400 miles does not present a single running stream; but a few little bays along the coast, such as Angra-Pequena (q.v.), Sandwich Harbour, and Walvisch Bay, afford safe anchorages. There has often been war between Namaquas and Hereros (see DAMARALAND). LITTLE NAMAQUALAND is a barren district of the Cape Province south of the Lower Orange River. Much copper is mined here.

Namcha Barwa a mountain (25,445 feet) in Assam, at the base of which the Brahmaputra cuts across the Himalayas.

Names. The systems of name-giving, whether to persons or places, have varied so widely among different peoples and in different ages that it is impossible within the limits of an article to deal satisfactorily with the methods of nomenclature which have from time to time prevailed even among those peoples who have most widely influenced the history of our race. Perhaps this does not matter much in the case of the place-names, for, though we are often curiously interested in the meaning of the names of places which we know personally, there is seldom any such interest in the meaning of place-names of foreign origin, however famous they may be in history. In personal names we are perhaps a little more interested, and no one can study Roman history without speculating why Romans as a rule bear three names, e.g. *Gaius Julius Caesar*, in which the first name, commonly known as the *prænomen*, corresponds roughly to our Christian name, the second or *nomen* to our

surname (more precisely it is the name of the *gens* to which the man belonged), and the third or *cognomen* to our 'additional' or nickname. When the problem is so large and the range of linguistic knowledge required for its illustration is so wide, the most satisfactory method of dealing with it seems to be to make an intensive study of the names derived from one's native language and its immediate cognates, and then, on the foundation of that study, to refer those who wish to deal with other languages to specialist works upon them. That is the plan upon which this article is built, and in the Bibliographies below specialist works upon the Celtic languages are mentioned. For Greek and Latin the best book is Felix Solmsen's *Indogermanische Eigennamen*.

Personal Names.—The general rule in early days was that persons were given but one name. The elements of such names were originally significant, but their significance was soon lost sight of. Many names contain a first element denoting some divine or supernatural power, and were doubtless given in order to secure the protection of those powers for their bearers, e.g. the *Os-* in *Oswald*, a word ultimately identical with the *As-* in the Scandinavian *Asgard*; the *Regin-* or *Reyn-* in *Reginald* and *Reynolds*, with which may be compared *Ragna-* in the Scandinavian *Ragnarök*, 'twilight of the gods'; and *Alf-* in *Alfred*, which is our word *elf*. Animal names are used by themselves and in compounds, and are either of totemistic origin, or were given in the hope that the bearer might have the qualities of the animal in question, e.g. *Wulfheard*, *Eofof* (= boar). Names were, however, usually given for reasons other than their significance. The popularity of great figures in history or heroic story played an important part, as in the use of the names *Offa*, *Hengest*, *Sigemund* (father of the better known *Siegfried*), or *Alfred*. Royal and noble families showed a preference for names containing some particular element, or beginning with some particular letter; thus the West Saxon kings from Cerdic to Cenred bore names alliterating in *c*, while those of the same line from Aethelwulf to Aethelred the Unready alliterate on a vowel, and the first element in the names of all the last-mentioned group is either *Aethel-* or *Ead-*. Sometimes a name was compounded from one element of the father's name and one of the mother's, thus a certain *Wulfstan* was so called because his mother was called *Wulfgyfu* and his father *Eatstan*. That the significance of names was soon lost sight of is clear from the formation of such names, in which the meaning of the elements was quite a matter of chance, and from the existence of a good number of names to which it is impossible to give any satisfactory meaning, e.g. *Botwulf*, literally 'compensation-wolf.' Practically any two recognised name-elements can be put together to form a name, the only important limitation being that the second element of a man or woman's name must be of the masculine or feminine gender according to the sex of the person. Thus no woman's name ends in *-weald*, and no man's in *-thryth*.

Most of the names so far dealt with are di-thematic, and that is the type most common in early days among the Teutonic peoples generally, but there are a number of monothematic ones also, often of obscure origin, e.g. *Drdda*, *Cissa*. Many of these names are of the hypocoristic type, that is, they are shortened forms of other names, used originally as pet-names, but ultimately raised to the rank of full personal names. They are formed in various ways. Thus the first element of a compound name may be taken in almost unchanged form, as in *Ecga* from the names in *Ecg-*, or the

medial consonant of the first element may be doubled, as in *Sigga*, a pet form for *Sigefrith*, or its medial consonants assimilated, as in *Eoppa* from names in *Eorþ*, such as *Eorþwine*, or a new name developed with the final consonant of the first element and the initial consonant of the second, as in *Ulke* from *Ulf-ketill*. Other pet-forms are developed by the use of diminutive suffixes such as *-ic*, *-oc*, *-uc*, *-el*, which may at times cause mutation of the stem vowel, e.g. from *Dudda* we have *Duddel*, *Dudeca*, *Duduc*, *Dyddel*. Occasionally the patronymic suffix *-ing* is used to form fresh names, as in *Lutting* from *Lutt*. There is a much greater wealth of personal names generally in early times than there is of Christian names in our own days, and in Old English the names, so far as they consist of significant words, are entirely of a dignified character.

The Viking settlements from the 9th century onwards brought a large influx of fresh names, many of which were of the same general types as those already described, but they brought in an important new type, viz. the nickname. This is by origin an *eke*- or additional name, descriptive of a person's physical characteristics, character, &c., as in Harold *Fairhair*, Sigrid *the Proud*, and is often abusive, as in Thrand *Squint-eye*, Atti *the Fool*; but in course of time these additional names came to be used as personal names themselves, and it is undoubtedly largely owing to Scandinavian influence that so many names like *Hræfn* (=raven), *Gamel* (=old, our *Gamble*), were in use at the time of the Norman Conquest as personal names. The Vikings also had their share in developing the use of a second name, destined ultimately to develop into the family or surname. We have seen that they often employed a second name of the nickname type. They also freely used second names of the patronymic type, e.g. Harold *Gormson*. In Old English such were very rarely used, and it is only in the 10th century that we begin to get such names as *Byrhsige Dyrincg*, i.e. Byrhsige son of Dyre, or, on the Scandinavian model, *Leafsi Dud-desum*. It must be clearly understood, however, that these second names, whether nicknames, as in *Eadric Streona*, i.e. Eadric the Grasper, or patronymics, were not as yet family or surnames. Each successive generation would have a new patronymic or a new nickname to suit the particular person in question. Such is the history of all patronymics in their early stage, whether the ones just indicated, or the Irish *O'*, the Scottish *Mac*, the Welsh *Ap*, or the French *Fitz*.

The Norman settlement affected English nomenclature yet more deeply. With it developed the common use of saints' names as Christian names, and these names, such as *John*, *Peter*, *Simon*, and other common Norman and French names, such as *Henry*, *Roger*, *Ralph*, rapidly ousted most of the English names in popularity. The range of names under the new rulers was not, however, nearly as wide a one as that found in Old English itself, and this has had an important consequence in developing the need for a second name, so as to distinguish from one another the large number of persons bearing the same name with whom one might be in daily contact. The Normans continued the Viking practice of using nicknames as second names, e.g. *Foljambe*, *Pettigrew*, i.e. *pieu de grue*. They brought in a new patronymic type, viz. *Fitz* (from *fil*), as in *Fitzjohn*, but most important was their influence in developing the practice whereby a man was distinguished from others of the same name by giving his place of birth or dwelling, e.g. *William de Feugers* (from Fougères in Brittany), *John de Aylesbury*. Such forms are very common from 1100 onwards, and are used of noble and peasant alike. The presence among one's ancestors

of some one with a name of this type is no certain criterion that he was of noble family, a lord of the manor, or anything of that kind.

At first such names were merely descriptive, as we have seen, of the man's place of birth or dwelling, but in course of time a man might move elsewhere and carry his name with him. This was specially common with clerics and civil servants. Thus John de *Kirkeby* may be parson of *Warton*, John de *Evesham* escheator of Wiltshire. The place of origin of these names is now often difficult to recognise, as they have sometimes survived in forms representing a local pronunciation which may now be lost, thus *Wyndham* is from *Wyndham*, *Esam* is from *Evesham*, *Wosnam* from *Wolstenholme*, or may have been thrown off at an earlier stage in the history of the name, thus *Kinwelmarsh* is from an earlier form of *Killa-marsh*.

A large number of other second names of local origin were formed, not from place-names, but from some landmark or physical feature of a larger place. Generally this is associated with the first name by the use of *atte(n)* (=at the), e.g. John *atten ashe* or *oke* (whence ultimately *Nash*, *Oak(s)*, *Nokes*), *atte townesende* (cf. *Townshend*), *atte stile* (cf. *Stiles*), *atte water* (becoming *Attwater*), *atte strete* (cf. *Street*). Some such names are derived from the sign which was found in those days on many houses besides inns; hence such names as *atte Crowne*, *Sterre* (cf. *Star(r)*), *Fleece*. Occasionally we have other prepositions, as in *Sim bythewatre* (cf. *Bywater*), *Peter underwode*. These belong more or less definitely to persons of non-noble origin. The fact that they are not common until the latter half of the 13th century may be due to the paucity of documents of an earlier date in which such persons would be likely to appear. Of almost equal importance with these second names of local origin are those denoting a man's occupation, e.g. Robert *le Parker*, John *le Hayward*, Philip *le Forester* (cf. *Foster*), *le Milnere* (cf. *Milner*, *Miller*), *le Mawere* (north country form of *mower*). Many represent forgotten trades, or are so disguised as to be unrecognisable, e.g. *Bo(w)yer*, *Fletcher* (=arrow-maker), *Bullinger* (Fr. *boulangier*, cf. *Baker*, *Baxter*). The use of nicknames developed to an extraordinary extent in the late 13th century, and continued for about a hundred years, though it may be that lack of satisfactory evidence (*v. supra*) is chiefly responsible for the apparent suddenness of the outburst. Examples are *Fallinthewell*, *Makepeace*, *Ca(t)chmaid*, *Stroklady*, *Loveday*, *Armstrong*, *Cruickshank*, *Lawless*, *Greensleeve*, *Ba(i)rnfather*. They cover a wide range of physical and mental peculiarities, habits, moral and immoral, tricks of speech, dress, &c. Many of them are incredibly primitive in their suggestion, and only a small proportion have survived as present-day surnames.

Certain types of second names readily became family or surnames. At least the eldest son in each successive generation of a feudal family would bear the same second name, derived from his estate, and so the second name would soon in effect become a family name. Good examples of this type are to be seen in such families as the Hampdens of Hampden, the Riddleys of Ridley. In a less degree the names of the *Oak*, *Ash*, *Stock*, *Bywater*-type would tend to become hereditary, in fact if not in law, so far as descendants of the first man so distinguished continued to live by the same landmark. Trades and professions tended to be hereditary, and names derived from them would be borne by successive generations. Nicknames would be very slow in becoming family names, and patronymics do not lend themselves readily to this process. It would seem to be in the latter half of

the 14th century that these second names began rapidly to develop into proper surnames, i.e. names borne by successive generations of a family regardless of the actual place of birth, abode, occupation, physical or mental qualities or parentage of the particular individual. Outward signs of the change are the dropping of the *de* or *atte* from names of local origin, and of the *le* from those of occupational origin, and the appearance of such names as Anne Simpson. A good illustration of the transition from one type to the other is found in two documents of 1332, in which *Thos. de Raan* and *John de Raan* are called alternatively *Thos.* (and *John*) son of *Walter Raans*. It is clear that they might also be called *Thos.* and *John Raans*, and that *Raan(s)* had now become a true surname. Incidentally it may be noted that this name illustrates another common feature of the new surnames, viz. that an *s* was often added to the name when it thus became hereditary. *Groves* replaces *atte Grove*, *Sims* and *Johns* are now as common as were *Simpson* and *Johnson*. While the use of the surname had become general by the end of the 14th century, it was by no means universal, and traces of older methods of nomenclature, though they may not be legally recognised, still linger in remote districts. One may notice specially the use in some parts of Yorkshire and Lancashire of such names as *John o' Mary's*, *Dick o' Bob's*, or even *John o' Tom o' Mary's*. The habit of calling a farmer by the name of his farm rather than by his actual surname is a common practice in Scotland to this day.

Lastly, in tracing out the history of a family-name in Modern English, it is well to bear in mind two points. First, a name as now used may go back to more than one quite different name in earlier days. *Simpson* may be *Sim's* son or come from *Simpson* (Bucks); *Wood(s)* may have had an ancestor who was *wode*, i.e. 'mad,' or have lived by a 'wood'; a *Chaucer* may be a *chauser*, 'maker of leather hose,' or a *chauffe-cire*, i.e. 'heat-wax,' a nickname given to a chancery clerk; *Woodhouse* may come from one of the numerous Midland *Wood-houses*, or it may be from *wodehouse*, i.e. 'wild man of the woods.' Secondly, names which are now carefully differentiated by the spelling may really be identical. *Smiths*, *Smyths*, *Smythes*, *Smijths* may well be all of the same family, though they insist on spelling their names differently. In M.E. all alike would be good spellings of the same name, and the spelling has no bearing on the age of the family. Similarly, the forms *Ffiennes* and *Ffoulkes* are due to ignorant misunderstanding of the names *Fiennes* and *Foulkes*, as written by mediaeval scribes with *ff* for *F*, a common orthographic device.

BIBLIOGRAPHY.—The chief Anglo-Saxon names will be found in Searle, *Onomasticon Saxonicum*, an invaluable collection, which needs, however, to be used with caution. Special studies of particular types of name are to be found in Redin, *Uncompounded Names in O.E.*; Forssner, *Continental Germanic Personal Names in England*; Björkman, *Nordische Personennamen in England und Zur Altenglischen Namenkunde*, all of them excellent contributions to the subject. Max Förster, *Keltisches Wortgut im Englischen* contains a full study of Celtic names in O.E. For M.E. and Modern English surnames the best books are Bardsley, *Dictionary of English and Welsh Surnames*; Harrison, *Surnames of the United Kingdom*; Weekley, *The Romance of Names and Surnames*. Weekley is the best, but by no means the fullest writer on this subject. All alike suffer from the fact that the mass of material is too vast for any single man to compass it, and this is specially true of the names which are derived from place-names, for we are only at the beginning of the work which can alone lead to their satisfactory interpretation (*v. infra*). A good summary of the most recent views upon Old and Middle English personal names, and the problems arising from them, will be found in a chapter by Stenton on 'Personal Names in

Place-names' in the *Introduction to the Survey of English Place-names*. For the study of Celtic names we may note Hogan, *Onomasticon Goidelicum*; for Frisian names, many of which are closely allied to English, Winkler, *Friesche naamlijst*; for German, Förstemann, *Alteutsches Namenbuch*; Heintze, *Die Deutschen Familien-namen*; Socin, *Mittelhochdeutsches Namenbuch*; for Manx, Moore, *Manx Surnames*. Lind, *Norsk-Islandska dopnamn* and *Norsk-Islandska Person-binamn* throw much light on Norse and Icelandic names; and Lundgren-Brate, *Personnamnen från medeltiden* on Swedish ones.

Place-names.—Place-names, like personal names, consist as a rule of two elements, one of which we may call the main element and the other the defining one, and the usual English order is to put the main element last, e.g. *New-ton*, *Roddles-worth*. The reverse order is common in Celtic, as in Welsh *Llanddewi*, 'church of Dewi or David,' Scottish *Dunkeld*, 'hill of the Caledonians,' Irish *Ath-cliaith*, 'ford of the hurdles,' the old name for Dublin, and Ekwall has shown us that traces of this method may be found in north-west England in names such as *Aspatria*, 'ash-Patrick,' *Setmarthy*, 'sætr (i.e. shealing) Murdoch,' which are due to Norse settlers familiar with Gaelic methods of place-nomenclature.

The main element may be descriptive of the situation, or it may have relation to the manner of the settlement. Apart from certain easily recognised words, such as *ford*, *hill*, the commonest elements of the former type, in their Modern English dress, are as follows: *beare*, 'swine-pasture,' *-borough*, *-berg(h)*, *-barrow*, from O.E. *beorg* or O.N. *berg*, 'hill,' *-den*, 'valley,' from O.E. *denu* or, chiefly in Kent and Sussex, 'swine-pasture,' from O.E. *denn*, *-don*, 'hill,' *-ey*, 'island,' *-hale*, 'nook, corner,' *-ham* (from O.E. *hamm*), 'enclosure,' often by water, *-law* *-low*, 'rounded hill, natural or artificial,' *-ho(e)*, 'spur of projecting land,' *-holm*, 'island' (Scand. in origin), *-hope*, 'small enclosed valley,' *-hurst*, 'wood or hill,' *-moor*, 'swamp,' *-shaw*, 'thicket,' *-ste(a)d*, 'place, site,' *-stoke*, *id.*, *-stow*, *id.*, but generally with a religious association, *-well*, *-wall*, 'spring.' Of the latter we may note *-bold*, *-bottle*, 'building,' *-bury*, *-borough*, *-burgh*, 'fort, fortified manor-house, borough, &c.,' *-chester*, *-caster*, *-cester*, 'fortified place of Roman or pre-Roman origin,' *-field*, 'open space, not enclosed area, as nowadays,' *-ham* (from O.E. *hām*), 'homestead, settlement, manor,' *-ley*, *-lee*, 'clearing,' *-ton*, *lit.* enclosure, then 'farm, manor, never 'town,' *-wick*, *-wich*, 'dwelling,' *-worth*, *-worthy*, *-wardine* (the last two being derivatives of the first) denoting primarily an enclosure. These are of English origin, but important also are *-by*, 'farm, village,' *-er*, *-erg*, *-arg(h)*, 'shealing,' *-scale*, *id.*, *-thwaite*, 'clearing,' all of Scandinavian origin, and *thorp(e)*, which can be either English or Scandinavian. When English it is usually found in disguised form as *-drop*, *-throp*, *-trap*, &c.

The defining elements may be best grouped according as they are (a) descriptive, (b) denote the owner or inhabitant(s) of the place. Of the descriptive type we may note (1) river or (rarely) hill-names, e.g. *Doncaster* on the *Don*, *Itchington* on the *Itchen*, *Whorlton* (Yorks) at the foot of the *Whorl*, or, less easily recognised, *Davenham* and *Davenport* on the *Dane*, *Dilston* on the *Devil's Water*, *Panfield* on a river once called the *Panta*, but now known as the *Blackwater*; (2) descriptive adjectives, e.g. *high*, as in *Higham*, *Healey*, *Heanton*, *Hanley*, *Henley*; *new*, as in *Newton*, *Newnham*, *Newington*, *Navinton*; the points of the compass, as in *Aston*, *Sutton*, *Sudbury*, *Nor(th)am*; reference to (3) the soil, e.g. *great*, *ceosel*, 'gravel,' as in *Girton*, *Chiselhampton*; (4) crops, e.g. *wheat*, in *Wheatley*, *Whatton*; *wood* in *Wadley*, *Woodhill*; (5) trees, plants, e.g. *Birkenside*, *Thornhill*, *Bromley*,

Hebden Bridge (O.E. *heope*, 'dog-rose'), *Farnham* (O.E. *fearn*, 'fern'); (6) animals and birds, e.g. *fox* in *Foxton*, *Foscott*, *goat* in *Gatton*, or in *Oxford*, *goose* in *Gosford*; but as most animal-names have at one time or another in their history been used also as personal names (*v. supra*), it is often not possible to be sure whether these names really belong here at all.

The descriptive defining element is the type most commonly found among the Celtic peoples, but among the Teutonic peoples it is less common than the use of the name of the owner, tenant, or inhabitant. This last was at first normally put in the genitive case, but all traces of the genitive inflexion may now be lost. The personal names are usually of English or Scandinavian origin, very rarely of French origin, as in *Bassettisbury*, while the only Celtic ones commonly found are those which had been adopted by Viking settlers, e.g. *Kiartan* in *Cartington*, *Maclmor* in *Melmerby*. Sometimes, as in *Bretton*, 'farm of the Britons,' we have reference to one or other of the various peoples that have gone to the making of our nation, but in such names as *Normanton*, *Irby*, it is as a rule impossible to say whether we have reference to a group of Norsemen or Irishmen (i.e. Norse settlers from Ireland) or to an individual person nicknamed 'Norseman' or 'Irishman.' In *Charlton*, *Walton*, and a few others of the same type, we have reference to some particular social class—in these cases to groups of *ceorls* or freemen, and *Welsh* (i.e. British) serfs.

Names of one element alone consist, as a rule, of one of the words commonly used as a main element, accompanied by no defining one, e.g. *Ford*, *Bridge*, *Minster*, *Hale*, *Bury*. These names, like others, were in actual speech usage often preceded by the preposition *at*, followed by the definite article, which was specially necessary, as there was no other defining word. *At then* (masc.) and *at ther* (fem.) became *atten*, *att(her)*, but later these forms were often misunderstood, and *atten Ash* was taken to be *atte Nash*, and a new place-name *Nash* evolved; *atter Ee*, 'at the river,' was taken to be *atte Re*, and the common river-name *Rea*, *Ree*, was thus coined; while, by a still more curious misunderstanding, *atther Lye*, 'at the clearing,' was taken to be *at Therlye*, and so arose the name *Thurleigh*, still pronounced *Thurly*. A type of somewhat similar origin is that found in *Byfleet*, lit. 'near the estuary,' *Bythorn*, 'near the thorn-bush,' and *Benwell*, earlier *binnanwealle*, i.e. 'within wall.' Comparatively rare are those names in which the defining element is used alone, either owing to actual loss of the main element or to the ease with which it may be mentally supplied, e.g. *Beccles*, i.e. *Beccel's* farm, *Bigods*, i.e. *Bigod's* manor.

Names which end in *-ing* and in *-ingham*, *-ington*, *-ingley*, &c., are very common, and call for a word of explanation. So far as these names are genuine, and not corruptions of other types (e.g. *Swarling* should really end in *-lynch*, *Bledington* should be *Bladinton*, for it is on the river *Bladen*, the old name for the *Evenlode*), they all contain an element *-ing*, commonly described as a patronymic suffix, but really of much wider application. In its plural form *-ingas* it could be added to a river-name, as in *Afeningas*, now *Avening*, to denote the people living on its banks, or to a personal name, as in *Mæccingas*, now *Matching*, to denote the people who had to do with *Mæcca*, his family, his servants, &c. In *-ingham*, earlier *-ingaham*, we have the gen. pl. of an *-ingas* name, and *Eglingham* denotes the 'homestead of Egwulf and his people.' In *-ington*, &c., we may have the gen. pl., as in *-ingham*, or we may have only *-ing* added to some personal name, e.g. a place once called *Wighelm-*

estun, i.e. *Wighelm's* farm, may come to be called *Wighelmington*, i.e. *Wighelm-farm*, in which we no longer have the idea of actual possession or tenancy on *Wighelm's* part, but only a vague suggestion of association of *Wighelm* with the farm at some stage in its history.

Many place-names and types of such can only be understood if we remember that in actual speech-usage they are very often preceded by a preposition, and that in early days that preposition would be followed by an inflected dative (or locative) form. Hence we may have pairs of forms, one derived from the nominative and the other from the dative, e.g. *-bergh* and *-barrow*, *-borough*; *-burgh* and *-bury*; *-haugh* and *-hale*; *-heugh* and *-ho(e)*; *-mead* and *-meadow*; *-leaze* and *-leasowe*. So also a good many elements may tend to be used in the plural, e.g. *barn* in *Barnes*, *byre* in *Byers Green*, and if these come to be used in the dat., at an early stage in their history they take the dat. pl. suffix in *-um*, which may appear later in various forms, e.g. *Eryholme*, *Arkholme*, dat. pl. of *ergh*, 'shealing,' *Ayresome*, *Newsham*, *Newsholme*, containing the dat. pl. of *hus*, 'house,' *Fenham*, dat. pl. of *fenn*, *Acomb*, dat. pl. of *ac*, 'oak.'

The names so far dealt with have been those of inhabited places. The names of natural features—rivers, hills, &c.—are of similar formation, though usually of Celtic origin rather than English, and may consist of one element or two, e.g. *Thames*, *Ouse*, *Swale*, on the one hand, *Greta* (Norse, 'gravel river'), *Divelish* (Celtic, 'deep stream'), on the other. These river-names are often used to name places on their banks. When the simple river-name is used, e.g. *Colne*, *Frome*, a practice that is specially common in the West and South-west, different places on the same stream have to be distinguished in various ways, e.g. by adjectives, as in *Upavon* and *Netheravon*, *Northill* and *Southill* (in which *-ill* represents the river *Ivel*), or, more commonly, by the name of the feudal tenant, as in *Earls Colne*, *Wakes Colne*, or by adding, presumably at a comparatively late date, some other name for the small settlement, as in *Winterbourne Zelston*, *Frome Vauchurch*. We have already seen how a river-name can be used as the defining element in a place-name. The existence of such comparatively easily recognised compounds, as have already been noted, or as *Ribchester* on the *Ribble*, *Bliford* on the *Blithe*, has often led to a wrong analysis of other names whose origin is obscure or difficult, and for which a ready solution may be found by this process. The rivers on which stand places such as *Chesham*, *Arundel*, *Cambridge*, have been given new names, *Chess*, *Arun*, *Cam*, technically known as back-formations, to fit the imagined etymology of the place-names in question. As a matter of fact *Chesham* is in early days *Cestresham*, 'homestead of or by the chester,' *Cambridge* is originally *Grantabrycg*, 'bridge over the Granta (the original name of the Cam),' while *Arundel* is probably 'hoarhound dell,' the name of the river flowing through it being really *Tarente*. These 'back-formations' are a source of much difficulty in place-name etymology. River-names are comparatively rarely mentioned in early documents, and in the absence of early evidence it is almost impossible to tell whether a place-name is derived from the name of the river on which the place itself stands, or whether the river-name is a comparatively modern formation from the place-name.

Of other types of place-name we need only note those in which two or more places of the same name are distinguished: (1) by some particular epithet, generally prefixed, or (2) by the addition of the name of their feudal owners. Under (1) we have the common use of *High*, *Low*, *Great*, *Little*, *Magna*, *Parva*, *Much*, or such names as *Steeple*

Bumpstead, Stratton Strawless, Kirby Muxloe (lit. muckless), *Fenny Drayton*, or names like *Poulton-le-Fylde, Chester-le-Street*, in which Norman scribes have shown their relationship to some distinguishing object by the use of the article *le*. Under (2) we may note *Helion Bumpstead*, from a Breton lord named *Helion, Monks Risborough, Ashby de la Zouche, Theydon Garnon, Ashby Puerorum* (the income of the manor being used for the endowment of the boys of Lincoln Cathedral).

In any study of place-names it is of cardinal importance to realise that it is impossible to come to any satisfactory conclusion as to their meaning and interpretation if we are dependent on the modern form alone. Place-names have, like ordinary words, only to a greater degree, changed in the process of transmission from one generation to another. In ordinary words these processes are to a large extent checked by the existence of the written or printed word, but place-names, especially those of the smaller places, are not often thus brought before one's eyes, and can undergo rapid and unnoticed changes. They soon lose any significance that they may have in themselves, and change of form is not checked by the desire to secure continuity of significance. Some of the causes, processes, and results of these changes may be illustrated. (1) Place-names belonging originally to one language have been taken over by people using a different language, and, in adapting them to their own methods of speaking or writing, they have often completely transformed them. *Esk, Eve, Aze, Usl, Wiske*, are the variant forms in which the same Celtic word for water appears in river-names in different parts of England. Norman lords found a difficulty in pronouncing English names, and Norman scribes a difficulty in transcribing them. The modern forms of many names bear witness to this, as in *Durham* (N. Fr. *Dur-esme*) for earlier *Dunholm*, *Turnworth* for *Thornworth*, the *-cester* of *Worcester, Cirencester* in contrast to the usual *-chester*. English peasants had difficulty with Norman names, and N. Fr. *beau repair*, 'beautiful retreat,' appears as *Belper, Bear Park, Beurepaire*. Viking settlers transformed English names into allied Scandinavian forms; thus O.E. *Eoforwic* becomes *Jorvik*, later *York*. (2) Place-names consist as a rule of more than one syllable, and are specially affected by the laws of English accent, whereby the vowels of weak or unstressed syllables are weakened or lost, at least in pronunciation, though not always in spelling: thus *Cantwarabyrig* becomes *Canterbury*, and *Knowsley* is from *Cenulfesleah*. This is of special importance as affecting the form of the second or main element in a place-name. It falls in a weak-stressed position, and as a result confusion may arise; thus unstressed *beorg*, 'hill,' and *burh*, 'fort,' *dun*, 'hill,' and *denu*, 'valley,' *-hale*, 'nook,' *-hill* and *-hall*, *-lund* (Norse, 'grove') and *-land* are so alike in pronunciation that a great many *hale*-names are written as if they ended in *-hall* or *-hill*, *don*-names as *den*-names. Most of the *-borough* names in Southern England are not *burhs* at all, but *beorgs*, &c. Further misunderstandings may arise owing to common sound developments, e.g. *-don*, after a defining element such as *Hart* or *Heath*, may appear as *-ton*, as in *Hayton* and *Hetton*. Places in the gen. sing. of a personal name + *-ey* (=island) once ended in *-sey*; association with water has now led to their often being spelt with *-sea*, and no one would suspect the true origin of *Mersea*. Similarly, names in *-stan*, later *-ston*, may be misunderstood, and taken to be from a personal name in the gen. + *-ton*, or names in a gen. + *-ton* may come to be written with *-stone*, e.g. *Knighstone* (Dev.) is a *-ton* name. (3) Dialectal differences may obscure true identity of origin.

Caistor is a dialect variant of *Chester*; *Rodge, Rudge* (and at times *Reach*) of *Ridge*; *Hull* (occasionally) of *Hill*. These relations may at times be further obscured by the replacing of the true dialect form by the Standard English one. *Hythe* in Kent should be *Hethe*, but the Midland and S. Eng. form *hithe* (= 'landing-place') has ousted the local one. (4) The modern map is full of perverted forms. Some are due to folk-etymology—i.e. the attempt to give some significance to a name by suggesting its etymology—e.g. *Devils Brook* for *Divelish Brook*, in which we really have a Celtic river-name (*v. supra*), others to attempts at the picturesque, e.g. *Eaglescliffe* for *Egglescliffe*, others to sheer blunders, e.g. *Hankham* in the Pevensy Levels, is now written *Hancombe*, when there is not a vestige of a *combe*, and the suffix *-ham* can be traced right back to the 10th century.

The value of place-names for the reconstruction of the past history of a country, especially where it has been subject to successive waves of invasion by peoples of different nationality, has long been recognised, and in recent years we have had from Ekwall and other scholars examples of the scientific application of this study to such questions as the survival of the Celtic population in Britain at the time of the English Conquest, the extent and character of the Scandinavian settlements in England.

The problem of pronouncing English place-names correctly is notoriously a difficult one, for again and again the spelling is no guide to the local pronunciation—e.g. *Daventry* for *Daintry, Beaconsfield* for *Beckonsfield, Tideswell* for *Tidza, Chagford* for *Chaggyford*. Again and again the written record has failed to keep pace with the actual development of the pronunciation, or has (as we have just seen) been deliberately changed for ulterior purposes. Unfortunately, with the growth of the power of the written word, consequent upon printing and education, these spelling pronunciations are gradually ousting the local ones, which are at the same time the only truly correct ones.

BIBLIOGRAPHY.—Johnston, *Place-names of England and Wales*, deals with a good number of names in the countries named, but the time is hardly ripe for a book of so wide and general a character. Monographs upon the place-names of various English counties have appeared as follows: Alexander (*Oxfordshire*), Baddeley (*Gloucestershire*), Bowcock (*Shropshire*), Bannister (*Herefordshire*), Duignan (*Staffordshire, Warwickshire, Worcestershire*), Ekblom (*Wiltshire*), Ekwall (*Lancashire*), Goodall (*South-west Yorkshire*), Gover (*Middlesex*), Mawer (*Northumberland and Durham*), Moorman (*West Riding*), Mutschmann (*Nottinghamshire*), Skeat (*Bedfordshire, Cambridgeshire, Berkshire, Hertfordshire, Suffolk*), Stenton (*Berkshire*), Walker (*Derbyshire*), Wyld (*Lancashire*). Of these, the only one that is entirely satisfactory and adequate is Ekwall's *Lancashire*. Ekwall's *Scandinavians and Celts in N.W. England* and his *English Place-names in -ing*, and Lindkvist's *Middle English Place-names of Scandinavian Origin*, are excellent studies of particular problems. With the approval and encouragement of the British Academy a Survey of English Place-names has now been undertaken, and the results of that work are being published under the auspices of the English Place-name Society. The first volume, in the form of an *Introduction to the Survey of English Place-names*, was recently published. Johnston has written a book on the *Place-names of Scotland* as a whole, and volumes upon those of various counties have also appeared, but they are of widely varying quality. Some material for Wales will be found in Morgan's *Place-names of Wales*. For France, the best book is Longnon, *Les Noms de Lieu de la France*; for Germany, Förstemann, *Altdeutsches Namenbuch*. Norway has completed a survey of its place-names—*Norske Gaardnavne*, ed. Rygh and others; Sweden is in process of publishing such a survey under the auspices of a national committee (Kungl. Örtannskomitee), and work upon the provinces of Alvsborg and Värmland has

already appeared; Denmark has commenced one, and the first volume upon the place-names of the island of Samsø (*Danmarks Stednavne*, No. 1) appeared in 1922. For the Netherlands we have *Nomina Geographica Neerlandica*. Joyce has issued three volumes on the *Place-names of Ireland*, and there is one by Moore on those of the Isle of Man.

Namur (Flem. *Namen*), a city of Belgium, at the confluence of the Sambre with the Meuse, 35 miles by rail SE. of Brussels. The greater part of the picturesque citadel (1784) is transformed into a pleasure-ground; and the other old fortifications have been razed since 1866. The town itself has suffered so much by war that it offers little of interest—the cathedral, completed in 1772, with the grave of Don John of Austria; the Jesuit church of St Loup (1653), a large military school, an antiquarian museum, monuments of Leopold I. and the geologist Omalius d'Hallo (1783–1875), &c. Namur is noted for its cutlery, and also manufactures firearms, leather, paper, and tobacco. Pop. 30,000. Namur was captured by Louis XIV. in 1692, but recaptured in 1695, after a ten weeks' siege, by William III. and 'my uncle Toby'; and taken in 1914 by the Germans.

The province of Namur, on the French frontier, lying between Hainault and Luxembourg, has an area of 1414 sq. m. Fertile and rich in minerals, it is watered by the Meuse, Sambre, and Lesse, and traversed by wooded spurs of the Ardennes (2000 feet). Pop. 350,000.

Nanaimo, a town on the east coast of Vancouver Island, 74 miles by rail NNW. of Victoria. There are large coal-mines in the district, and the town is the chief seat of this trade. Pop. 9000.

Nana Sahib, the name under which Dundhu Panth, adopted son of the ex-peshwa of the Mahrattas, became known as the leader of the Indian Mutiny in 1857. Born about 1821, the son of a Brahmin in the Deccan, and educated as a Hindu nobleman, he was bitterly disappointed that when the peshwa died in 1851 the latter's pension was not continued to himself; and, industrious in fanning discontent with the English rule, on the outbreak of the Mutiny he was proclaimed peshwa. After the suppression of the rebellion he escaped into Nepal. The date of his death is not known.

Nancy, a beautiful French town, capital of the department of Meurthe-et-Moselle, lies on the left bank of the river Meurthe, at the foot of wooded and vine-clad hills, 220 miles by rail E. of Paris and 94 W. of Strasburg. It comprises, besides several suburbs, the old and new towns (the former with narrow irregular streets, the latter open and handsome). It contains many fine squares and imposing edifices, and owes much of its architectural adornment to Stanislas Leszczynski, who, after abdicating the crown of Poland in 1735, continued to reside here as Duke of Lorraine till his death in 1766. His statue (1831) stands in the Place Stanislas, the principal square, which is surrounded by important public buildings, as the hôtel-de-ville, the bishop's palace, and the theatre. Other noteworthy features are the cathedral (1742); the churches Des Cordeliers and Notre Dame de Bon Secours (1738), both with interesting monuments; St Epvre (1875); the 16th-century ducal palace, with the Lorraine museum; statues of General Drouot (1853) and Thiers (1879); and half-a-dozen gates, looking more like triumphal arches. The institutions include a university, whose library was destroyed by bombardment just before the armistice of 1918. It has been the main centre of research into the therapeutic value of hypnotism. Nancy, which grew much in importance after the German annexation of Alsace-Lorraine, has manufactures of cotton and woollen goods, artificial flowers, iron, tobacco, &c.; but its staple industry

is embroidery on cambric and muslin. Pop. (1872) 52,565; (1911) 119,949; (1921) 113,226. Nancy, dating from the 12th century, was the capital of the duchy of Lorraine (q.v.). It was the scene of the death of Charles the Bold (1477).

Nanda Devi. See HIMALAYA.

Nandu. See RHEA.

Nanking, officially KIANGNING, capital of Kiangsu, till the 15th century the capital of China, on the Yangtsze River, 130 miles from its mouth. From 1853 to 1864 it was the capital of the Taipings (q.v.), and it has never recovered from the desolation then caused; memorable buildings destroyed were the Porcelain Tower (see CHINA; also PAGODA), the summer palace, and the tombs of the kings. It suffered again in the revolutionary war. The walls were 30 miles around, in places 70 feet high. There is here an arsenal on the European model. In 1842 Nanking was captured by the British and a treaty signed. By the treaty of Tientsin (1858) it was nominally opened to foreign trade. It has a university and other colleges. Pop. 400,000.

Nansen, FRIDTIOF, Arctic voyager, was born, the son of an official, 10th October 1861, near Christiania (Oslo), and studied there, as well as later at Naples. In 1882 he made a voyage into the Arctic regions in the sealer *Viking*, and on his return was made keeper of the natural history department of the museum at Bergen. In the summer of 1888 he made an adventurous journey, accompanied by two Norwegians and three Lapps, across Greenland from east to west. He described the voyage in *The First Crossing of Greenland* (trans. 1890). But his great achievement was the partial accomplishment of his scheme for reaching the North Pole by letting himself and his ship get frozen into the ice north of Siberia and drift with a current setting towards Greenland. He actually started in the *Fram*, built for the purpose, in August 1893, reached the New Siberian islands in September, made fast to an ice-floe, and gradually drifted north to 84° 4' on 3d March 1895. There, accompanied by Johansen, he left the *Fram* and pushed across the ice, reaching the highest latitude till then attained, 86° 14' N., on 7th April. The two wintered in Franz Josef Land, and in June 1896 met the Jackson-Harmsworth expedition there. Nansen arrived in August in Norway, followed by the *Fram*, *viâ* Spitsbergen. In 1897 he became professor of Zoology, in 1908 of Oceanography, and in 1918 rector magnificus at Christiania, and in 1905–8 he was Norwegian ambassador in London. He did much work in connection with the League of Nations, repatriation of prisoners of war, relief of Russian and Anatolian refugees and of Russian famine-sufferers. See his *Farthest North* (1897) and *Scientific Results* (1900 *et seq.*); his *Life* (trans. 1896); *In Northern Mists* (an early Arctic exploration, 1911); *Through Siberia* (1914); *Hunting and Adventure in the Arctic* (1925).

Nantes, the sixth in size of the cities of France, capital of the department of Loire-Inférieure, lies on the right bank of the tidal Loire (here 2000 yards wide), 35 miles from the sea, and 248 by rail SW. of Paris. The natural beauties of the site have been much improved by art, and, the old town having been demolished between 1865 and 1870, Nantes is one of the handsomest cities in all France, with its noble river, quays, bridges, shady boulevards, squares, and statues. The unfinished cathedral (1434–1852) contains Colomb's splendid monument (1507) to the last Duke and Duchess of Brittany, and another (1879) to General Lamoricière. The ducal castle, founded in 938, and rebuilt in 1466, was the occasional residence of Charles VIII. and most of his successors, the

prison of Cardinal de Retz and Fouquet, and the place where on 15th April 1598 Henry IV. signed the famous Edict of Nantes, which gave freedom of religion to the Huguenots (q.v.), and whose revocation by Louis XIV. on 18th October 1685 drove 400,000 French into exile. Other noteworthy buildings are the splendid church of St Nicholas (1854), the palais de justice (1853), the theatre (1787), and the post-office, besides a museum, a picture-gallery, and a library. In the 19th and 20th centuries great sums have been expended on harbour-works, but the rise since 1845 of the port of St Nazaire (q.v.), near the mouth of the Loire, and increasing difficulty in the navigation of the river, combined with depression of trade to reduce the commercial importance of Nantes; to restore which was the object of the ship-canal (1891) between the two places. The chief exports are cereals, iron ores, building material, sugar, and preserved provisions, the chief imports sugar, iron, coal, phosphate, timber, wood-pulp, nitrate of soda, and wines. Shipbuilding has greatly fallen off, but is still one of the leading industries, together with the preparation of sardines, and the manufacture of thread, sugar, leather, iron, nets, soap, machinery, &c.; whilst 10 miles below Nantes is the vast government steam-engine factory of Indret, familiar to every reader of Daudet's *Jack*. Pop. of Nantes (1872) 112,947; (1921) 183,704. The *Portus Namnetum* of the Romans, and the former capital of Brittany—a rank it disputed with Rennes—Nantes has witnessed the marriage of Anne of Brittany to Louis XII. (1499), the embarkation of the Young Pretender (1745), the 'noyades' of the execrable Carrier (q.v.), the fall of the Vendéan leader Cathelineau (1793), and the arrest of the Duchess of Berri (1832). Fouché was a native.

Nantucket, an island (15 miles long) off the south-east coast of Massachusetts. On the north shore is Nantucket town (pop. 3000), with a nearly landlocked harbour. It was formerly a great seat of the whale-fishery, but is now mainly noted as a summer-resort.

Nantwich, a market-town of Cheshire, on the Weaver, 4 miles SW. of Crewe. It has some quaint old timber houses; a fine cruciform parish church, Early English to Perpendicular in style, with a central octagonal tower, 110 feet high; a Gothic town-hall (1858); a market-hall (1867); a grammar-school (1611); and brine-baths (1883). The *Halen Gwyn* ('white salt town') of the Welsh, Nantwich was once the second largest town in Cheshire, the seat of 300 salt-works in Leland's day, a number reduced to 100 through the discovery of better brine-pits in other parts of the Weaver's valley in 1624, since which date the industry has gradually quite died out. Ready-made clothing and tanning are now the principal industries. A great fire (1583), and its siege by the royalists under Lord Byron (1644), are the chief events in its history. Pop. (1851) 5424; (1881) 7495; (1921) 7296.

Napata. See ETHIOPIA.

Naphtha is derived from the Persian word *nafata*, 'to exude,' and was originally applied to liquid hydrocarbons which exude from the ground in the neighbourhood of the Caspian Sea; in like manner it was applied to the natural oils found more or less plentifully in nearly all countries of the world, and also to the oil distilled from Bog-head mineral in Scotland. But the inconvenience and danger of classing all these oils indiscriminately as naphthas became apparent after the Scottish paraffin and the American petroleum refined oils began to be used for domestic illumination. The word naphtha is still used in a very general and vague sense, and has no specific application

either scientifically or commercially to any particular liquid; but since the more general application of the words paraffin and petroleum to mineral oils the sense in which the word naphtha is used has been narrowed considerably. The various British Petroleum Acts since 1862 have also aided in the interest of public safety in emphasising the wise distinction now made between the heavier and safe hydrocarbon oils on the one hand, and the volatile and unsafe hydrocarbon spirits or naphthas on the other.

Commercially, naphtha is now understood to apply to the inflammable distillates of crude mineral oils and coal-tar. For trade convenience the volatile distillates of petroleum and shale oil are known respectively as petroleum spirit and shale spirit, to distinguish each from the other, and both from coal-tar naphtha. The term naphtha also embraces distillates of india-rubber, bones, peat, and wood, the last of these being known as wood-spirit or methyl alcohol. A few words with regard to each of these naphthas may serve to indicate more particularly the nature and method of production, and also the uses to which they are applied.

Petroleum spirit is obtained from crude petroleum in the process of refinement by distillation. The first or lightest portion of the oil which passes over from the still, being highly inflammable, is not allowed to mix with the burning oil, but is run into a separate or naphtha tank. American crude petroleum yields from 15 to 20 per cent. of crude naphtha, which in some of the refineries is separated into gasoline, sp. gr. '640 to '650; benzine, sp. gr. '670 to '710; and benzoline or deodorised spirit, sp. gr. '710 to '730. Russian crude petroleum yields a comparatively small proportion of naphtha, about 5 or 6 per cent., which is separated into light benzine and heavy benzine, varying in sp. gr. from '730 to '775. Shale spirit is a product of the crude oil distilled from shale, which is one of the important mining and chemical industries of Scotland. This crude oil contains 4 to 5 per cent. of naphtha, having a sp. gr. of '715 to '740; but some of the shale-oil works produce a small quantity of gasoline with a sp. gr. of '640 to '680. Coal-tar naphtha is distilled from the tar obtained from coal in gas-works. The production of tar is 10 to 12 gallons per ton of coal put through the retorts. This tar on distillation yields from 5 to 20 per cent. of naphtha according to the quality of coal used. Gas-tar from Newcastle coal gives only 5 per cent. of naphtha, while the tar from some cannel coals yields as much as 20 per cent. Coal-tar naphtha has a sp. gr. varying from '850 to '950, and is thus much heavier than the naphthas obtained from crude mineral oils. Coal-tar naphtha may be fractionated into a variety of hydrocarbons with boiling-points ranging from 175° to 350°; but the two of the greatest commercial importance are benzole and ordinary naphtha. Caoutchine is a naphtha obtained by the destructive distillation of caoutchouc or india-rubber. It also may be fractionated into a number of hydrocarbons of different densities and boiling-points. Bone-naphtha is obtained by the distillation of bones in the manufacture of animal charcoal. It is known also as bone-oil, or Dippel's animal oil. Owing to some neutral or nitrogenous substance as yet unknown, it possesses a peculiarly offensive smell, and until some easy means is discovered of removing this very objectionable feature bone-oil can never become of much use as a naphtha. The crude naphthas obtained from these various sources are all refined or purified by similar processes—viz. simple redistillation by means of steam, as in America, for the lightest fractions; but for the heavier spirits a treatment with sulphuric acid

and then with caustic soda, and a subsequent washing with water are necessary previous to redistillation.

The uses to which in the industrial arts the different qualities of naphtha are applied are very numerous. The lighter spirits, such as benzole and benzine, being solvents of grease and oil, are used for detergent purposes. Benzoline was for some years burned pretty generally by the poorer classes in cheap benzoline or sponge lamps; but its use in this way has happily been greatly restricted, if not quite superseded, by the low price at which petroleum and paraffin oils have for some years been obtainable. The light naphthas are also used for extracting the perfumes of flowers and plants, and the oil from various seeds. The bulk of the coal-tar naphtha, and much of the shale and petroleum spirit, are employed as solvents in the manufacture of india-rubber and gutta-percha goods. They are also solvents of wax, and fatty and resinous bodies generally, and are so used in refining the best qualities of paraffin wax. Large quantities are consumed in naphtha, torch, and other flaring lamps for outside use. They are also used as a substitute for turpentine in the preparation of paints; and in Scotland the solvent action of shale spirit is turned to account in the preparation of an anti-damp or stone- and timber-preserving fluid called Alexinoton. A considerable percentage of paraffin wax is dissolved and held in solution by the spirit; and if this liquid be applied to freestone, brick, or wood, it passes into the pores of the material, and the spirit rapidly evaporating leaves the wax permanently in the stone or wood, so that water cannot be absorbed by it.

Naphthalene, $C_{10}H_8$, is a solid substance obtained from Coal-tar (q.v.). It forms thin, transparent, brilliant plates with a pearly lustre and unctuous to the touch. It melts at $176^{\circ} F.$ ($80^{\circ} C.$) and boils at $422^{\circ} F.$ ($217^{\circ} C.$), but it readily sublimates at a much lower temperature. It has antiseptic properties. It is used in the manufacture of indigo and a number of azo dyes. Naphthalene is of most importance from a scientific standpoint. Its molecule of $C_{10}H_8$ may be regarded as made up of two aromatic nuclei, having two atoms of carbon in common; but for further information on this point, see AROMATIC SERIES. Naphthalene forms an extensive series of derivatives in which one or more atoms of hydrogen are replaced by NO_2 , chlorine, bromine, &c.

Napier, the chief port and city of the provincial district of Hawke's Bay, New Zealand, on the east coast of the North Island. Port Ahuriri (or Seinde Island), where most of the wholesale stores are situated, is within the municipal boundary. The harbour has been deepened in order to accommodate large vessels. There is a considerable export of wool, also tinned and frozen meat, and timber. Napier is the seat of the bishop of Waiapu. A fine cathedral was built in 1888. Pop. 17,000.

Napier, SIR CHARLES, English admiral, was cousin to the hero of Sind and the historian of the Peninsular war, and was born 6th March 1786 at Merchiston Hall, near Falkirk. At thirteen he went to sea as a naval volunteer. In 1808 he received the command of the *Recruit*, 18 guns, and had his thigh broken by a bullet. He kept up a running fight in the West Indies with a French line-of-battle ship, and assisted in her capture. This obtained him a post-captaincy; but being thrown out of active service, he served ashore as a volunteer in the Peninsular army, and was wounded at Busaco. Commanding the *Thames* in 1811, he inflicted an incredible amount of damage upon the enemy in the Mediterranean. In 1814 he led the way in the hazardous ascent and descent

of the Potomac; and he took an active part in the operations against Baltimore. In 1829 he received the command of the *Galatea*, a 42-gun frigate, and was employed 'on particular service' on the coast of Portugal. Becoming acquainted with the leaders of the Constitutional party, he accepted the command of the fleet of the young queen; and by defeating the Miguelite fleet he concluded the war, and placed Donna Maria on the throne. He was made admiral-in-chief of the Portuguese navy, and attempted to remodel it; but official and corrupt influence was too strong for him, and he returned to England. In the war between the Porte and Mehemet Ali he organised a land force, with which he stormed Sidon and defeated Ibrahim Pasha among the heights of Mount Lebanon. He took part in the naval attack on Acre, blockaded Alexandria, and concluded a convention with Mehemet Ali. In 1847, now a K.C.B., he received the command of the Channel fleet. When the Russian war broke out he was sent out to command the Baltic fleet; but the capture of Bomarsund failed to realise the high expectations formed, and he was deprived of his command. He twice sat in parliament, for Marylebone and Southwark, and, until his death at his Hampshire seat, Merchiston Hall, November 6, 1860, he laboured to reform the naval administration. See his *Life and Correspondence* (1862), and his *Life and Letters* by H. N. Williams (1917).

Napier, SIR CHARLES JAMES, the conqueror of Sind, was great-grandson of the fifth Lord Napier and a descendant of Napier of Merchiston. He was born at Westminster, 10th August 1782, and, having received a commission in his twelfth year, served in Ireland during the rebellion. He commanded the 50th Foot during the retreat on Coruña; and at the fatal battle in which Sir John Moore fell he was wounded in five places and made prisoner. Marshal Ney dismissed him, with permission to go to England, where he engaged in literary work, and even wrote an historical romance. In 1811 he returned to the Peninsula. At Coa, where he fought as a volunteer, he had two horses shot under him. At Busaco he was shot in the face, having his jaw broken and his eye injured. He recovered in time to be present at the battle of Fuentes d'Oñoro and the second siege of Badajoz. He took part in a fighting cruise off the Chesapeake, capturing American vessels, and making frequent descents upon the coasts. He did not return to Europe soon enough for Waterloo, but was engaged in the storming of Cambrai, and accompanied the army to Paris. After the peace he was, in 1818, made governor of the island of Cephalonia, the affairs of which he administered with great energy and intelligence; but, being of an excessively combative disposition, he became embroiled with the authorities at home. In 1838 he was made a K.C.B., and in 1841 was ordered to India to assume the command of the army of Bombay against the amirs of Sind. His destruction of a fortification called Emaun Ghur, in 1843, was a most remarkable military feat. The fearful battle of Meeanee (q.v.), on 17th February, followed, where Napier, with 8000 English and sepoy, defeated 22,000 Baluchis, strongly posted. The amirs surrendered, except Shere Mohammed, who brought 25,000 men into line of battle at Hyderabad. Napier had only 5000 men, but in three hours his little army gained a decisive victory. A few days afterwards Napier was in the palace of the amirs, and master of Sind; and after the annexation Lord Ellenborough made him governor of Sind. He gained the respect and reverence of the inhabitants, but soon became engaged in an acrimonious war of despatches with the British authorities. In 1847 he returned to England.

After attending a series of festivals in his honour, he lived in retirement until the disasters of the Sikh war caused the eyes of his countrymen to be turned to the hero of Sind. He went to India, but found on his arrival that the Sikhs had been routed. He now turned his attention, as commander-in-chief of the army in India, to the subject of military reform, and quarrelled with Lord Dalhousie. He bade a final adieu to the East in 1851, and returned to his native country, where he resided until his death, which took place at his seat, at Oaklands, near Portsmouth, on 29th August 1853. He had then attained the rank of lieutenant-general, was G.C.B., and colonel of the 22d Foot. It must be remembered to his honour that he was the first English general who ever recorded in his despatches the names of private soldiers who had distinguished themselves, side by side with those of officers. Brave to rashness, ready alike with tongue, pen, and sword, quarrelsome with his superiors, but beloved by his soldiers, and, to crown all, of wild yet noble and striking appearance, Napier was one of the most remarkable men of his time. See *Lives* by his brother (4 vols. 1857), W. Napier Bruce (1885), Sir W. Butler (1890), and T. Rice Holmes (1925).

His brother, SIR WILLIAM FRANCIS PATRICK NAPIER, K.C.B., was born 17th December 1785, served in the Peninsular campaign, and became lieutenant-general. Besides his famous *History of the War in the Peninsula* (6 vols. 1828-40), he published *The Conquest of Scinde* (1845), and the *Life of his brother Sir Charles* (1857). He died at Clapham, 12th February 1860. See his *Life* by H. A. Bruce (1864).

Napier, JOHN, Laird of Merchiston, was born at Merchiston Castle, near Edinburgh, in 1550. He matriculated at St Andrews in 1563, and travelled for some time on the Continent, returning to his native country highly informed and cultivated; but, declining all civil employments, he preferred the seclusion of a life devoted to literary and scientific study. In 1593, however, he was one of a deputation of six to the king regarding the punishment of the 'Popish Rebels,' and in the same year he published his *Plaine Discovery* (or 'Interpretation') of the whole Revelation of Saint John (revised ed. 1611; 5th ed. 4to, 1645). In the dedication to King James VI. he gave his majesty some very plain advice regarding the propriety of reforming his 'house, family, and court;' and the work went through numerous editions in English, Dutch, French, and German. In July 1594 he made a contract with Logan of Restalrig for the discovery of treasure in Fast Castle. About this time he seems to have devoted much of his time to the invention of warlike machines for the defence of the country against Philip of Spain, and a list of the same exists at Lambeth Palace, dated 1596. Like other eminent men of the time, Napier, though a strict Presbyterian, seems to have been a believer in astrology and divination. In 1596 he proposed the use of salt as a fertiliser of land. In 1614 he first gave to the world his famous invention of Logarithms (q.v.), in a treatise entitled *Mirifici Logarithmorum Canonis Descriptio* (trans. Wright, 1616). Napier's next work was *Rabdologie seu Numerationis per Virgulas libri duo* (1617), detailing an invention for simplifying and shortening the processes of multiplication and division mechanically by means of the device subsequently known as *Napier's Bones*—an arrangement of narrow slips of bone, ivory, metal, or pasteboard, inscribed with figures. This ingenious contrivance, however, was superseded by his logarithms. He also prepared a second work on logarithms, showing their mode of construction and application, with an appendix

containing several propositions of spherical trigonometry, and those formulæ which are now known by his name. This work was published after his death (4th April 1617) by his son Robert in 1619. There is an English translation by W. R. Macdonald, *The Construction of the Wonderful Canon of Logarithms*, with a catalogue of the various editions of Napier's works (1889). Napier's eldest son, Archibald, was raised to the peerage as the first Lord Napier by Charles I. in 1627.

See *Lives* by Lord Buchan (1787) and by Mark Napier (1834), who also edited *Ars Logistica*, 'The Baron of Merchiston his booke of Arithmeticke and Algebra' (1839), from a manuscript copy for the Bannatyne Club. This work had been transcribed from Napier's notes by his son Robert. See the *Napier Tercentenary Volume*, ed. C. G. Knott (1915), and Hume Brown, *Surveys of Scottish History* (1919).

Napier, MACVEY, born at Glasgow, 11th April 1776, was educated there and in Edinburgh, and in 1799 became a writer to the Signet, in 1805 Signet Librarian (which post he retained till 1837), and in 1824 first professor of Conveyancing. He edited the supplement to the fifth edition of the *Encyclopædia Britannica* (6 vols. 1816-24), and in 1829 succeeded Jeffrey as editor of the *Edinburgh Review* (q.v.). Among his contributors were Macaulay, Carlyle, J. S. Mill, Sir William Hamilton, and (alas for the editor!) Brougham. He died 11th February 1847. See his interesting *Correspondence* (1879).

Napier of Magdala, LORD. Robert Cornelius Napier was born in Ceylon, 6th December 1810, and was educated at the Military College at Addiscombe. He entered the Bengal Engineers in 1826, served in the Sutlej campaign, was wounded while acting as chief-engineer at the siege of Multan, and had a prominent share in the battle of Gujrat. As chief-engineer of the Punjab, with the rank of colonel, he greatly developed the resources of the country. During the Indian Mutiny he was chief-engineer in Sir Colin Campbell's army, and especially distinguished himself at the siege of Lucknow, and was made K.C.B. He received the thanks of parliament for his services in the Chinese war of 1858. As commander of the expedition in Abyssinia (q.v.) in 1868, he achieved a brilliant success, both by his whole management of the short campaign and in the storming of Magdala, which ended it. On his return he received the thanks of parliament, an annuity of £2000, was made G.C.B., and created Baron Napier of Magdala. In 1870 he was appointed Commander-in-chief of the forces in India, and nominated a member of the Indian Council. In 1876-82 he was governor of Gibraltar, and on resigning was made Field-marshal, in 1886 Constable of the Tower. He died 14th January 1890.

Naples owed its foundation to a body of Greek colonists, two settlements, Palæopolis and Neapolis, existing for many years side by side as one community, Parthenope. In 328 B.C. both were subdued by Rome; from that time Palæopolis disappears, whilst its neighbour was made an ally of Rome. It resisted Pyrrhus, deterred Hannibal, but fell through treachery into the hands of Sulla's partisans (82 B.C.), who massacred the people. Under the empire it was a favourite place of residence for the emperors and the upper classes of Rome, and of the poets Virgil, Statius, Silius Italicus, luxury and pleasure, and its beautiful climate, being the sources of attraction. After Rome fell, it sided with the Goths, but was seized by Belisarius (536), and six years later by Totila. Narses recovered it soon after for the Byzantine emperors, who made it the head of a duchy. This in the beginning of the 8th century asserted its independence, and retained it until the whole country was subdued by the Normans in the

11th century. To the Norman dynasty succeeded that of the Hohenstaufen. But their arch-enemies, the popes, conferred the sovereignty of Naples upon Charles of Anjou, who in the battle of Benevento (1266) annihilated the power of the imperial (Ghibelline) party. The predominance of the papal (Guelph) party during the reign of Robert I., who was the patron of Dante and Boccaccio, the depraved libertinism of his heiress and granddaughter Joanna, the ravages committed by German mercenaries and by the plague, futile attempts to recover Sicily, and the feuds of rival claimants to the throne, are the leading features during the rule of the Angevine dynasty, which expired with the profligate Joanna II. in 1435. It was succeeded by that of Aragon, which had ruled Sicily from the time of the Sicilian Vespers (1282). During the tenure of the Aragon line, various unsuccessful attempts were made by the House of Anjou to recover their lost sovereignty; and the country, especially near the seacoast, was repeatedly ravaged by the Turks. Between 1494 and 1504 the French and Spanish disputed between them the possession of Naples, and victory inclined to the latter. Naples was united with Sicily, forming the kingdom of the Two Sicilies, and was governed by viceroys of Spain down to 1707. The most striking episode during this period was the revolt of Masaniello (q.v.). During the war of the Spanish Succession (q.v.), Naples was wrested from Spain by Austria (1707); but in 1735 was given to Don Carlos, third son of Philip V. of Spain, who

founded the Bourbon dynasty. In 1799 the troops of the French Republic invaded Naples and converted it into the Parthenopean Republic. For Nelson's share in Neapolitan politics at this time, see NELSON. A second invasion by Napoleon (1806) ended in the proclamation of his brother Joseph as king of Naples; and, when Joseph assumed the Spanish crown in 1808, that of Naples was awarded to Joachim Murat. On the defeat and execution of Murat in 1815 the Bourbon monarch, Ferdinand IV., was restored. The insurrectionary movements of 1821 and 1848 were the forerunners of the overthrow of the Bourbon rule by Garibaldi (q.v.) and the Sardinians, and the incorporation of Naples in the kingdom of Italy (1861).

See Colletta, *History of the Kingdom of Naples* (1734-1825; Eng. trans. by S. Horner, 2 vols. Edin. 1858); Croce, *Storia del Regno di Napoli* (1924); Constance Giglioli, *Naples in 1799* (1903); and see also ITALY, SICILY, and FERDINAND I. and II.

Naples (Gr. and Lat. *Neapolis*, Ital. *Napoli*), till 1860 the capital of the kingdom of Naples (q.v.), and now chief town of Naples province (area, 350 sq. m.; pop. 1,500,000), is the largest city in Italy, and perhaps the most beautifully situated in Europe. It lies 161 miles by rail SE. of Rome. It is the seat of an archbishop. Pop. (1881) 463,172; (1921) 772,405. Naples is a naval base. Extensive improvements have been carried out in the harbour. As a port Naples has no rival in Italy except Genoa. The chief exports consist of live animals and animal products, manufactured hemp and flax, macaroni, cereals and fruits. The chief imports are cereals, metals, cottons, woollens, earthenware and glass, animals and animal foods, groceries and

chemicals. Naples has many employments but before the 20th century had few industries, and these insignificant, consisting mainly of woollen, silk, and linen manufactures, gloves, soap, perfumery, jewellery, earthenware, hats, and carriages. There were ironworks and shipbuilding-yards in other towns in the bay. New industries have since sprung up and the old have developed. The neighbourhood is the market-garden of Italy.

Its attractiveness, due not only to its site, but to its tonic and bracing climate, specially delightful in autumn and winter, and, thanks to the sea-breeze, quite tolerable in the summer-heat, has inspired the well-known proverb, 'See Naples and die.' Its charms have remained proof against innumerable sanitary drawbacks, defective drainage, impure water-supply, and the fever preserves of its poorer quarters with their subterranean dens, in course of removal since 1889. The impetus to this work was given by the fearful cholera

outbreak of September 1884, when in one night nearly 2000 people were attacked, and about 1000 of them died. Drainage-works carry the sewage to Cumæ, thus relieving the sea-margin, under the principal hotels, of the liquid poison that used to stain the water black hard-by the most frequented marine-baths, and infect the oysters moored in baskets near the shore. An aqueduct opened in 1885 furnishes pure drinking-water to every part of the city. Along the quay considerable improvements have been made—a new harbour, solid embankments, and commodious promenades following up the handsome squares, planted with trees and parterres, new streets cut through the more populous quarters, a fine embankment carried along the sea-front, and the Corso Vittorio Emanuele, a road traversing all the heights above the city.

Naples occupies the base and flanks of a hill-range rising, amphitheatre-wise, from the sea, and divided into two unequal parts by the Capodimonte, S. Elmo, and Pizzofalcone heights, the latter ending in the small island crowned by the Castel dell'Ovo. The most ancient and populous part of the city lies in the eastern crescent, and is intersected from north to south by the Via Toledo (now Via di Roma), the main historic street of Naples, more densely peopled than any other of equal space in Europe. Numerous broad streets have been built on this side of the city. A fine quay extends eastward to the Castel del Carmine. To the back of this lies the poorest and most populous quarter, now being dismantled. Westward runs the less ancient city, smaller in extent, but freer as to air and prospect, and frequented by

the more favoured classes, resident and migratory. Along the sea-margin extend public gardens and the Riviera di Chiaja, the lower boundary of the comparatively new quarters built against the slope. On the Vomero Hill, in the north-west, an extensive quarter sprang up to accommodate the inhabitants of the dismantled 'rookeries' near the harbour, for whom dwellings were also built beyond the railway station to the east of the city. Naples has a modern look, but in spite of external change still presents the same noisy, vivacious, mercurial life so astonishing and ere long so oppressive in its monotony to the new-comer from the north. From the precocious street arab to the gray-haired and vociferous mendicant, with a whole army of importunate pedlars, cabmen, newsvendors, flower-girls, and touts between, there is no pause night or day—that 'Naples never goes to bed' is indeed a scarcely exaggerated saying. The historic interest of the suburban quarters along the shore is greater than that of the city. But its poverty in Græco-Roman antiquities is made up for by its National Museum, rich in archaeological treasure-trove from Pompeii, while its splendid aquarium teems with typical specimens of the flora and fauna of the Mediterranean, and forms the exhibition-room of its Zoological Station. Of architectural interest Naples has little. Besides her five forts and four gates of mediæval construction, she has upwards of 300 churches, including the cathedral (1272-1316) of St Januarius (q.v.), whose blood is said to liquefy in the phials containing it on three yearly festivals. The university (1224), the royal palace, the catacombs, and, still more, the law-courts are worth visiting. Naples is excellently equipped with libraries: the National Library (1804), the University Library (1812), the Brancacciana (1673), are all rich in printed books and MSS. The San Carlo Theatre (chiefly for opera) is one of the largest in Italy, though much less popular than the San Carlino, sacred to 'Pulcinella' (the Italian Punch) until the picture-house drove Punch into the streets. In fine art Naples is poor—her music, in spite of her devotion to opera, adding nothing to the European repertory except *Pagliacci*; but the plaintive songs of her fishermen are as truly Mediterranean as the Venetian *barcaruole* are Adriatic.

Napoleon I., emperor of the French. Napoleon Bonaparte, the second son of Charles Bonaparte and his wife Letizia de Ramolino, was born at Ajaccio, in Corsica, on the 15th August 1769. In 1779 he entered the Royal Military School of Brienne le Château; there he remained till the autumn of 1784, when he was transferred to the Military School of Paris, according to the usual routine. An official report on him by the Inspector of Military Schools in this year speaks highly of his conduct, and notifies his great proficiency in mathematics and fair knowledge of history and geography, but says he is not well up in ornamental studies or in Latin, and, curiously enough, adds that he will make an excellent sailor. Napoleon lost his father in 1785, and the same year he was commissioned as second-lieutenant of artillery, in which capacity he served at Valence and other garrisons. He spent his periods of leave in Corsica, and appears to have wished to play the leading part in the history of his native island, showing the first signs of his ambitious and energetic character. During the critical times following the first French Revolution, he at first joined the moderate party of Paoli; but, trying for military power, though by untiring activity and

reckless audacity he succeeded in being elected lieutenant-colonel of the National Volunteers of Ajaccio, he failed in an attempt to seize that town and was obliged to return to France. Although he had forfeited his French commission by overstaying his leave, the second Revolution of 1792 was now in progress, and the new government could not spare the few trained officers whom emigration had left, and his rank was restored to him. He returned to Corsica and accompanied an expedition which unsuccessfully tried to get possession of Sardinia. The French government soon made an endeavour to crush Paoli and do away with Corsican privileges, and the islanders rallied round the patriot. Napoleon now turned against him and attempted to seize the citadel of Ajaccio for the French; but failing again, with all his relatives he fled a second time to France.

From this time onwards Napoleon looked to France for his career. The narrow horizon of his native island was no longer wide enough for him, but from its bracing mountain air and from the quick blood of his race he drew a magnetic force which imparted to his decisions and actions a rapidity and energy that carried all before them, while at the same time a power of calm calculation, of industry, and of self-control enabled him to employ his genius to the best advantage. The force of his personality was so overwhelming that in considering his career the regret must ever be present that the only principle that remained steadfast with him, and is the key to his conduct throughout, should have been the care for his own advancement, glory, and power. Napoleon now joined the army under Carteaux, which acted against the Marseillais who had declared against the National Convention and occupied Avignon. At this time he became attached to the younger Robespierre, who was a commissioner with the army, and embraced his Jacobin principles. He was shortly promoted Chef de Bataillon, and commanded the artillery at the siege of Toulon, where he highly distinguished himself, and is generally believed to have been the author of the plan of attack which led to the fall of the place. He was then promoted general of brigade.

On the fall of the Robespierres, Napoleon incurred serious danger, but was saved by powerful influence enlisted in his favour. He was, however, ordered to take command of an infantry brigade in the Army of the West. This he considered would stifle his military career, and neglecting to obey the order, he was in consequence removed from the list of employed general officers. Disgusted with his apparent lack of prospects, he was now anxious to be sent to Turkey to reorganise the Turkish artillery. But on the eve of the 13th Vendémiaire (5th October 1795) he was appointed second in command of the Army of the Interior under Barras, and did the National Convention good service next day in repelling the attack of the Sections of Paris. Influenced partly by fear and partly by appreciation of his talents, the Directory appointed General Bonaparte to the command of the Army of Italy on 23d February 1796. On 9th March he married Joséphine Tascher de la Pagerie, widow of General Vicomte Alexandre de Beauharnais, and left Paris for Italy two days later.

On joining the army Bonaparte inaugurated a new era in the wars of the Republic. Previously the leading motives had been pure patriotism and love of liberty; Bonaparte for the first time, in his proclamation on taking command, invoked the spirit of self-interest and plunder, which was to dominate the whole policy of France for the next twenty years. Evil as were the passions which he

aroused, Napoleon's great military genius flashed forth in its full brilliancy in this his first campaign. His power lay in the rapidity and boldness of his decisions, and in the untiring energy with which he carried them out, confounding his enemies by the suddenness and lightning rapidity of his blows, which never gave them time to recover. He found the French army about 36,000 strong, distributed along the crests of the mountains from Nice to Savona, and opposing 20,000 Piedmontese under Colli and 38,000 Austrians under Beaulieu. These two generals had, however, differing interests: Colli's main object was to protect Piedmont, Beaulieu's to cover Lombardy. Hence, if Bonaparte could penetrate the point of junction of the two armies, it was probable they would separate in their retreat, and could be beaten singly. He therefore attacked the centre of the allied line, and, driving back the Austrians from Montenotte on the 12th April, turned against the Piedmontese and defeated them at Millesimo the next day. Losing no time he left a division under Augereau to keep the Piedmontese in check, and led the bulk of his army against the Austrians, defeating them heavily at Dego on the 14th. The allied armies then retreated in diverging directions as expected, and Bonaparte, following the Piedmontese, beat them at Ceva and Mondovì, and forced the king of Sardinia to sign the armistice of Cherasco, leaving him free to deal with the Austrians. He crossed the Po at Piacenza on the 7th May, and obliged the Austrians to retreat to the Adda. Following them he forced the bridge of Lodi on the 11th May, and entered Milan amid the rejoicings of the people on the 15th. But his ill-omened proclamation had done its work; violence and pillage were rampant in the French army, and he could do little to restrain them. Indeed, he himself showed an example of plundering, though under more organised forms. Heavy contributions were exacted, curiosities and works of art were demanded wholesale and despatched to France; and the Directory, demoralised by the unaccustomed wealth that flowed in upon them, became fully as eager as Napoleon for fresh conquests and their accruing spoils. Insurrections followed at Pavia and in the Milanese, but were ruthlessly put down, and on the 27th May the army left Milan to follow Beaulieu to the Mincio. The Austrians defended the whole line of this river, but Napoleon, drawing the bulk of their forces northward by a feint, broke through their centre at Borghetto, and Beaulieu retreated into Tyrol, leaving the line of the Adige to Napoleon. This he at once occupied, taking Verona and Legnago from the neutral republic of Venice, whom he frightened into submission.

The Austrians still held Mantua, which Napoleon now besieged, occupying himself at the same time in consolidating his conquests. The Austrians made strenuous efforts to save the fortress. They had about 20,000 men in Mantua, and Wurmser advanced through Tyrol with 50,000 more, while the French were only some 45,000 strong including the siege corps. Wurmser moved in three columns: one descended the Adige and threatened Verona, another moving between the Adige and the Lake of Garda drove Joubert and Masséna from Rivoli and Corona, while the third under Quasdanovich moved west of the Lake of Garda and seized Brescia, threatening the French communications. Napoleon's position was very critical, but he made a rapid decision, raised the siege of Mantua, spiking his guns and destroying his stores, moved all the force he could collect against Quasdanovich, and defeated him at Lonato on the 31st July. Wurmser moving on Mantua found no enemy there, and missed being at the decisive point at the right time. Napoleon, leaving a small force

to watch Quasdanovich, turned rapidly back against the other two Austrian columns which were not yet fully united, and beat their most advanced troops at Lonato again on the 3d August and Wurmser himself at Castiglione on the 5th, driving him back into Tyrol with the loss of half his army. Mantua was again invested, but, the siege-artillery having been lost, the operations against it were reduced to a blockade. In the beginning of September Napoleon took the offensive against Wurmser, and passing boldly behind him defeated him at Bassano, cut off his retreat, and forced him to take refuge in Mantua on the 15th September. Again, at the end of October, an Austrian army of 50,000, but mostly recruits, advanced under Alvinzi. Napoleon could now dispose of from 38,000 to 40,000 men, having in the meantime formed the Cispadane Republic and raised an Italian legion which set free most of his garrisons. Alvinzi arrived before Verona, while a column under Davidovich moved by the eastern shore of the Lake of Garda. Napoleon hastily caused the positions of Rivoli and Corona to be reoccupied to check Davidovich, and moved himself by night from Verona down the right bank of the Adige, crossed it at Ronco, and came upon Alvinzi's rear. Then followed the three days' battle of Arcola, during which Napoleon had a very narrow escape, but which ended in Alvinzi's defeat and retreat on Tyrol. From Arcola Napoleon dated his firm belief in his own fortune. Once again, in January 1797, Alvinzi tried to relieve Mantua. Feinting against Legnago to deceive Napoleon, he intended to make his main advance between the Adige and the lake. But Napoleon was too skilful to take decided action without full knowledge, and keeping his reserve half-way between Rivoli and Legnago waited for more certain news. When he ascertained the direction of the real attack, he moved in full force on Rivoli and won a decisive battle there on January 14, the Austrian detachment on the Lower Adige having to lay down their arms next day at Roverbella. Wurmser capitulated at Mantua on the 2d February, Napoleon treating him with generosity. This first Italian campaign was perhaps the most skilful of all those of Napoleon. Everything was done accurately and rapidly, and without throwing away chances. Some of his later campaigns, though equally brilliant, show him acting more with the gambler's spirit, running unnecessary risks with almost a blind reliance upon his star, in the hope of obtaining results which should dazzle the world.

In political matters during this time Napoleon was acting less as a servant of the French Directory than as an independent ruler. He entirely ignored the instructions he received from Paris, levying contributions, entering into negotiations and deposing princes at his own will, and writing that he is not fighting 'for those rascals of lawyers.' His policy was in fact regulated in accordance with his own ambitious schemes; and we find him adopting a conciliatory attitude towards Rome with an eye to the future support of the church.

When his position in Italy was secured by the fall of Mantua, and by treaties with Rome and Sardinia, he prepared to advance through Carinthia and Styria on Vienna. He pushed back the Archduke Charles from the Tagliamento, and advanced till he reached Leoben in Styria on the 7th April 1797. Then Austria sued for peace, and the preliminaries of Leoben were signed on the 18th April pending the conclusion of a definite peace. But further negotiations dragged on, as Austria thought a revolution might be impending in France from which she could obtain advantage. In fact a

party was rising against the Directory, consisting mainly of moderates who were eager only for a respectable government, but containing also a few royalists. Their inclusion was fatal to the party. It gave a pretext for raising the cry that the Republic was in danger, and Angereau, sent by Napoleon to Paris, aided the Directory to carry out the *coup d'état* of the 18th Fructidor, when the Corps Législatif was surrounded by troops and the obnoxious representatives arrested. This strengthened the Directory for the moment, but was a step towards military despotism under Napoleon. Austria, seeing the Directory again firmly seated in power, became more eager for peace, the negotiations were hastened, and on 17th October 1797 the treaty of Campo-Formio was signed. By this France obtained Belgium and the Ionian Islands, Austria also acknowledging the Cisalpine Republic, and ceding to it Lombardy, and engaging to try and get the left bank of the Rhine for France from the Germanic body. As an indemnity Austria obtained Istria, Dalmatia, and the territory of the Venetian Republic, with whom, although neutral, Napoleon had managed to pick a quarrel with this end in view.

Napoleon returned to Paris on the 5th December 1797. The Directory, fearing his ambition, thought they could only keep him quiet by employing him, and gave him command of the so-called Army of England. But he was bent on the conquest of Egypt. He appears to have had something visionary in his temperament, and to have dreamed of founding a mighty empire from the standpoint of the East, the glow and glamour of which seem always to have had a certain fascination for him. He therefore employed the resources of the Army of England to prepare for an expedition to Egypt, and the Directory yielded to his wishes, partly no doubt through the desire of getting him away from France. But their aggressive policy was at the same time fast bringing on another European war. The expedition sailed from Toulon on the 19th May 1798, captured Malta from the Knights of St John by treachery, and, escaping by great luck from the British fleet under Nelson, arrived at Alexandria on the 30th June. The army was disembarked in haste, for fear lest Nelson should arrive, and on the 8th July Napoleon marched on Cairo. He defeated the Mamelukes at Chebreiss and the Pyramids, and entered Cairo on the 24th July. He then occupied himself with organising the government of Egypt, but his position was rendered very hazardous by the destruction of the French fleet on the 1st August by Nelson at the battle of the Nile, and he saw that his dream of founding an empire in the East could not be realised. He thought, however, that he might create a revolution in Syria, by the aid of which he might overthrow the Turkish power and march in triumph back to Europe through Asia Minor and Constantinople. He accordingly entered Syria in February 1799 with 12,000 men, but was brought to a standstill before St Jean d'Acre. Failing to capture that fortress, supported as it was by the British squadron under Sir Sidney Smith, in spite of the most desperate efforts, he was obliged to return to Egypt. The killing in cold blood of 2500 prisoners at Jaffa has been execrated and defended—most of them had already broken their parole; but there seems to be some doubt about the truth of the story that in his retreat Napoleon caused the sick he could not transport to be poisoned. After his return to Egypt, Napoleon defeated a Turkish army which had landed at Aboukir, but learning the reverses that had been suffered by the French arms in Europe, he resolved to leave Egypt and return to France. He embarked secretly on the 22d August, leaving a letter placing Kléber in

command of the Army of Egypt, and landed in France six weeks later.

He found matters at home in great confusion. The wars had been mismanaged, Italy was almost lost, and the government in consequence was in very bad odour. Sieyès, one of the Directors, meditated a *coup d'état*, but was at a loss for a man of action to take the lead. At this juncture Bonaparte arrived, and, though for some time there was no *rapprochement* between him and Sieyès (the latter fearing Bonaparte's masterful character, and Bonaparte uncertain what party it would be most to his advantage to join), they at length coalesced, and the revolution of the 18th Brumaire followed (9th November 1799), when the legislature was forcibly closed and a provisional executive of three consuls, Sieyès, Roger-Ducos, and Bonaparte, formed to draw up a new constitution. This was promulgated on the 13th December; the executive was vested in three consuls, Bonaparte, Cambacérès, and Lebrun, of whom Bonaparte was nominated First Consul for ten years. He was practically paramount, the two remaining consuls being ciphers, and the other institutions being so organised as to concentrate power in the executive. Sieyès became president of the senate. The governmental crisis being settled, energetic steps were taken with regard to the civil war in the west. A proclamation was issued promising religious toleration at the same time that decided military action was taken, and these measures were so successful that all was quiet at home by the end of February 1800. Then Napoleon turned his attention abroad. He made overtures for peace to England and Austria, now the only belligerents, as he wished to lull suspicion by posing as the friend of peace, not as a military ruler; but he inwardly rejoiced when they rejected his overtures.

The situation of the belligerents on the Continent was this: the Army of the Rhine under Moreau, more than 100,000 strong, was distributed along the Rhine from the Lake of Constance to Alsace, opposed to Kray, whose headquarters were at Donaueschingen in Baden; while Masséna with the Army of Italy was on the Riviera and at Genoa, opposed to an Austrian army under Melas. Napoleon intended to gain himself the chief glory of the campaign; so, giving Moreau orders to cross the Rhine but not to advance beyond a certain limit, and leaving Masséna to make head as best he could against Melas, with the result that he was besieged in Genoa and reduced to the last extremity, he prepared secretly an army of reserve near the Swiss frontier, to the command of which Berthier was ostensibly appointed. Outside and even inside France this army of reserve was looked upon as a chimera. Moreau crossed the Rhine on the 24th April and drove Kray to Ulm, but was there checked by Napoleon's instructions, according to which he also sent a division to co-operate with the army of reserve. Napoleon himself went to Geneva on the 9th May, and assuming command of this army crossed the St Bernard and reached the plains of Italy before Melas had convinced himself of the existence even of the army of reserve, and whilst his troops were scattered from Genoa to the Var. Napoleon's obvious course would now have been to move straight on Genoa, relieve Masséna, and beat in detail as many of Melas' troops as he could encounter. But this would not have been a sufficiently brilliant triumph, as the bulk of the Austrian army might have escaped; and trusting in his star he resolved to stake the existence of his army on a gambler's cast. Leaving Masséna to be starved out, he moved to the left on Milan, and occupied the whole line of the Ticino and Po as far as Piacenza, so as to cut off entirely the retreat of the Austrians. He then crossed the Po and concen-

trated as many troops as he could spare at Stradella. The strategy was brilliant, but the risk run excessive. His army was necessarily scattered, while Melas had had time to concentrate, and he was besides ignorant of the Austrian position. He sent Desaix with a column to seek information, and moved himself on Alessandria, where he found Melas. Next day, the 14th June, Melas marched out to attack the French on the plains of Marengo, and despite all Napoleon's efforts had actually defeated them, when fortunately Desaix returned, and his advance, together with a cavalry charge by Kellermann, changed defeat into victory. Melas, losing his head, signed a convention next day giving up almost all North Italy, though Marmont says that if he had fought another battle he must have won it. Napoleon returned to Paris with the glories of this astonishing campaign; but peace did not follow till Moreau, when his liberty of action was restored to him, had won the battle of Hohenlinden on 3d December 1800. Then followed the treaty of Lunéville with Germany in February 1801, the concordat with Rome in July 1801, and the treaty of Amiens with England in March 1802, so that Napoleon was able to figure as the restorer of peace to the world. He then devoted himself to the reconstruction of the civil institutions of France, employing in this great work the best talent that he could find, and impressing on their labours the stamp of his own genius. The institutions then created, which still remain for the most part, were the restored church, the judicial system, the codes, the system of local government, the university, the Bank of France, and the Legion of Honour.

France at this period, sick of the failure of republican government, was gradually veering towards monarchy, and Napoleon knew how to take advantage of events to strengthen his position, and in due time establish his own dynasty. The plot of Nivose (24th December 1800), when his life was threatened by a bomb, gave him a pretext for arresting and transporting 130 members of the Jacobin party, with which he had long since broken; and after the conclusion of the peace of Amiens a great step was taken when, as a mark of public gratitude for the pacification of the world, he was elected First Consul for life. But though he desired the credit of making peace, so as to enable him to establish his authority over France, when that end was secured he became again eager for war, with a view to further extension of his power. He also desired to humble England, a desire that led to the rupture of the peace of Amiens in 1803. The immediate causes of this rupture were his aggressions in Holland, in the Cisalpine Republic, in Genoa, and Piedmont, and his monstrous demand that England should suppress every print that dared to criticise his actions, and drive all French refugees from her shores. Having thus forced England to resume hostilities, he made vast preparations for her invasion, at the same time taking the first step towards establishing his ascendancy in Germany by seizing Hanover. The assumption of the crown soon followed, Napoleon preparing the way with consummate cunning. He rid himself of Moreau, his most dangerous rival, by accusing him of conspiring with the royalists, into whom he then struck terror by the execution of the Duc d'Enghien. He thus succeeded in inspiring even republicans with the conviction that the best way of preventing the inauguration of a new reign of terror was by confirming his position. He chose the title of emperor as least obnoxious to the republican feeling of the army, and the change was made by a decree of the senate of the 18th May 1804.

Preparations for the invasion of England had been steadily proceeding, but Napoleon's aggressive

demeanour after becoming emperor alarmed the European cabinets, so that Pitt was able to revive the coalition, and in 1805 Napoleon found himself at war with Russia and Austria, as well as with England. Forced by England's naval supremacy to abandon the notion of invasion, he suddenly changed front in August 1805, and led his armies through Hanover and the smaller German states, disregarding the neutrality even of Prussia herself, and reached the Danube in rear of the Austrian army under Mack, which was at Ulm. The surprise was complete; Mack surrendered on the 19th October, and Napoleon then marched on Vienna, which he entered on the 13th November. But his position was critical. The Archduke Charles was approaching from Hungary, a Russian army was entering Moravia, and Prussia, incensed at the violation of her territory, undertook to put 180,000 men in the field if her terms were refused. A short delay would have surrounded Napoleon with his enemies, but the tsar was impatient, and the Russian army, with a small contingent of Austrians, encountered Napoleon at Austerlitz, 2d December 1805, and was signally defeated. This caused the break-up of the coalition; the Holy Roman Empire came to an end, the Confederation of the Rhine was formed under French protection, and the Napoleonic empire was firmly established. Napoleon then entered into negotiations for peace with Russia and England, endeavouring to conciliate those powers at the expense of Prussia. The negotiations failed, but Prussia was mortally offended, and mobilised her army in August 1806, about which time Russia finally rejected the treaty with France. Napoleon acted with his usual promptitude, and advanced against Prussia before she could get help either from England or Russia. Although the rank and file of the Prussian armies was good, their generals were antiquated, and Napoleon crushed them at Jena and Auerstädt on the 14th October, and entered Berlin on the 27th. He had then to carry on a stubbornly-contested campaign with Russia. An indecisive battle at Eylau was followed by a hardly-earned French victory at Friedland, 14th June 1807, and the peace of Tilsit ensued, by which Prussia lost half her territory, and had to submit to various humiliating conditions, while Russia escaped easily, and indeed got a share of the spoils.

Napoleon was now at the zenith of his power; he was the arbiter of Europe and the paramount head of a confederation of princes, among whom the members of his own family occupied several thrones. To reward his partisans he at this time created a new noblesse, and lavished upon them the public money. Full of inveterate hostility to England, Napoleon endeavoured to cripple her by the so-called Continental System (q.v.), by which all the states under his influence engaged to close their ports to English ships, and he also tried to combine all the European navies against her; but England, perceiving his aim, took the initiative and herself seized the Danish fleet. The emperor also turned his eyes to the Peninsula, where the dissolute conduct of the Queen of Spain and the intrigues of 'the Prince of the Peace' (see *ALCUDIA*) gave him an opportunity. He sent an army under Junot to Portugal, and another to Spain, which, under Murat, took Madrid. Napoleon then procured the abdication of the king of Spain and placed his brother Joseph on the vacant throne. But he did not foresee the consequences. The spirit of the nation was roused, and a formidable insurrection broke out, while a British army, under Sir Arthur Wellesley, landed in Portugal, defeated Junot at Vimeiro, and forced him to sign the Convention of Cintra, evacuating Portugal. So began the Peninsular War (q.v.) which for the future was to paralyse half Napoleon's strength.

In Germany also a spirit of revolt against his tyranny was rising, Austria at first taking the lead, and this brought on the war of 1809 against that power. Prussia, already beginning to recover her strength under the military system of Scharnhorst and Stein (see SCHARNHORST, STEIN), was hostile to Napoleon in sentiment, but was kept down by the pressure of Russia. Napoleon declared war on the pretext that Austria was arming, and marching through Bavaria drove the Austrians out of Ratisbon, and entered Vienna on the 13th May. Eugène Beauharnais, at the head of the Army of Italy, drove the Austrians before him into Hungary, defeated them at Raab, and joined Napoleon. The emperor then tried to cross the Danube, but was checked at Aspern and obliged to retire to the island of Lobau. Five weeks of preparation then followed, the peasant war under Hofer being carried on in Tyrol, and then Napoleon made a fresh and successful attempt to cross the Danube, and won the battle of Wagram on the 5th and 6th July. This was followed by the armistice of Znaim and the treaty of Schönbrunn, October 20, 1809, by which he obtained a heavy indemnity in money and considerable accession of territory in Carniola, Carinthia, Croatia, and Galicia. But he mortally offended the tsar by giving a large portion of the ceded territory of Galicia to the duchy of Warsaw—i.e. to Poland.

On the 16th December 1809 Napoleon, desirous of an heir, divorced Joséphine, who was childless, and married on the 1st April 1810 the Archduchess Maria Louisa of Austria. He had no doubt the wish also to get a footing in the circle of the legitimate reigning families of Europe. A son, to whom the title of King of Rome was given, was born on March 20, 1811.

Still bent on the humiliation of England, Napoleon now tried to effect his purpose by increasing the stringency of the Continental System, but this ended in bringing him into conflict with Russia. He first annexed the kingdoms of Holland and Westphalia, to give him command of their seaboard, and then prohibited English trade even when carried in neutral bottoms. The tsar, already estranged by Napoleon's alliance with Austria and his conduct as regards Poland, refused to adopt this policy, and the relations between them gradually became so strained that war was inevitable, and Napoleon took the momentous resolve to invade Russia. With Maria Louisa, he arrived at Dresden on the 16th May 1812, and was there greeted by the emperor of Austria, the king of Prussia, and other sovereigns. His army for this gigantic enterprise numbered about 600,000, including French, Germans, and Italians. He crossed the Niemen on the 24th June, reaching Vilna, which was evacuated by the Russians, on the 28th; and he remained at Vilna till the 16th July, hesitating to take the final resolution to invade the heart of Russia. He made overtures for peace to the tsar, who refused to treat as long as an enemy remained on Russian soil. Foiled here Napoleon at last decided to go on with his enterprise; so he advanced, and at first the Russians were in no condition to meet him, their forces being scattered. If Napoleon could have advanced rapidly to Smolensk, he might have cut the Russian forces in two, but his vast host appears to have been unmanageable. Barclay de Tolly and Bagration succeeded in uniting at Smolensk, but were driven from it on the 18th August after an obstinate defence. At Smolensk Napoleon again hesitated as to whether he should go into winter-quarters, but eventually decided to press on to Moscow, trusting to the moral effect of the fall of the ancient capital. It seems as if, while his superstitious belief in his star still remained, bodily ailments had caused a

deterioration in his power of rapid decision and in his energy of action. Meanwhile, great discontent had been caused in Russia by the continued retreat of the armies. Kutusoff was appointed to the chief command, and stood to fight at Borodino on September 6. Napoleon won the battle, but with unwonted and misplaced caution refused to engage his Guard, and the victory was almost fruitless.

He entered Moscow on the 14th September, and fire broke out the next night, the first effect of which was still further to alarm the Russians, who believed it to be the work of the French. The fire raged fiercely till the 20th, and a great part of the city was burned to the ground. Had the victory of Borodino been more decisive the tsar might now have yielded; but as it was he listened to the advice of Stein and Sir R. Wilson and refused to treat, thus putting Napoleon in a dilemma. His plans were always made on the basis of immediate success, and the course to be adopted in case of failure was not considered. Again he hesitated, with the result that when at last he resolved to retire from Moscow the winter, coming earlier than usual, upset his calculations, and the miseries of that terrible retreat followed. He left Moscow on the 18th October, and, reaching the Beresina with but 12,000 men, was joined there by Oudinot and Victor, who had been holding the line of the Dwina, with 18,000. His passage of the river was opposed, but he succeeded in crossing, and on the 6th December the miserable remnant of the Grand Army reached Vilna. Macdonald, Reynier, and Schwarzenberg, with 100,000 men, on the Polish frontier and in the Baltic provinces, were safe, but this was the whole available remnant of the 600,000 with which the campaign commenced. It might have been expected that Napoleon would now be anxious for peace, but his haughty spirit could not brook any diminution of his prestige, and, determining to try and efface the past with fresh triumphs, he returned to Paris to raise new levies. The tsar fully understood that no half-measures would be of any avail, but that he must follow up what had been begun and carry the war into Germany the next year, rousing the Germans to his aid. On the 30th December 1812 York, commander of the Prussian auxiliaries, on his own authority concluded a convention with the Russians, and declared his corps meanwhile neutral. Prussia entered an alliance with Russia on 26th February 1813, and declared war on France (13th March). Saxony, long disaffected, did not actually join the allies till 18th October, as the king had not dared to desert Napoleon. Austria and the middle states still clung to Napoleon.

Napoleon left Paris for Mainz on the 15th April 1813, his object being Dresden, which was held by the tsar and the king of Prussia. Eugène Beauharnais was on the Lower Saale with 70,000 men, and Napoleon, with 150,000 men, well officered, though raw and short of cavalry, moved to meet him by way of Erfurt. Davout was holding down insurrection in north Germany with 30,000. The allies at first had only 100,000 available, the process of calling out and drilling the people being slow. Napoleon moved on Leipzig, and won the battle of Lützen on the 2d May, which restored Dresden to the king of Saxony. He then followed the allies, beat them, though with heavy loss, at Bautzen on the 20th and 21st May, and forced them to retire into Silesia. The armistice of Poischwitz, signed on the 4th of June, closed the first period of the campaign. Austria then asked for certain concessions, which if Napoleon had granted he might have checkmated the coalition of Prussia and Russia; but he seems to have been unable to bring himself to accede,

and contemplated rather war with Prussia, Russia, and Austria combined, to say nothing of England, which was still carrying on the war in the Peninsula. A treaty was signed at Reichenbach on the 14th June, by which Austria engaged as mediating power to offer conditions of peace to Napoleon and to declare war on him in case of refusal. The conditions offered were that he should withdraw from north-west Germany, dissolve the duchy of Warsaw, and cede Illyria. These terms were very moderate, but Napoleon seems to have thought his position insecure without fresh success in war, and procrastinated. An ultimatum was delivered to him on August 8th to which he paid no attention; so on the night of the 10th to 11th August the armistice was declared at an end, and the drama swept rapidly to its crisis.

Napoleon had now 400,000 men along the Elbe from Bohemia to its mouth, but his position was weakened by the adhesion of Austria to the coalition, as she massed her troops in Bohemia, threatening Dresden and his communications. The allies had nearly 500,000 men in three armies, the Austrian under Schwarzenberg in Bohemia, the old Prusso-Russian under Blücher in Silesia, and the bulk of the Prussian force under Bernadotte in Brandenburg. The French armies were discouraged, and the allies enthusiastic; but the latter had difficulties to contend with from their heterogeneous composition and diversity of interests. The campaign opened with varying fortune. A blow at Berlin was parried by Bülow at Gross-Beeren on August 23. Napoleon himself forced Blücher back to the Katzbach, but had to retire again to defend Dresden from the Austrians; and his lieutenant Macdonald was defeated in the battle of the Katzbach on the 26th August. Napoleon inflicted a crushing defeat on the Austrians before Dresden on the 27th, but, while preparing to cut off their retreat, was disturbed by the news of Gross-Beeren and the Katzbach and by sudden illness, and at Kulm lost Vandamme with 20,000 men. September was spent in fruitless marches, now into Bohemia, now into Silesia, and towards the end of the month the allies began their converging march on their preconceived rendezvous at Leipzig. At the same time the Confederation of the Rhine began to dissolve. The kingdom of Westphalia was upset on the 1st October, and on the 8th Bavaria joined Austria. The toils were closing round Napoleon, and between the 14th and 19th October he was crushed in that battle of the Titans at Leipzig, and, brushing aside the Bavarians who tried to stop him at Hanau, on the 1st November led back the remnant of his army, some 70,000 strong, across the Rhine at Mainz.

The allies now made overtures for peace on the basis of natural frontiers, which would have left France the fruits of the first Revolution—viz. Belgium, the left bank of the Rhine, Savoy, and Nice; but Napoleon could not be content with such curtailment of his power. Evading at first the proposal, he would have accepted it, but with suspicious qualifications, when too late. The invasion of France followed. The allies issued on the 1st December a manifesto saying they were waging war against Napoleon alone, and advanced with three separate armies. Schwarzenberg led the Austrians through Switzerland, Blücher crossed the Middle Rhine towards Nancy, while the northern army passed through Holland. Napoleon had yet hopes of success on account of the forces he still had in the German fortresses, the mutual jealousies of the allies, his connection with the emperor of Austria, and the patriotism which would be aroused in France by invasion. But the allies gave him no time to utilise these influences, and Paris was not fortified. Napoleon carried on a

campaign full of genius, gaining what advantage he could from the separation of his enemies. He attacked Blücher and won four battles in four days at Champaubert (February 10, 1814), Montmirail (11th), Château-Thierry (12th), and Vauchamps (13th). These successes would have enabled him to make a reasonable peace, but his personal position forbade this, and he tried subterfuge and delay. The allies, however, were not to be trifled with, and in the beginning of March signed the treaty of Chaumont, which bound them each to keep 150,000 men on foot for twenty years. The battles of Craonne and Laon followed, in which Napoleon held his own, but saw his resources dwindle. On the 18th March the conferences at Chatillon came to an end, and on the 24th the allies determined to march on Paris. Marmont and Mortier, with less than 30,000 men, could make no head against them, while Napoleon himself tried a fruitless diversion against their communications. Joseph Bonaparte withdrew Maria Louisa and the king of Rome to Tours. On the 30th March the allies attacked Paris on three sides, and in the afternoon the French marshals offered to capitulate. Napoleon, when he learned the real state of affairs, hurried up in rear of the allies, but was too late, and had to fall back to Fontainebleau. His position was desperate, and to add to his difficulties Wellington, whose career of success had gradually cleared the French out of the Peninsula, had now led his victorious army across the Pyrenees into France itself.

Napoleon therefore at first offered to abdicate in favour of his son, but, when he found that would not be sufficient, he signed an unconditional abdication on the 11th April 1814. He was given the sovereignty of the island of Elba, and the Bourbons in the person of Louis XVIII. were restored to the throne of France. But the condition of affairs was very precarious. The return of the Bourbons was most unpopular. It indeed restored the parliament, but it unsettled the position of public men and the title to estates. The army was disgusted at the appointment to commands of emigrés who had fought against France. The church began to cause alarm to the holders of national property; and by the release of prisoners and the return of the garrisons of German fortresses very large numbers of Napoleonic soldiers became dispersed over France. The coalition, too, broke up, and fresh alliances began to be sought with a view to check the aggressive spirit which Russia seemed inclined to manifest. Altogether affairs in Europe and France were in such a state as to make it not impossible that the magic of Napoleon's name might replace him in power. He accordingly resolved on making the attempt, left Elba on February 26, 1815, and landed on the French coast on the 1st March. On the 20th he entered Paris, having been joined by the army. He had the advantage of being able to appear as the liberator of France from the yoke put upon her by foreigners, but he could only re-establish his position in the face of the rest of Europe by war, and he was not quite the Napoleon of old, for his physical powers had declined, he had become stout, and had attacks of illness, sleepiness, and indolence. He had been epileptic from his youth. His mind and genius were unimpaired, and his conception of the Waterloo campaign was clear and brilliant as of yore, but the execution failed.

Europe had declared war against him, and a new coalition had been formed, but only two armies were immediately ready to take the field; a mixed force under the Duke of Wellington in Belgium, and a Prussian army under Blücher in the Rhine provinces. The English army had its base on the sea, and the Prussian on the Rhine, so that they

had diverging lines of operation. Napoleon's idea was to strike suddenly at their point of junction before they could concentrate, push in between them, drive them apart, and then defeat each separately. The plan was unexceptionable, resembling that of his first campaign in 1796, and the opening moves were successfully carried out. Napoleon left Paris on the 12th June, his army being then écheloned between Paris and the Belgian frontier, so that the point where the blow would fall was still doubtful. On the 15th he occupied Charleroi, and was between the two allied armies, and on the 16th he defeated Blücher at Ligny before Wellington could come to his assistance. So far all had gone well with him; but now apparently his energy was not sufficient to cope rapidly with the difficulties that no doubt beset him through the shortcomings of his staff, and the spirit of mutual distrust that reigned among his officers. He did nothing till the morning of the 17th, and it was not till 2 P.M. that he sent Grouchy with 33,000 men to follow the Prussians in the supposed direction of their retreat towards Liège, and keep them at a distance whilst he turned against Wellington. But he had lost his opportunity; the wasted hours had enabled the Prussians to disappear, and he did not know the fact that Blücher had taken the resolution to move on Wavre, giving up his own communications in order to reunite with Wellington. The latter had retired to a previously-chosen position at Mont St Jean, and received Blücher's promise to lead his army to his assistance. So on the 18th, when Napoleon attacked the Duke, unknown to him the bulk of the Prussian army was hastening up on his right flank while Grouchy was fruitlessly engaged with the Prussian rear-guard only. This led to the crowning defeat of Waterloo, where Napoleon's fortunes were finally wrecked. He fled to Paris, and abdicated for the last time on 22d June; and, finding it impossible to escape from France, he surrendered to Captain Maitland of the *Bellerophon* at Rochefort on the 15th July. He was banished by the British government to St Helena, where he arrived on the 15th October 1815, and died there of cancer of the stomach on the 5th May 1821.

The literature referring to Napoleon may be divided into three categories: First, books dealing with his military and political career by writers contemporary with him or nearly so, such as Thiers' *Histoire du Consulat et de l'Empire*; Jomini's *Vie politique et militaire de Napoléon* (Eng. trans. 1885); Montholon and Gourgaud's *Mémoires pour servir à l'Histoire de France sous Napoléon*; and the memoirs of his generals, such as Marmont, Masséna, and Suchet. Secondly, books touching his private life by contemporaries, such as Bourrienne's *Mémoires of Napoleon Bonaparte*; Las Cases' *Journal of Private Life and Conversations of Napoleon at St Helena*; Forsyth's *History of the Captivity of Napoleon at St Helena, from Letters and Journals of Sir Hudson Lowe*; O'Meara's *Napoleon at St Helena*. In contrast to these two classes, both inevitably one-sided, are works written in a more critical spirit, such as those by Lanfrey, Jung, Guillois, Masson, Fournier, in France, with the relevant part of Taine, and those by Seeley, O'Connor Morris (1893), Lord Wolseley (1895), W. M. Sloane (1896-97), Lord Rosebery (1900), Fisher (1903), Hudson (1915), and specially the *Life of Napoleon* (2 vols. 1902; 4th ed. 1904) and other books by J. Holland Rose. See also BONAPARTE, CODE NAPOLEON, FRANCE, JOSÉPHINE, WATERLOO, WELLINGTON, PARIS.

Napoleon II., king of Rome (1811-32), was the son of Napoleon I. and Maria Louisa (q.v.).

Napoleon III., by name CHARLES LOUIS NAPOLEON BONAPARTE, the second emperor of the French, was born at Paris on the 20th of April 1808. His father was Louis Bonaparte, king of Holland, brother of the first emperor, and his mother Hortense Beauharnais, Napoleon I.'s stepdaughter (see BONAPARTE). Louis Napoleon and

his elder brothers were heirs-presumptive to the imperial throne till the birth of a son to the emperor cast them into a secondary position, whence Louis Napoleon, the only survivor, was drawn in 1832, at the death of Napoleon's only son, to become head of the House of Napoleon. That house, astoundingly risen from the nursery of a Corsican lawyer's wife to imperial and royal thrones, thrust back into private life after a complete mastery in Europe, was again raised to imperial dignity in the person of Napoleon III., only to return to obscurity in the midst of appalling disasters; and it failed to present one of the most truly tragic dramas of all time through the want of real grandeur in both Napoleons and in almost all their blood. Had the nephew been born a scion of the Bourbon house, the part of Louis-Philippe might have been his. But brought up by his mother from the year 1815, precluded by exile and imprisonment till he was far advanced in the years of manhood from learning practical politics, he became a theorist in statecraft and a brooder on the Napoleonic legend which was his only claim to the attention of the nation. He received his early education at his mother's residence, the castle of Arenenberg, in Switzerland, on the borders of the Lake of Constance. Sent to the gymnasium at Augsburg, he not only acquired there, as well as from the prolonged German surroundings of his private life, a marked German accent, but also developed those features in his individual character which were most akin to the sluggishness of his temperament—uncertainty and indefiniteness of thought, philosophic dreaminess laming every conviction, ambition touched with fatalism firing a morally indifferent soul.

Switzerland was the real foster-mother of the brighter and healthier side of his nature. Had he been practical and a man of rectitude, he could have extracted from his political and social experience of that country principles sufficiently clear and wise to prove themselves the palladium of his later reign. There he developed his aptitude for military science: he followed the courses of instruction given to the Swiss militia officers. Fairly competent in artillery, in engineering, in the exact sciences, in history, and in athletic exercises, he wrote and published at Zurich (1836) a *Manuel d'Artillerie*. He hastened with his elder brother Louis into Italy in 1830 to assist the province of Romagna in its revolt against pontifical rule, an expedition in which Louis perished of fever, and he was himself severely stricken, but was nursed out of danger by his tender mother. This expedition, though proving that he could act with energy in the discharge of Bonapartist responsibility, was a mere episode in that Swiss period of his life, extending from 1824 to 1836, in which he was exclusively a student and a writer. When at the death of the Duke of Reichstadt he became the head of that rootless growth, the Napoleonic dynasty, he sought as a pretender to lean less on any concrete historical claim to the throne of France than on the partiality of the French to a vainglorious rule, and on the intellectual interest with which he, as a man of letters, could invest the so-called Napoleonic ideas. For sixteen years he sued for the hand of France and the attention of the world, interrupting twice the method of literary courtship to make personal raids upon the kingdom of Louis-Philippe. He had indeed a fair chance. Outside of France, nationalities whose emancipation had been planned by Napoleon I., such as Poland, looked to him to effect their long-deferred liberty (1831). In France he was an outlaw, because a formidable rival to Legitimacy; in the struggle between the junior branch of the Bourbon dynasty and the forces at work since the

Revolution, the Bonapartists had a permanent power of intervention and might enlist as their own partisans the masses of Frenchmen who were lukewarm politicians. Moreover, Napoleon I.'s utter failure as an international politician had in no wise shaken the organisation he had given to France; his home legislation had become part and parcel of the nation; French law, French public education, French military institutions, the joint restoration of state and church stood forth as his lasting work.

Almost a stranger to France in nurture of thought and tone of mind, an adventurer rather than a pretender, a philosopher rather than a man of action, taciturn, speculative, driven from within by a set motive rooted in a fixed idea, absorbed with German mysticism and Italian wiliness in a career so fateful to his mind that moral briding could not avail at its turning-point, a philanthropist in some of his dreams, an idealist in some of his deeds, the heir of the French Cæsar drifted to his destiny, not without some vigour and brightness, a victim to the alleged mission of his race, to which he was enslaved as by hypnotic suggestion. He published in 1832-36 his *Réveries politiques, Projet de Constitution, and Considérations politiques et Militaires sur la Suisse*. In 1836, speculating on the instability of Louis-Philippe's throne, the disaffection of some of the middle classes, the general favour of his semi-socialistic theories with the advanced parties, and the unspent prestige of Napoleon I., he put his chances to a premature test by appearing among the military at Strasburg, hoping to bribe them into his service by the prospect of their resuming the paramount position which soldiers could not but occupy in a Napoleonic state. The rash young man was easily overpowered and conveyed to America, without being brought to trial. Being under no pledge to stay in America, Louis Napoleon returned to Europe on hearing of his mother's illness. He found her dying; two months later he received her last sighs (3d October 1837). Although the affair of Strasburg had naturally enough caused many people to doubt the talent and the judgment of Louis Napoleon, still Louis-Philippe, who was politically an extremely timid monarch, dreaded some new conspiracy; the French government demanded of Switzerland the expulsion of the obnoxious prince, M. Molé actually enjoining the French ambassador to demand his passports, in case of a refusal. Switzerland had neither the right nor the wish to expel, and was on the point of going to war for the distinguished refugee (who was, in fact, a Swiss citizen) when he resolved to prevent a rupture by leaving his adopted country. He now proceeded to England, and settled in London. With certain members of the British aristocracy he came to live on a footing of considerable intimacy, and he was also an object of languid wonder and interest to the community generally, but he impressed nobody with a belief in his future and his genius; nay, Englishmen erred so far as to suppose that the 'silent man' was merely 'dull.' In 1838 he published in London his *Idées Napoléoniennes*, which, read in the light of subsequent events, are very significant. Europe generally regarded them as idle dreams; but in France the book went through numerous editions. In 1839 Louis Napoleon was in Scotland, and took part in the celebrated Eglinton tournament. Next year (1840) he made his second attempt on the throne of France at Boulogne. It was as grotesque a failure as the one at Strasburg. Captured on the shore, while endeavouring to make his escape to the vessel that had brought him from England, Louis Napoleon was now brought to trial, and condemned to perpetual imprisonment in the fortress of Ham. Here he continued his Bonapartist

propaganda by writing *Aux Mânes de l'Empereur, Fragments Historiques, Analyse de la Question de la Suisse, Réponse à M. de Lamartine, Extinction du Paupérisme, &c.*; and actually took part in editing the *Dictionnaire de la Conversation*, a valuable French encyclopædia. After an imprisonment of more than five years, spent in patient meditation, he made his escape (25th May 1846), by the help of Dr Conneau, in the disguise of a workman, and gained the Belgian frontier, whence he returned to England.

The revolution of February (1848) was a victory of the working-men to whom some of his political theories were especially addressed; he hurried back to France as a virtual nominee of the *Fourth Estate*, or working-classes in town and country—an embarrassing position, from the obligations of which the smashing up of the Parisian socialists by the forces of General Cavaignac released the future emperor. Being elected deputy for Paris and three other departments, he took his seat in the Constituent Assembly, 13th June 1848. On the 15th he resigned his seat and left France. Recalled in the following September by a quintuple election, he once more appeared in the Assembly and commenced his candidature for the presidency. The direct election of the head of the state by the people, intended as a republican institution, proved itself to be a stepping-stone to Cæsarism, as Louis Napoleon's peculiar conception of a modern imperial democracy is called; in the constitutional history of the second empire such appeals to universal suffrage bear the name of *plébiscites*. Out of seven and a half million of votes 5,562,834 were recorded for Prince Louis Napoleon; General Cavaignac, his genuine republican competitor, obtaining only 1,469,166.

On the 20th December he took the oath of allegiance to the Republic. For a few days concord seemed established between the different political parties in the Assembly; but the beginning of the year 1849 witnessed the commencement of a series of struggles between the president and his friends on the one side and the majority of the Assembly on the other—the latter being justly penetrated with the conviction that Louis Napoleon was not devoted to the interests of the Republic, but to his own. He became practically a traitor to his republican oath when, in league with monarchical Austria and the king of Naples, he put down the republican movement in Rome. Then he committed the command of the army to hands devoted to him, he established his personal supporters in posts of honour and influence, he gained by frequent visits the favour of the provincial towns, and by acts of liberality and clemency kept that of the people. He paraded as a protector of popular rights and of national prosperity, laying to the door of the Assembly the deficiencies in his government. Resolved to transform his tenure of power by periodical election into a life-long one, he was hampered by the National Assembly; and, with the example of his uncle's *coup d'état* (18th Brumaire 1799) before him, he deliberately threw off the mask of a constitutional president, forswore his formal oath, and became a traitor to all society. From that moment a perpetual misunderstanding, badly cloaked by material prosperity and military glory, underlay Napoleon's relation to the French and to Europe generally. His methods of government belonged to no acknowledged régime.

He whom Victor Hugo satirically called Napoleon-le-Petit fatuously chose the anniversary of the battle of Austerlitz and of Napoleon I.'s coronation to rid himself by arms of the National Assembly, to make himself absolute ruler with the help of the military, and to muzzle all parliamentary opposition (2d December 1851). Imprison-

ment, banishment, deportation, the bloody repression of popular rebellion marked this black day's work, in which the president was assisted by Morny, Maupas, and St Arnaud. France, whether wearied of the incompetent Democrats, or (as Kinglake supposes) 'cowed' by the terrible audacity of the president, appeared to acquiesce in his act; for when the vote was taken upon it on the 20th and 21st of the same month, he was re-elected for ten years, with all the powers he demanded, by more than 7,000,000 suffrages. The imperial title was assumed exactly a year after the *coup d'état*, in accordance with another plebiscitary expression of the people's will.

An unlawful empire was now legally established. Men of astuteness and mediocrity took the helm of the state. The parliamentary trappings of the first empire were brought out. Resting on such artificial props as the army and police, Napoleon III. boasted that he was the upholder of law and order. Political parties were either demoralised or broken. He gagged the press, awed the *bourgeoisie*, and courted the clergy to win the peasantry. Liberals accepted him for fear of the Socialists; the Socialists applauded his plunder of the Orleans family; his duly-rewarded parasitic supporters, such as Jean Fialin, made Vicomte de Persigny, clung to him as to the fount of all honour and profit; foreign monarchies accepted him as a welcome ally in the struggle against liberalism. But unlike his uncle he did not seek matrimonial alliance with the old royal houses. He liked to profess himself the Cæsar of the people, and led to the altar Eugénie de Montijo (1826-1920), a Spanish countess of ordinary blue blood. He sought to gain international acceptance for the just, but in his mouth sophistical, doctrine as to the right of peoples to choose their own masters, availing himself of it in the annexation of Savoy and Nice to France, in his Mexican intervention, and in his handling of the Italian question. At home he kept the people well in hand by an active economic policy. The price of bread was regulated, public works occupied and enriched the workingmen in towns, while others were undertaken to protect and enhance in value the property of the peasantry. The complete remodelling of Paris under the direction of Baron Haussmann raised considerably the value of house-property, and by the opening of a network of thoroughfares suitable for the manœuvres of artillery and cavalry reduced to a minimum the risk arising from insurrectionary movements. The holding of international exhibitions and the signing of treaties of commerce with foreign states acted as a further inducement to internal peace; but the formation of unscrupulous financial, court, and clergy cliques was an ugly blot on this picture of a purely material prosperity.

To the blandishments of work and wealth at home Napoleon III. added the charm of a brilliant foreign policy. We need not dwell on the Crimean war, the campaign in Lombardy against Austria, to which Napoleon was somewhat paradoxically encouraged by the murderous attack of Orsini on his person, the expeditions to Mexico and to China. In all those undertakings Napoleon enjoyed the support if not always the actual co-operation of Great Britain. To Prussia his relations were of a very different kind, a mixture of jealousy and patronage which boded ill for France in the event of an actual conflict.

At the death of Morny in 1865 the soothing effect of Napoleon's measures and also his power to control the nation were well-nigh spent. Again the spirit of France stirred abroad. Napoleon's book, *La Vie de Cæsar*, which he wrote to extol his own methods of government under the guise of honouring Cæsar, met with loud protests. Forewarned,

Napoleon reorganised his army, set himself up more proudly as an arbiter in Europe in order to flatter his subjects, and took a more conciliatory attitude to liberalism. His concessions at home were taken advantage of to set up a regular journalistic and parliamentary opposition. In 1869 the Liberal deputy Ollivier was granted a personal interview that he might explain to the emperor the wishes of the people, and Rouher, Napoleon's prime-minister, an advocate of absolutism, was dismissed from office. New men were called into power with Ollivier to liberalise the constitution. Some wrong-headed Bonapartists suggested another *coup d'état* against the Legislative Assembly, now leavened with opposition. Napoleon was firm enough to resist such nefarious counsels, and appears to have been fairly sincere in his latter-day liberalism. That it was not yet too late to stem the tide of discontent was shown by the result of another plebiscite (the fourth), by which Napoleon's new parliamentary scheme was sanctioned by 7½ million votes (8th May 1870). But burdened as he was by a new policy at home, by financial embarrassments and worries in his own family, in ignorance of the corruption that existed in his ministry of war, he sought in foreign affairs a diversion to his troubles, and thus brought himself all of a sudden to the edge of the abyss. For the Franco-German war, see FRANCE.

Napoleon III. surrendered himself a prisoner at Sedan in September. Till the conclusion of peace he was confined at Wilhelmshöhe. In March 1871 he joined the empress at Chislehurst, Kent, and resided there till his death on 9th January 1873.—His son, Eugène Louis Jean Joseph, Prince Imperial of France, was born 16th March 1856. He was in the field with his father in 1870, but after the fall of Sedan escaped to England, where he entered the Woolwich Military Academy, and in 1875 completed with distinction a regular course of study. Volunteering to serve with the English artillery in the Zulu campaign of 1879, he was killed on 1st June, when reconnoitring, by a party of Zulus in ambush.

See the apologetic *Life* by Blanchard Jerrold (3 vols. 1874-77), and that by Archibald Forbes (1898); Delord, *Histoire du Second Empire* (6 vols. Paris, 1869-75); Simpson, *Die Beziehungen Napoleon III. zu Preussen* (1882); C. E. de Maupas, *Story of the Coup d'État* (Eng. trans. 2 vols. 1884); Hugo's *Hist. d'un Crime* (1877); books by F. A. Simpson (1923, 1925); Ollivier's *L'Empire Libéral* (1894 et seq.); books on his Empress and Court by Edward Legge (1910-12); and Filon's *Le Prince Impérial* (1912).

Napoleon, PRINCE. See BONAPARTE.

Napoleon. See LOUIS D'OR.

Napoleon, a round game at cards. Five cards are dealt to each player. Each in turn declares the number of tricks he will stand for, or whether he will pass. When a declaration is made subsequent players must stand for more tricks or pass. If *Nap* (all five tricks) is declared, no further declaration is made. The stand-hand leads; the card he first leads makes the trump suit. If the stand-hand wins the number of tricks he stood for, he receives so much for each trick from each of the other players. If he fails he similarly has to pay all round. If *Nap* is declared and won, the stand-hand receives ten (or twelve) all round; if lost, he only pays five (or six). Sometimes this rule applies to four tricks, when *Nap* receives triple and only pays single.

Napoleona (once called *Belvisia*), a tropical African genus of myrtaceous (or lecythidaceous) plants, of which *N. imperialis* is a small tree with showy red, white, or blue flowers, and a fruit resembling a pomegranate.

Narbada. See NERBUDDA.

Narbonne, a town in the French department of Aude, on the La Robine branch of the Canal du Midi, 8 miles from the Mediterranean and 93 by rail ESE. of Toulouse. The removal since 1865 of the fortifications has been an improvement, but the place remains dirty and unattractive, with only three noteworthy buildings. These are the Romanesque church of St Paul (1229); the quondam cathedral of St Just (1272-1332), only the fine Gothic choir of which, 131 feet high, has been completed; and the former archbishop's palace, now the hôtel-de-ville, in one of whose three old towers Louis XIII. in 1642 signed the order to arrest Cinq Mars, and in which are a good museum, a library, and a picture-gallery. The white heather-honey of Narbonne maintains its ancient celebrity; the wine is chiefly used for blending purposes. Pop. (1921) 28,956. Narbonne is the *Narbo Martius* of the Romans, their earliest colony (118 B.C.) beyond the Alps; and, situated on the high-road to Spain and the basin of the Garonne, was a place of great commercial importance. Under Tiberius it flourished greatly, its schools for a long time rivalling those of Rome. About 309 A.D. it became the capital of *Gallia Narbonensis*, and had its capitol, forum, theatre, aqueducts, triumphal arches, &c. In 412 it was taken by the Visigoths, in 719 by the Saracens, from whom it was recovered by Pepin in 759, to fall just a century later to the Northmen. During the 11th and 12th centuries it was a prosperous manufacturing city, but subsequently it decayed. Varro was a native.

Narcissus, according to a Greek fable, was the son of the river god Cephissus and of the nymph Liriope or Lirioessa of Thespiæ, in Boeotia. He was a youth of extraordinary beauty, of which he was excessively vain; and for this he was punished by Nemesis by being made to fall in love with himself on seeing the reflection of his own face in a fountain. He died of this love-sickness; and on the place where he died sprang up the flower which bears his name. The story of Narcissus, narrated by Ovid, is of comparatively late origin.

Narcissus, a genus of plants of the natural order Amaryllidaceæ, having a perianth of six equal petal-like segments, and a bell-shaped corona of various magnitude. The species are natives of the south of Europe, the north of Africa, and the temperate parts of Asia. The Common Daffodil is the only one which can be regarded as truly a native of Britain. Many are cultivated in gardens for the sake of their beautiful and often fragrant flowers, which in general appear early in the season. Some of them are known by the names of Daffodil (q.v.) and Jonquil (q.v.). The name narcissus is popularly restricted to those which have flat (not rush-like) leaves, and a short (not bell-shaped) corona. Of these one of the best known is the Poet's Narcissus (*N. poeticus*), with generally one-

Narcissus poeticus.

flowered scape, the flower white and fragrant, the corona with a deeply-coloured border; others

with one or two flowers on the scape are in common cultivation. The Polyanthus *Narcissus* (*N. Tazetta*) has a number of flowers on the scape. It grows wild in stony places near the Mediterranean and eastwards to China. Many varieties of it are in cultivation. It is grown not only in gardens and greenhouses, but in water-glasses, like the hyacinth. It is very common in gardens in India, where it is highly esteemed as a flower. Narcissi are propagated by seed or by offset bulbs. They succeed best in a rich light soil, and are largely grown in the Scilly Isles.

Narcotics (Gr. *narkē*, 'stupor') are remedies which produce stupor if the dose be increased beyond a certain point. Opium is the most important member of the group, and the type from which most descriptions of the action of this class of medicines have been drawn; but it includes substances of very various properties. Some, as alcohol, produce intoxication in lesser doses; some, as belladonna, delirium; most have a primary stimulating effect: in fact, almost every one presents some peculiarity in the way in which it affects the system, and no satisfactory general description of their minor effects is possible. Their power of inducing sleep has procured for them the names of Hypnotics and Soporifics; while many of them are termed Anodynes, from their possessing the property of alleviating pain. Next to opium, Henbane, Indian Hemp, and Chloral may be regarded as the most important narcotics. Numerous artificially-produced organic compounds have been introduced, such as paraldehyde, sulphonal, trional, veronal, as hypnotics; antipyrin, exalgin, phenacetin, aspirin, as anodynes, and these have taken a permanent place among useful remedies.

Narcotics are usually administered with the view either of inducing sleep or of alleviating pain or spasm. As, however, their action is much modified by a variety of circumstances—such as age, idiosyncrasy, and prolonged use—they should be administered with extreme caution, and, as a general rule, only under competent advice. The various patent medicines for children which are known as *Carminatives*, *Soothing Syrups*, &c., are apt to contain some form of opium, and are thus responsible for part of the mortality that occurs in early life, especially among the poorer classes. All the narcotics when taken in excess are poisonous (see POISONS).

Narcotine ($C_{22}H_{23}NO_7$) is one of the organic bases or alkaloids occurring in opium, in which it usually exists in the proportion of 6 or 8 per cent. It is nearly insoluble in water, but dissolves sparingly in alcohol, readily in chloroform and ether. Narcotine possesses very slight alkaline properties. When discovered (in 1803) it was supposed to be the stimulant principle of opium; but it possesses very little activity. It yields a great variety of compounds by decomposition, one being vanillin, the flavouring principle of vanilla.

Nard. See SPIKENARD.

Nardoo (*Marsilea quadrifolia*), a plant of the order Marsileæ (see WATER-FERNS), the only plant of that order which is used in any way by man. The natives of central Australia use the spore-cases for food in bad seasons, and the explorers Burke and Wills (q.v.) attempted to sustain life on them; but they have very little nourishment, and are hard to digest. (The seeds of *Sesbania aculeata*, a plant superficially of similar growth, are much used by the Queensland natives for food, and this probably gave rise to the legend about the nourishing qualities of nardoo). Nardoo grows in places occasionally covered with water;

vegetating whilst moisture abounds, and then exhibiting abundance of green clover-like foliage,

Nardoo (*Marsilea quadrifolia*).

but becoming soft and mucilaginous when moistened. The spore-cases, pounded with their contents, are made into cakes like flour.

Nariad (or *Nadiad*), a town of Bombay province, 29 miles SE. of Ahmadabad by rail. It does a great trade in tobacco and ghi, and has a government experimental farm. Pop. (1921) 31,939.

Narragansett Bay. See RHODE ISLAND.

Narses, a statesman and general, and almost the last stay of the old Roman empire in Italy, was born in Persian Armenia about 475 A.D., and being a eunuch was probably sold as a slave in childhood. From some menial office in the imperial household at Constantinople he rose to the post of keeper of the privy-purse to the Emperor Justinian. In 538 he was sent to Italy in command of a body of troops, professedly to act in concert with Belisarius (q.v.), but in reality, it is believed, with a secret commission to observe and to control that general. After some successes Narses, having disputes with Belisarius, assumed an independent authority; but his separate command was unfortunate, and he was recalled to Constantinople in 539. After some years, however, Belisarius was recalled, and Narses was appointed to the chief command in Italy. His conduct of that expedition extorted the admiration even of his enemies. Not having the command of a sufficient number of transports, he marched his army along the whole circuit of the shore of the Adriatic, and, while the enemy's fleet were still in possession of the sea, was enabled to encounter them at Taginæ (in the Apennines), where, after a desperate engagement, the Ostrogoths were totally defeated, and their king, Totila, slain. Narses took possession of Rome, and, after a series of successes both in Southern and Northern Italy, completely extinguished the Gothic power in that peninsula. Justinian appointed Narses prefect of Italy in 554. He fixed his court at Ravenna, and continued till the death of Justinian to administer the affairs of Italy with vigour and ability. But he was charged with avarice; and his exactions pressed so heavily on the exhausted resources of the population that on the death of Justinian the Romans complained to Justin of the exactions of Narses, and that emperor deprived him in 567 of his office. He is accused of thereafter intriguing with Alboin, king of the Lombards, for a new invasion of Italy; and he died at Rome about 573. See GOTHs, JUSTINIAN; and Hodgkin's *Italy and her Invaders*.

Narthex. See BASILICA.

Narva, an Esthonian town 80 miles WSW. of Petersburg, on the Narova, 10 miles from its mouth in the Gulf of Finland. The navigation of the Narova is impeded by a waterfall near Narva, 14 feet high, which is taken advantage of for driving cotton-mills, sawmills, &c. Pop. 27,000. Charles XII. (q.v.) won a great victory here in 1700.

Narváez, RAMÓN MARIA, general and statesman, was born at Loja, in Andalusia, 5th August 1800, and when very young served in the war of liberation against the French. In 1822, when a reactionary party took up arms to destroy the work of the revolution, Narváez ranged himself on the side of the liberals. The invasion of Spain by a French army in 1823 forced him to retire from active life until the death of Ferdinand VII. in 1832. In 1834 he maintained a hot struggle against the Carlists of the Basque Provinces, and in 1836 completely routed the Carlist leader, Gómez, near Arcos. He now became immensely popular, and was regarded as the rival of Espartero. In 1838 he cleared the district of La Mancha of brigands, and was appointed in 1840 captain-general of Old Castile. He took part in the insurrection against Espartero that broke out at Seville in 1840, but, that having failed, he was compelled to flee to France, where he was shortly after joined by Queen Christina (see MARIA CHRISTINA), and commenced these plots against the government of Espartero which in 1843 effected its overthrow. In 1844 he was appointed president of council, and created Duke of Valencia. His ministry was thoroughly reactionary, but was overthrown in 1846. He was four times in power before his death, 23d April 1868.

Narvik, a port in Norway, sheltered by the Lofoden Islands and open all the year, ships iron ore brought by railway (1900) from Gellivara in Sweden; pop. 5000.

Narwhal (*Monodon*), a genus of Cetacea, belonging to the Odontocetes or toothed whales (see WHALE); it is characterised by the presence in the adult male of a long spiral tusk, and by the early disappearance of the other teeth, and by other points of less importance. The tusks may represent canine teeth, and there are sometimes a pair of them present, lying side by side in the upper jaw; there is such a specimen in the Cambridge Museum. When there is only one tusk, it is the left; rarely the female has a tusk, so rarely, however, that there are only three instances

Narwhal (*Monodon monoceros*).

on record. There is only one species known, *M. monoceros*, which inhabits the northern seas, and has been on one or two occasions stranded on British shores; it was first recorded in Britain by Vulpinus from the Isle of May in 1648; another was observed in 1800 near Boston in Lincolnshire.

It is common off the shores of Greenland, and is hunted for its oil as well as ivory; as the creature is gregarious, sometimes travelling in herds 'of many thousands,' it is captured in considerable abundance. In early times the tusk of the narwhal was valued in medicine, and to this day is so used by the Chinese. The ivory is very fine, and in the castle of Rosenborg at Copenhagen is a throne of the kings of Denmark made of this substance. The female narwhal is more spotted than the male, and the young darker. The fact that the female has not the tusk seems to negative the view that it is of use in spearing fish; it is no doubt used by the males for fighting—for examples are seldom unbroken. Fabricius thought that their use was to break and keep open holes in the ice during the winter, and observers have seen such breathing-holes crowded with heads of narwhal and other whales.

Naseby, a Northamptonshire parish, 7 miles SW. of Market-Harborough. Here, on 14th June 1645, 7500 royalists under Charles I. and Prince Rupert were totally defeated by 14,000 parliamentarians under Fairfax and Cromwell, the king losing cannon, baggage, and 5000 prisoners. A 'blockhead obelisk,' which does not mark the battlefield, was erected in 1823 on the Naseby ridge (648 feet). See Gardiner's *History of the Great Civil War* (vol ii. 1889).

Nash, JOHN, architect, born in London in 1752, after the usual course of training for his profession entered into some building speculations which enabled him to buy a small property in Carmarthen. Here in fresh speculations he lost much money; therefore, in 1792, he returned to London and architecture, in which he speedily rose to eminence. On the strength of a patent (1797) for improvements in the construction of the arches and piers of bridges, he claimed a great part of the credit of introducing the use of metal girders. A large part of his time was occupied in designing and constructing mansion-houses for the nobility and gentry in England and Ireland, but he is chiefly celebrated in connection with the great street improvements in London. From February 1815, when he was appointed 'architect, valuer, and agent to the Board of Woods and Forests,' down till near the end of his professional career, he was busily engaged in the planning of routes, grouping of buildings, and fixing of sites. He died 13th May 1835. Nash, notwithstanding his many defects, possessed great power of effective grouping, as is well shown in his works. In the architecture of mansion-houses, the designing of 'interiors' was his forte.

Nash, PAUL, artist, born in London 11th May 1889. After an art training at the Slade School he went to France in 1914, from which he returned injured in 1917. In June of that year he exhibited a collection of water-colours of 'The Ypres Salient,' which immediately attracted attention by reason of their power of drawing strange places so strangely. He was appointed one of the official artists on the Western Front, and 'Inverness Copse' and the 'Menin Road' are typical examples of his work. He has published wood-engravings in *Places* (1922), *Genesis* (1924).

Nash, RICHARD, better known as 'Beau Nash,' was born the son of an impoverished Welsh gentleman at Swansea, 18th October 1674. He was educated at Carmarthen and Jesus College, Oxford, held for some time a commission in the army, and next entered at the Middle Temple, but found greater attractions in the dissipations of society than in the pursuits of law. He conducted the pageant at the entertainment of William III. by

the Inns of Court, and is said to have declined the honour of knighthood without a pension. He made a shifty living by gambling, but in 1704 he found his true function as master of the ceremonies at Bath, where he conducted the public balls with a splendour and decency never before witnessed. In this way he came to acquire an imperial influence in the fashionable society of the place. It appears that he was also distinguished by his sentimental benevolence. He played hard and successfully; yet if he heard an individual sighing behind his chair: 'Good Heavens! how happy would that money make me,' Nash would thrust his own winnings into his hands, with theatrical generosity, and exclaim: 'Go, and be happy.' His own equipage at this period of his career was sumptuous. He used, we are told, to travel to Tunbridge in a post-chariot and six greys, with outriders, footmen, French-horns, and every other appendage of expensive parade. He is praised for the great care which he took of the morals of the young ladies who attended the Bath balls, always putting them on their guard against needy adventurers like himself. In his old age Beau Nash sank into poverty, and often felt the want of that charity which he himself had never withheld. He died at Bath, 3d February 1762. A Life by Goldsmith was published anonymously in 1762. See Gosse, *Gossip in a Library* (1891), and books by Barbeau (1904) and Melville (1907).

Nash, or NASHE, THOMAS, an entertaining writer of Elizabeth's reign, was born at Lowestoft in 1567, studied almost seven years at St John's College, Cambridge, travelled abroad, visiting Italy and Germany, and thereafter plunged recklessly into the life of letters in London, and forced a shifty living from fate until the close. He kept ever a high heart amid manifold troubles, and, satirist as he was, his inexhaustible gaiety and goodness made him the darling of his friends—the 'sweet boy' and 'sweet Tom' of Greene and Francis Meres. He was dead by 1601, as prematurely as Marlowe, Peele, and Greene. Nash had a genuine relish for good literature; he praises warmly Rabelais, Aretino, Spenser, Sidney, and Marlowe. He had also a great faculty for vituperation, and the times were favourable for its exercise. His first writing was his vigorous preface to Greene's *Menaphon* (1589), and this was quickly followed by the *Anatomie of Absurditie* (1589), a satirical discussion on social manners; a series of impetuous tractates flung into the Marprelate controversy; *Pierce Penilesse, his Supplication to the Divell* (1592), full of keen observation and satire, and rich in autobiographical interest; *Strange News* (1593); and *Have with you to Saffron Walden* (1596), containing a vehement onslaught on Gabriel Harvey; *The Terrors of the Night, or a Discourse of Apparitions* (1594); *Christ's Tears over Jerusalem* (1593), a long, edifying discourse; *The Unfortunate Traveller, or the Life of Jack Wilton* (1594), the best specimen of the picaresque tale in our literature before Defoe; *The Isle of Dogs* (1597), which was at once suppressed, and is now lost, and for which the author was sent to prison; and *Lenten Stuffe* (1599), 'in praise of the red herring,' really a humorous description of Yarmouth. The tragedy of *Dido* was written in collaboration with Marlowe; *Summer's Last Will and Testament*, by Nash alone.

There are editions of his works by Grosart (1884) and McKerrow (1904-5). See Gosse's edition of *The Unfortunate Traveller* (1892), Brett-Smith's (1920), Jusserand's *The English Novel in the Time of Shakespeare* (trans. 1890).

Nashua, a manufacturing city of New Hampshire, is 40 miles by rail NW. of Boston, at the

junction of the Merrimac and Nashua rivers. The falls of the latter, rendered available by a canal 3 miles long, supply motive-power to many manufacturing establishments, including very extensive cotton-factories and ironworks, paper-mills, &c. Pop. (1880) 13,397; (1920) 28,379.

Nashville, the capital of Tennessee, is on the navigable Cumberland River, 200 miles above the Ohio, and 185 miles by rail SSW. of Louisville. The city, which is one of the principal railway centres in the southern states, is built mainly on the left bank of the river, which is crossed by a suspension bridge and a railway drawbridge to the suburb of Edgefield. Nashville is a handsome, well-built town, with an imposing state capitol of limestone, a penitentiary, and a large lunatic asylum. As an educational centre the city is of considerable importance. The public-school system is excellent; and here are the Vanderbilt University (1875), Fisk University (Congregationalist, 1867, with few but coloured students), the state normal college, &c. The city has a large wholesale trade, the staples being lumber, cotton, and tobacco; while its manufactures, which are rapidly extending, include cotton, flour, timber, iron, and phosphates. Founded in 1780, Nashville became the legal capital in 1843. In December 1864 the Confederates under Hood were completely defeated here by Thomas. Pop. (1880) 43,350; (1890) 76,169; (1920) 118,342.

Nasik, a town of Bombay, on the Godavari, 31 miles from its source, with a railway station (4 miles distant), 100 miles NE. of Bombay. It ranks as one of the most sacred of Hindu places of pilgrimage, the banks and even the bed of the river being crowded with temples and shrines. Formerly it was a Mahratta capital; now it manufactures paper, cotton, and excellent brass and copper work. Pop. (1921) 42,756. See **MAGIC SQUARES**.

Nasmyth, JAMES, inventor of the steam-hammer, was the son of Alexander Nasmyth (1758-1840), portrait and landscape painter, best known by his portrait of Burns. He was born in Edinburgh, 19th August 1808. From boyhood he evinced a turn for mechanics, and in his father's house became accustomed to use a lathe. At seventeen he constructed a small working steam-engine for grinding his father's colours, and made besides five models of a condensing steam-engine, and later a small road locomotive. Employed in 1829 by Maudsley, he started in business at Manchester in 1834, gained a good connection, and established at Patricroft what afterwards became known as the Bridgewater Foundry. The invention of the Steam-hammer (q.v.) was conceived in 1839, the occasion being the necessity for forging an enormous wrought-iron paddle shaft. But it did not take shape till 1842, when he found the steam-hammer as he had planned it at work at Creuzot in France. It had been adapted from his own scheme-book. Nasmyth patented his invention on his return to England, and it was adopted by the Admiralty in 1843. Business increased, and by 1856 he was able to retire with a handsome fortune, and settled at Penshurst, Kent. Amongst his other inventions was a steam pile-driver. He published *Remarks on Tools and Machinery* (1858), and a volume on *the Moon* (1874). He died in London, 7th May 1890. See *Autobiography*, edited by Smiles (1883).

Naso. See **OVID**.

Nassau, formerly a German duchy, now the Wiesbaden district of the Prussian province of Hesse-Nassau (q.v.). The soil is fertile, and produces some of the most esteemed Rhenish wines. The chief towns are Wiesbaden (q.v.), the capital of the district; Schwalbach, Schlagenbad, Fachingen, Selters, and Geilnau.—The family of

Nassau, the elder branch of which reigned till 1866, dates from the 10th century. The younger branch inherited in 1544 the principality of Orange (q.v.), and as the princes of Orange took an important place in European history (see **HOLLAND**). The reigning Duke of Nassau sided against Prussia in 1866, and his duchy was incorporated with Prussia (see **PRUSSIA, GERMANY**); and on the extinction of the male line of the Orange branch by the death of William III. of Holland, in 1890, the Duke of Nassau became Grand-duke of Luxemburg.

Nassau, in New Providence, capital and trading centre of the Bahamas (q.v.) and a bishop's see; pop. 13,000.

Nasturtium, properly the botanical name of the Water Cress (see **CRESS**), but also the popular designation of the Indian Cress (*Tropaeolum majus*). See **TROPEOLUM**.

Natal, an original province of the Union of South Africa, was discovered by Vasco da Gama on the Christmas-day (hence its name) of 1497. In the 18th century intermittent trading was carried on between the Cape Colony and Natal, which in 1800 was peopled by ninety-four distinct tribes of natives. From 1805 to 1828 the despotic Zulu chief Tyaka (Chaka) enforced his own rule and that of his own immediate tribe or family clan, the Amazulu, over the congeries of tribes reaching from the Limpopo on the north to the Kei River in the south. Tyaka was killed in 1828 by a political faction who placed his younger brother Dingaan on the throne. Predatory Boers who had left the Cape Colony to escape British rule divided into parties and settled in the territories now known as Natal and the Transvaal; and conflicts between Boers and natives were very frequent. In 1838 an embassy of Boers were massacred by Dingaan, and a force of Boers proceeded to Zululand to avenge their friends. The country was at this time divided into two factions, one supporting Dingaan, and the other his younger brother Umpande (Panda). The Boers entered into a secret treaty with the latter, and a combined attack was made on Dingaan, who fled and was killed. Panda succeeded him as king, and the Boers were recognised as lords of the soil of Natal. In December 1838 Sir George Napier, the Cape governor, had sent a detachment of Highland troops to take possession of the inland territory and Port Natal; but owing to the Cape Kaffir disturbances the Highlanders were withdrawn, and the Boers at once hoisted the flag of 'the Republic of Natalia.' Two British ships of war were sent from the Cape to force a landing at Durban. After a short struggle there the Boers gave up the port, and fell back on Pietermaritzburg, the capital, the name of which is a compound of the Christian name of Pieter Retief and the surname of Gert Maritz, two leaders of the Boers. Civil negotiations were then entered on by Mr Cloete, and many of the Boers accepted British rule and settled down in Natal. Those of the malcontents who crossed the Drakensberg and struck north soon found themselves fighting against Umzilikatzé (father of Lobengula of Matabeleland) in the territory now known as the Transvaal. In 1843 Natal was officially declared to be a part of the British dominions, and the colony was formally annexed to the Cape of Good Hope on the 31st of May 1844. At that time the natives numbered about 150,000, although in the previous century their total was nearly a million. But intertribal fights and the struggles for supremacy of Tyaka scattered the clans of Natal far and wide. Subsequent to the annexation by the crown and its attendant peace the aborigines of Natal gradually returned from distant places, and their numbers, still below half

a million in 1891, are now nearly a million. In 1855 there was a great flood in the colony and Zululand, and in the following year a very sanguinary fight for the Zulu succession took place on the Natal northern border between two sons of Umpande—viz. Cetewayo and Umbulaze. After a bloody battle on the Tugela River the forces of the former won the day, and Umbulaze's beaten men took refuge in Natal. On the 15th of July 1856 Natal was declared to be a separate British colony, and it was then given a limited form of representative institutions. During the decade ending with 1860 considerable immigration from Great Britain took place, and the immigrants of that time and their descendants occupy most of the land of the province to-day.

In 1873 friction arose between Langalibalele, one of the chiefs on the north-west boundary, and the next magistrate. Some of the chief's young men disobeyed the mandate of the magistrate to give up their guns. Orders were issued to apprehend the chief and certain of his followers. They retreated before the crown forces, but some of the Natal volunteers and mounted police cut them off in one of the mountain-passes; bloodshed ensued, and three well-known young colonists were killed. Langalibalele escaped to Basutoland, but was captured and brought back, tried very summarily in Maritzburg, and banished to the Cape Colony. Rigorous measures were adopted by the governor against Langalibalele's tribe and a neighbouring tribe. The home government, however, interfered, and ended the injustice which had been done to the natives by the colonial authorities while under a feeling of panic. Langalibalele remained in the Cape Colony till 1885, when he was allowed to return to Natal as a prisoner on parole; he died near Maritzburg in 1889.

In 1875, there being in the colony much dissatisfaction with the methods of Downing Street rule, Sir Garnet Wolseley was sent out to settle matters. He promulgated a new constitution providing for an extension of the representative system, with the check of certain eminent colonists, selected by the crown, having seats in the Legislative Council as nominee members. Sir Garnet Wolseley was succeeded by Sir Henry Bulwer. During the governorship of the latter a feeling of disquiet was shown in some quarters at the strength of the colony's neighbours, the Zulus under Cetewayo. Sir Bartle Frere, Her Majesty's High Commissioner for South Africa, visited the colony, and came to the conclusion that in the interests of the British colonists in South Africa it was necessary to break the power of the Zulus. Despite the protests of the Natal government and Sir Henry Bulwer, the governor, an ultimatum was served on the Zulu king, and war ensued (see ZULUS). In this war Natal suffered severely in the lives of its young colonists, in its treasure, and in the paralysis of its trade. For several years the colony was a camping-ground for British troops, for in 1881 the Transvaal Boers invaded Natal to anticipate the advance of English soldiers being sent to support those beleaguered in the Transvaal garrisons; and the fights of Schuin's Hoogte, Ingogo, Laing's Nek, and Amajuba (see MAJUBA) were all fought on British soil. The province of Zululand was annexed to Natal in 1897. On the outbreak of the South African war in October 1899, the northern part of Natal was overrun by a large force of Boers, who did great damage to railways and private property. After severe fighting at Dundee, Elandslaagte, and Nicholson's Nek, the British forces were shut up in Ladysmith, which was besieged from 2nd November till 28th February 1900, when it was relieved by General Sir Redvers Buller after much hard fighting at the river Tugela, Colenso, Spion Kop, and Vaal

Krantz. The Boers were finally driven out of Natal on 11th June 1900. After the war, the Transvaal districts of Vryheid, Utrecht, and Wakkerstroom were added to the territory of Natal in January 1903 (see TRANSVAAL).

A native rising in 1906 was put down by the Natal forces under Sir Duncan M'Kenzie. At this time the home government's action in postponing the execution of natives convicted of murder was hotly resented in Natal. In 1910, notwithstanding strong particularism, Natal became an original province of the Union of South Africa.

Natal covers an area of 35,291 sq. m., including 6970 sq. m. added in 1903. Towards the coast the Drakensberg Mountains present a scarped and almost inaccessible face, but gradually die away into the immense rolling plains of the interior.

The coast region, extending for 30 miles inland, is highly fertile, the climate being subtropical and healthy. In 1856 the cultivation of the sugar-cane was introduced on the coast, and as an industry it has thriven more or less ever since. In 1903 the area under sugar was over 33,000 acres, and the total produce was 34,000 tons; in 1911 it was 80,000 tons; in 1923, 159,000 tons. The culture of the cane requiring that continuous and arduous labour which the natives did not supply, the Legislative Council had, in 1863, to take steps to introduce immigrants from British India; and in 1904 there were in the colony over 100,000 Asiatics—coolies, with their attendant traders who followed them from India. By 1911 the number was over 133,000, many being shopkeepers and market-gardeners freed from their indentures. Their presence has been strongly objected to. The Assam tea-plant was introduced in 1877, and tea-planting has become a staple industry. The black wattle (*Acacia mollissima*) is very extensively grown for the sake of its bark, which is used for tanning. Coffee, maize, tobacco, oats, and vegetables are also important crops; and indigo, arrowroot, and ginger have been grown. All tropical fruits thrive well. The midland terrace is more fit for the cereals and usual European crops; while on the higher plateaus along the foot of the mountains are immense tracts of the finest pasturage for cattle and sheep.

The climate is very healthy; the thermometer ranges between 90° and 38° F., but the heat even in summer is seldom oppressive. The mean annual temperature at Pietermaritzburg, the capital, is 64·71°. The winter begins in April and ends in September. In the summer season the thunderstorms are very frequent and severe in the uplands. The annual rainfall over the whole province averages nearly 40 inches, the greatest fall being in summer.

The province has only one harbour worthy of the name, but that is the best on the south-east coast, Durban (q.v.) or Port Natal. The harbour is of great consequence not only to the province, but to the empire, as it must one day be an important fuelling station. The principal rivers are the Tugela, Buffalo, Umkomanzi, Umgeni, Umzimkulu, and Mooli. Like the majority of African rivers, they are of little use for purposes of inland navigation; but their streams are permanent, and often available for irrigating purposes.

Coal is destined to play a prominent part in the future of Natal, the area of the coal-measures being estimated at 1400 sq. m. The coal is serviceable for all ordinary purposes, the Union government railways being worked with it. Copper has been found, and much is hoped from the iron near the coal. The colony is also believed to be rich in other minerals, such as asbestos, mica, and plumbago. Gold has been found in the south and north. Great forests of fine timber abound in the mountain-passes, while many tracts along the coast

are well wooded. The chief towns are Pietermaritzburg (35,000), 54 miles inland, the seat of colonial, and now provincial, government and the chief military station; Durban, the greatest town; Verulam and Pine Town near the coast, Harding in the south, and Richmond, Weenen, Colenso, Greytown, Ladysmith, Estcourt, Dundee, Utrecht, Vryheid, and Newcastle up country.

The colonists were offered responsible government in 1883, with guarantees for native protection, but they refused the offer; and the bill providing responsible government passed the Council only by a narrow majority in 1891. From 1893 to 1910 the government was administered by a governor, assisted by a ministry, a Legislative Council of thirteen members, and a Legislative Assembly of forty-three members. The governor appointed ministers, and with their advice the Legislative Council. The Assembly was, of course, elective. The parliament lasted for four years, unless dissolved before then. Natal became a province of the Union of South Africa in 1910. It has an administrator and a provincial council of twenty-five members. About 1865 Natal was plunged into ecclesiastical warfare. Bishop Colenso (q.v.), the then head of the diocese, was declared heterodox by a party in the church, and unsuccessful efforts were made in South Africa and England to depose him. The Presbyterian (Scottish and Dutch), Roman Catholic, and other churches are well represented; many stations of the Wesleyan, American, Norwegian, and other missions exist; and the Trappists (q.v.) do good work near Pine Town. Education is well provided for. Natal University College at Pietermaritzburg was incorporated in 1909, and in 1918 became a constituent college of the university of South Africa. In addition to the government-aided high schools, primary schools, and art schools, there are schools for natives and for the children of Indians, all receiving government grants.

The chief passes through the Drakensberg are Van Reenen's, Oliver's Hoek, Bezuidenhout, De Beer's, and Laing's Nek. Most of the rivers have been substantially bridged, and a very energetic policy of public works is being pursued by the government. Several railways run through the province, and connect the coast with the Orange Free State and Transvaal. Lines are also laid north and south of Durban along the coast.

Natal's chief exports are bullion, wool, sugar, tea, coal, maize, and wattle-bark. The chief imports are apparel and haberdashery, railway material, provisions, flour and grain, ironmongery, cottons, woollens, beer and spirits, leather and leather goods. In 1876 the population numbered 326,957 (20,490 whites); in 1911, 1,191,958 (98,582 whites, 951,808 natives, and 141,568 others); in 1921, 1,571,047 (136,833 whites, 1,292,560 natives, 141,649 Asiatics). The natives possess horses, cattle, sheep, &c. They are a fine race physically, gifted with high intelligence, of frank and courteous bearing, and very easy to govern.

The common law in the province is that prevailing in Holland during the 16th and 17th centuries, modified by statute law in the same way practically as obtains in all parts of South Africa. The chief difference between English and Roman Dutch law rests in the laws of marriage and inheritance, but the difference is now by statute largely optional. The coolies are subject to the laws regulating Europeans, as well as to special laws controlling Indian immigration. The natives are, with few civilised and exempted exceptions, subject in civil matters to native law, which is quite different from colonial law. The Natal Provincial Division of the Supreme Court of South Africa consists of the judge-president and three puisne justices, the

Native High Court of a judge-president and two judges; and there are stipendiary magistrates in all important centres.

Eland (q.v.) and hartebeest (see ANTELOPE) are the only big game left, and these have been made royal game. There are stringent laws for the protection of deer and game-birds. Alligators are met with in a few of the central and northern rivers. Snakes, both colubrine and viperine, are plentifully distributed throughout the province. Many of the snakes are innocuous, and fatal bites from the poisonous species are rare. The python, which attains a large size, is to be found in the seacoast forests, and in the reeds by the river-sides. The hippopotamus is still to be met with at the mouths of some of the northern rivers.

See John Bird, *The Annals of Natal* (1889); *Natal Almanac*; John Noble, *South Africa, Past and Present* (1877); Sir John Robinson, *Notes on Natal and A Lifetime in South Africa* (1900); Brooks, *Natal* (1869); Russell, *The Garden Colony* (1903); Justice Cadiz, *Laws and Ordinances of Natal*; W. Y. Campbell, *Code of Native Law, Civil and Penal*.

Natal, a seaport of Brazil, capital of the province of Rio Grande do Norte, stands at the mouth of the river of that name. It exports principally cotton and sugar. Pop. 30,000.

Natal Cotton. See SWEET POTATO.

Natchez, capital of Adams county, Mississippi, is on the east bank of the Mississippi River, 214 miles by rail and about 280 by water NNW. of New Orleans. It is built mainly on a high bluff, looking out far over the cypress swamps of Louisiana; the part of the city along the bank, where the heavy shipping business (mainly in cotton) is transacted, is known as Natchez-under-the-Hill. The public buildings include a Roman Catholic cathedral and a United States marine hospital. Natchez, which was settled by the French in 1716, derives its name from a former tribe of Indians (see MOUND BUILDERS). Pop. (1870) 9057; (1880) 7058; (1900) 12,210; (1920) 12,608.

National Convention (1792-95). See FRANCE, GIRONDISTS, JACOBINS, ROBESPIERRE.

National Covenant. See COVENANT.

National Debt. National or public debts, although of early origin, were relatively of small importance before the development of the modern system of banking and credit, and it is only since the 19th century that they have become almost universal on a considerable scale (see Gilbart on *Banking*, sect. i.). So long as it was necessary either to give pledges such as crown jewels or to assign specified revenues, it was not possible that public debts could attain any great magnitude. As soon, however, as governments were able to borrow simply on credit, national debts in the modern sense of the term grew rapidly. In less than a century after the foundation of the Bank of England (1694), when for the first time in English history the item 'Interest and Management of the Public Debt' appears in the national accounts, Adam Smith felt compelled to enter a protest against 'the progress of the enormous debts which at present (1776) oppress, and will in the long-run probably ruin, all the great nations of Europe.' At that time the public debts of the civilised world were, however, only about one-tenth of their amount in 1900, which exceeded five thousand million pounds sterling, exclusive of local obligations. Although the English national debt received a great augmentation during the great Napoleonic wars, the general indebtedness of civilised nations has increased most rapidly since 1848. In fact, from that year it has been calculated that there was an annual average deficit in the public accounts of the world of over

£100,000,000. In 1862 there were quoted on the London Stock Exchange foreign public stocks to the amount of nearly £700,000,000, whilst ten years later these quotations had increased to nearly £2,500,000,000. In 1890 there were more than one hundred and fifty public securities dealt in the London market (see Adams on *Public Debts*, part i. chap. i.). Seeing, then, that national debts are now practically universal in the civilised world, and that the amounts and conditions under which they are held are constantly changing, a purely historical or statistical account is plainly out of the question in the limits of the present article. It will only be possible to indicate the most general characteristics and principles involved, and also some of the leading points of controversy. As regards *origin*, undoubtedly the most important cause of public indebtedness is, and always has been, war-expenditure. Thus the Napoleonic wars increased the English debt by over £600,000,000, the United States civil war cost the victors £450,000,000, and the Franco-German war added £390,000,000 to the total of national indebtedness. The vast accumulations due to the European war can be seen from the tables appended.

In modern times, however, governments have added largely to their indebtedness by borrowing for various public purposes of an industrial or social character. In France especially, in spite of great changes of government, expenditure of this kind has gone on increasing at an alarming rate; the amount of taxation per head of population has increased by seventy per cent., and this is largely due to the growth of administrative functions on the part of the state. In the British colonies also the rapid increase of public indebtedness must be ascribed principally to the same cause. The progress of civilisation necessarily imposes, as Adam Smith, Mill, and other economists have pointed out, new industrial functions upon governments, and it is impossible that these can in all cases be fulfilled in a directly remunerative manner. But, apart from this natural growth, in recent years a quasi-socialistic tendency has become pronounced, which has involved a large increase in public expenditure. The full importance, however, of this element can only be seen when account is taken of local taxation and indebtedness, which would require a separate investigation. It must also be observed that money spent on debts incurred for public purposes may in some cases—e.g. railways, docks, &c., be directly profitable, and in others—e.g. education, be indirectly remunerative.

The nature of public debts differs in some respects from that of private obligations. It is held, for example, that the government of a sovereign state has the discretionary power of enforcing the claims of its subjects for payment of the national (as contrasted with domestic) obligations of another state. The interests of bondholders may in consequence give rise to diplomatic intervention and thus lead to political disturbances, as has been shown by the action of England and France in Egypt and Tunis respectively. The growth of national indebtedness has, however, hitherto been generally accompanied by an increased sense of responsibility founded on the importance of public credit, and fundamental revolutions in government have not generally given rise to repudiation, although the new government might strongly disapprove of the objects for which the debt was incurred, or the methods by which the money was raised—compare, for example, the history of France during the 19th century and the revolution in Brazil in 1889. On several occasions, however, specious arguments for partial repudiation have been urged and met with some popular countenance.

It has been maintained that if a debt has been

incurred in a depreciated currency—that is to say, if the government has only received the capital sum borrowed in this form—it is only equitably bound to pay back the principal with an allowance for its depreciation. This position was taken up by some writers as regards the English debt incurred during the period of the bank restriction, when Bank of England notes were inconvertible and depreciated, and then later the same reasoning was advanced in the United States after the civil war. The obvious answer, however, is that a government would receive so much less capital if the lenders were not assured against uncertain depreciation. The amount actually received for a nominal capital sum will clearly vary, according to the standard in which the payment is to be ultimately met (see Mill's *Political Economy*, bk. iii. chap. xiii.). In the same way it has sometimes been maintained that if a government has borrowed at a discount, and its stock has afterwards risen to par, the fundholders have no equitable right to this rise in value caused by the growth of credit and national prosperity. But again the reply is that the chance of their rise in the future was taken into account by those who made the original advances, and that they would have required so much more interest if they were to be entitled simply to a return of the original sum actually advanced. The practical conclusion to be drawn from this argument is that in general it is bad policy for a nation to borrow at a discount, because it is deprived of the opportunity of conversion to a lower rate of interest. Suppose, for example, that a nation can only borrow at par at six per cent., it is better to do this than to borrow nominally at three per cent., and create (roughly) double the amount of capital obligation for the same sum actually received. In the former case every fall in the rate of interest at which the nation can borrow may be taken advantage of by a process of conversion, whilst in the latter case the whole gain accrues to the fundholders. It is of course assumed that the debt may be paid off at any time (or with a short notice), and that payment is not definitely fixed for certain dates. The opposite case of the United States shows the importance of this provision.

It is, however, true as before that the certainty of high interest for a fixed period will operate upon the amount actually given for every nominal hundred, but the point is that the state is better fitted to take advantage of the probable ultimate fall in the rate of interest. A somewhat similar argument has been advanced by Dr Chalmers and others to show that, considering the nature of a state, it is better always to meet current expenses, however extraordinary, out of present taxation, rather than to resort to loans. The contention is that to meet the actual expenditure the government must in some form or other actually take the required amount from the sum total of the national wealth. If it makes a loan it is said that it really takes the capital amount and diverts it from productive purposes, just as effectively as if it obtained the money directly by taxation, but in addition is burdened in perpetuity with the interest. The circumstances under which the national debt of England was so largely increased in the Napoleonic wars no doubt seemed to justify this position. According to a Parliamentary Return of 1869 it was shown that from 1793–1816 the total income raised from taxes amounted to 1149 millions, and the total expenditure, except for the interest on the debt, amounted to 1103 millions. That is to say, for the twenty-three years (apart from the interest on the debt) the whole civil, military, and naval expenditure was less than the amount received in taxes by 46 millions. Now the charge

on the original debt before the war was about 9½ millions per annum, or for the twenty-three years about 220 millions. Against this must be set the 46 millions of surplus shown above, leaving on the net deficit for the twenty-three years about 174 millions. But to meet this sum the national debt was by a process of borrowing and repayment actually increased by some £622 millions (see Noble's *National Finance*, p. 3, note). In answer to the general argument, however, it may be pointed out that the borrowing may be made not from the productive resources of a country, but from foreign capital or the general accumulations of the world, or that the loan may absorb wealth which otherwise would not have been saved at all, or may intercept wealth which might otherwise have gone abroad. Mill argues (*Political Economy*, bk. v. chap. vii. sect. i.) that a sufficient test whether the loan is really made from productive capital is given by the effect on the rate of interest. If the rate rises the presumption is that the productive capital has been really drawn upon. This test, however, can only be used with caution, if at all, for the rate of interest depends upon many factors—e.g. the state of credit, the general economic conditions of other nations, &c.; and on the anticipation of the outbreak of war a rise is certain to take place independently of the action upon the productive capital of the country.

The question next arises: Supposing a national debt in existence, should any effort be made to extinguish the principal? The chief arguments against any special exertion towards repayment are the following: (1) It is said that the payment of the interest constitutes a mere transfer of wealth from one class of the community to another, and therefore is no real burden. But in reply it may be urged that all taxation necessarily implies loss both directly and indirectly, the indirect and 'unseen' loss being much greater. Thus in the United Kingdom, whilst the direct expense of the customs duties has been placed at only 3½ per cent., the indirect loss has been calculated by Cliffe Leslie and others at from 20 to 30 per cent. In some cases also the national creditors are foreigners, and in this case the payment of interest must take the form of a real exportation of wealth without any corresponding importation. (2) It is argued that with the natural progress of society industrial countries become more and more wealthy, that the burden of the debt becomes proportionately less, and that its extinction can be more easily effected at a more remote period. It ought to be observed, however, that the rapid accumulations in recent times have been largely due to exceptional and great changes in connection with machinery, railways, telegraphs, financial reform, foreign trade, education, &c., and that, although the same causes will remain in operation, the rate of increase may not be so great. In certain countries also, notably France, population is almost stationary, and in nearly all the marriage rate is declining. (3) It is said that the rate of interest tends to fall, and that therefore by conversion the real burden may become less and less. The experience of Britain and of the United States in the late 19th century supported this view; but, on the other hand, there are various elements of uncertainty—e.g. the opening up of new countries, the possibility of great wars, &c. (4) It is maintained that the existence of a national debt, which consists practically of perpetual annuities guaranteed by the state, is a national convenience; and, further, that if the debt were extinguished capital would tend to be sent abroad. The answer is that under modern conditions there are many safe investments, and that only surplus capital migrates from a country. (5) It is said that it is unjust to the present generation

to impose a burden upon it simply for the benefit of future and probably more wealthy generations; but it may be rejoined that we must consider the continuity of national life, and remember that the present race is supposed to enjoy the benefits of former sacrifices.

On a balance of arguments most economists have approved of the rule that it is advisable to pay off debt, so long as the taxes by which the surplus is raised do not directly or indirectly impose still greater burdens. A bad system of customs and excise duties, for example, by checking the natural development of production and trade, may practically leave the nation poorer than if it had not paid off its debt by such means. On the other hand, if remissions of taxation have already been carried so far as to leave the burden of taxation comparatively light, it is better to use any surplus rather for the payment of debt than for a further reduction of taxation. In support of this view, it may be added that the less the previous debt, so much the greater would the power of a state be in making a loan in case of exceptional need. A nation already overburdened with debt might be obliged, in the case of a great war, immediately to resort to a forced currency, which would be liable to a serious or fluctuating depreciation. An issue of inconvertible notes is generally the worst method of incurring a national obligation, being in reality a species of forced loan. At one time a favourite argument against the immediate repayment of public debts was the assertion that there was in progress a natural depreciation of gold, owing to great discoveries and to the use of credit substitutes. This argument must, however, now be reversed, for the debts of the Great War have been contracted in an inflated currency, and this, as a process of deflation sets in, will make the real burden of this debt so much heavier. With falling prices and falling incomes, the same amount of nominal taxation involves greater sacrifices on the part of the taxpayers. Accordingly it will be advisable to reduce money debts of all kinds as rapidly as possible. It should also be noticed that 'an old tax is no tax,' and that in general it is not advisable to lessen or abolish taxes which must afterwards be reimposed. It is preferable to create a surplus for the extinction of debt. The case of the United States with a surplus larger than could be made use of, and raised to a great extent by burdensome indirect taxation, may be regarded rather as an exception which proves the rule.

In conclusion, attention may be called to the principal methods adopted for the extinction of public debts. These are mainly two, with variations in detail. First, there is the simple plan of raising directly more in revenue than is required for expenditure, and devoting the surplus directly to the purchase of the bonds or stock representing the debt. A continuous surplus of this kind is a real sinking fund. In former times many fallacies have been current regarding the powers of a sinking fund. Financiers have been deluded through spurious figures on the powers of indefinite accumulation of a small sum at compound interest, and have imagined that if a certain sum were set aside and allowed to grow in this manner, it would insensibly extinguish any debt. If, however, in the meantime, the state, as in the case of England during the Napoleonic wars, continues to borrow at higher rates, a sinking fund of this kind is directly worse than useless, although indirectly it may find defenders on the ground that a suspension would injure the national credit. The second method of repayment which has met with much favour in the United Kingdom is the substitution of terminable annuities, at a higher rate, for the perpetual annuities which constitute

the interest on the debt. The great advantage of this plan is that there is so far no apparent surplus which the government or the people can devote to a reduction of taxes or to new modes of expenditure, whilst a sinking fund is always open to attack. If the stock has originally been issued at a discount, and a rise may be expected, the adoption of terminable annuities gives the nation the benefit of this rise, whilst the gradual diminution of the debt of itself increases the tendency to rise.

A third method of getting rid of public debts has sometimes been proposed, founded upon the fact that a state can borrow on lower terms, or that its credit is better, than is the case of private individuals or companies. Thus it was argued that the state might purchase the railways, the ordinary stock of which in the United Kingdom earned, before the war, about 4 per cent., with money borrowed at less than 3 per cent. Adam Smith, however, long ago pointed out that a nation can rarely make a profit of any industrial undertaking, and to judge by recent experience that criticism still holds good.

Another proposed method which has come into prominence since the war is that of a levy on capital.

In 1750-57 took place the first great consolidation of stocks (see CONSOLS); in 1888 the '3 per cents.' were consolidated into 'new stock' to bear 2½ per cent. till 1903, and thereafter 2½ (see also EXCHEQUER BILLS).

DEBT OF UNITED KINGDOM AT VARIOUS DATES.

At the Revolution of 1688	£664,263
At the accession of Queen Anne	12,767,225
At the accession of George I.	86,175,460
At the end of the Spanish war, 1748	75,812,132

National Gallery, the principal depository of the pictures belonging to the British nation. The present building, which was intended to accommodate the Royal Academy and National Gallery, stands in Trafalgar Square, London, and was finished in 1838 at a cost of £100,000, but was enlarged in 1861, in 1869, in 1876, and in 1887. The nucleus of the National Gallery was the Angerstein collection of thirty-eight pictures, purchased in 1824 for £57,000, and a considerable sum is now annually voted by parliament for the purpose of adding to it. The various early and late Italian schools are extensively illustrated; there are good examples of the chief representatives of Italian art, as Raphael, Correggio, Paul Veronese. There are a few good examples of Murillo and Velázquez and the Spanish school; and the great Dutch and Flemish painters, Rembrandt, Rubens, Van Dyck, and the others, are well represented. The Royal Academy of Arts, which used to have its headquarters here, is now established at Burlington House. See also WAL-LACE (SIR RICHARD).

The NATIONAL PORTRAIT GALLERY, founded in 1856, was established at South Kensington in 1869, but removed on loan to the Bethnal Green Museum in 1885. Thence it was finally transferred in 1896, to occupy a handsome suite of buildings erected for it at the rear of the National Gallery.

There are also National Galleries of Art in Edinburgh and Dublin; the great public collections of Paris, Berlin, Dresden, Munich, Florence, Rome, &c. are mentioned in the articles on those cities.

National Guard, an organisation for local defence, at the disposal of the municipalities, not of the crown. Such a burgher guard had long existed in many French towns, but it was introduced into Paris only in July 1789, during the Revolution, when the revolutionary leaders decreed the formation of a national guard for Paris of 48,000 citizens; and ere long there were 300,000 for the kingdom. During the revolutionary excesses they were sometimes supine, sometimes they withstood the more violent insurrectionists. In 1794 they were the most devoted adherents of Robespierre. In 1795 they assisted in disarming the people, and were themselves reorganised so as to exclude turbulent elements, none but men of substance being allowed to serve; they even became royalist in feeling, and, rebelling against the convention, were defeated by Napoleon and the regular army, and practically ceased to exist. Napoleon re-established a national guard or militia, but, after various vicissitudes in 1814, 1830, and 1845, it has been wholly superseded by the military reorganisation since 1870.

National Hymns. The origin of the English national anthem has been a subject of controversy since the end of the 18th century, and is still involved in obscurity. 'God save the King' was first printed in the *Harmonia Anglicana* of 1742, without name of author or composer, varying slightly from the present version; and in 1745, during the Scottish rebellion, it became widely known, ver-

sions of it being sung nightly at Drury Lane and Covent Garden Theatres with great applause. Of the numerous claims to its parentage, the view supported by most, and by several eminent writers, attributes it, both words and music, to Henry Carey (q.v.), the popular song-writer, about 1740. The evidence for this is given in Chappell's *Popular Music of the Olden Time*, and Chrysander's *Jahrbücher*, vol. i. But Mr W. H. Cummings, who thoroughly beat out the subject in a series of papers in the *Musical Times* in 1878, entitled to the greatest weight, considers this evidence untrustworthy; and he arrives at the conclusion that the music has been adopted (but when, and by whom, we shall probably never know) from an 'Ayre' by Dr John Bull (q.v.), found (without words) in a collection of music by him once in the hands of Dr Kitchener, afterwards of Richard Clark, the original of which seems to have disappeared. It is also attributed by some to James Oswald.

The hymn was translated into German by Heinrich Harries, a Holstein clergyman, and sung to the original air at a birthday celebration in honour of the king of Denmark in 1790; and an adaptation from these words, made in 1793 by Dr B. G. Schumacher, beginning 'Heil dir im Siegerkrantz,' came into use as the Prussian national hymn. It called forth the admiration of Beethoven and Haydn, and moved the latter to compose an Austrian national hymn, which was first sung on the Emperor Franz's birthday in 1797. The best-known words, beginning, 'Gott erhalte Franz den Kaiser,' are by Baron Zedlitz; the original words were by Haschka. 'Deutschland, Deutschland über alles' is sung to the same tune. The first chancellor of the Austrian republic, Dr Renner, composed a new national hymn, 'Deutsch-Oesterreich, du herrliches Land.' The Hungarians have two national hymns—the 'Szózat' ('The Appeal'), beginning, 'Be true to the land of thy birth,' written by Vörösmarty (1800–55), the creator of Hungarian poetry of the Romantic school, and composed by Benjamin Egressy, an actor and eminent composer of sacred music; and the 'Magyar Hymnusz,' written by Kölcsey and composed by Francis Erkel. The Rákóczy march, by an unknown composer, dates from the end of the 17th century. The Russian anthem, dating from 1830, the work of General Alexis Lwoff (1799–1870), was set aside at the Revolution, and international songs ('The Red Flag' and 'The Internationale') took the place of national. Of the Danish national hymn, 'Kong Christian,' the words are by Ewald and the music by Johann Ernst Hartmann (1726–91). There are several claimants to the honour of being the Norwegian national hymn, of which may be mentioned 'Sønner af Norge,' written about the beginning of the 19th century, music by C. Blom; and the modern 'Ja, vi elsker dette Landet' ('Yes, we love this land'), words by Björnson, music by R. Nordraak. The Swedish hymn, 'King Karl, the young hero,' was written by Esaias Tegner (1782–1846). The Dutch national hymn, 'Wien Neerlandsch Bloed,' was written by Henrik Tollens (1780–1856), and composed by J. W. Wilms. 'La Brabançonne,' the Belgian revolutionary song of 1830, was written by Jenneval, a Brussels actor, and composed by Campenhout. The 'Marseillaise' is the subject of a separate article. The officially recognised national hymn of Italy is rather a march ('Inno reale'), composed, without words, by Giuseppe Gabetti (1796–1862), and seldom sung. The music to the patriotic hymn of Mamei ('Fratelli d'Italia') was composed by Michele Novaro (1822–85). The Portuguese 'Hymno constitucional,' composed by Dom Pedro I. of Brazil, was set aside for 'A Portuguesa.' Scarcely to be called a hymn, 'Yankee Doodle' is the Ameri-

can air, notwithstanding the more recent rival claims of 'Hail Columbia' and 'The Star-spangled Banner,' neither of which has high intrinsic merit or has taken any great popular hold. More like a hymn is the song 'America,' which is sung to the tune of 'God save the King.' The origin of 'Yankee Doodle' is as obscure and disputed as that of 'God save the King.' Most probably the tune is English, and the words by Dr Schuckburgh, an army surgeon, about 1755. During the American revolution, it came extensively into vogue. It was printed in Aird's *Selection of Scotch, English, Irish, and Foreign Airs* (1778), and in Arnold's opera, *Two to One* (1784).

National Park. See YELLOWSTONE, and YOSEMITE. In Canada a domain 26 miles by 10 in extent has been set aside as a national park at Banff in Alberta (by rail 562 miles N.E. of Vancouver and 920 W. by N. of Winnipeg). It embraces one of the most beautiful sections of the Rocky Mountains, contains hot sulphur-springs, has a handsome railway hotel, and is popular as a pleasure-resort. Roger's Pass, 135 miles to the west, and other areas, are also reserved as national parks. See also NIAGARA.

Nations, LAW OF. See INTERNATIONAL LAW.

Nations, LEAGUE OF. See LEAGUE OF NATIONS, PEACE AND INTERNATIONAL ARBITRATION.

Nativity. See ASTROLOGY.

Natrolite, one of the most common of the group of minerals known as *Zeolites* (q.v.).

Natron, or TRONA, an impure sesquicarbonate of sodium, which always contains sulphate and chloride of sodium. It is obtained from the margins of lakes in Egypt, Siberia, Tibet, &c., and from the borders of the Black and Caspian Seas.

Natron Lakes, eight in number, are in a depression to the west of the Damietta branch of the Nile. The locality is renowned for four monasteries, from whose libraries of Arabic, Coptic, and Syriac MSS. various European collections have been enriched. In the time of St Pachomius 5000 anchorites dwelt here.

Natterjack. See TOAD.

Natural History, in its widest and oldest sense, includes all the concrete sciences, but psychology and sociology have been separated off at the one end of the series, physics and chemistry and all their branches at the other, so that natural history became synonymous with the science of living things. Most frequently, however, it simply means zoology, especially in so far as that is concerned with the life and habits of animals. See BIOLOGY, BOTANY, EVOLUTION, SCIENCE, ZOOLOGY.

Naturalisation is the process whereby an Alien (q.v.) is invested with the privileges and made liable to the obligations of a natural-born citizen. It implies the renunciation of one political status and the adoption of another. Formerly many states absolutely refused to recognise any act of naturalisation as exempting the party naturalised from the consequences of his allegiance. Thus, the maxim of English common law, *Nemo potest exuere patriam*, precluded a natural-born subject from adopting a new political status, and rendered him liable to the penalties of treason if found in arms against his native country. The existence of this principle gave rise to many disputes, more particularly between Great Britain and the United States. It was not, however, till the Naturalisation Act of 1870 that the doctrine of the indelibility of natural allegiance was formally abandoned by Britain. In the same year a treaty was entered into between Great Britain and the United States, which provided that British subjects

becoming naturalised in the United States should be treated in all respects as United States citizens; and a corresponding provision was made with respect to United States citizens becoming naturalised in British dominions.

The conditions on which naturalisation will be allowed by the state to which the applicant seeks to affiliate himself vary in different countries. In Great Britain naturalisation is effected either through a special act of parliament or under the British Nationality and Status of Aliens Acts, 1914 and 1918. The Act of 1914, sect. 2 (1), enacts that the Secretary of State may grant a certificate of naturalisation to an alien who makes an application and satisfies the Secretary of State (a) that he has either resided in his Majesty's dominions for a period of not less than five years or been in the service of the crown for not less than five years within the last eight years before the application; (b) that he is of good character and has an adequate knowledge of the English language; and (c) that he intends, if his application is granted, either to reside in his Majesty's dominions or to enter or continue in the service of the crown. Under sect. 2 (2) of the act the residence required is defined as residence in the United Kingdom for not less than one year immediately preceding the application, and previous residence, either in the United Kingdom or in some other part of his Majesty's dominions, for a period of four years within the last eight years before the application. The Act of 1918, sect. 2, provides that a period spent in the service of the crown may be treated as equivalent to a period of residence in the United Kingdom. The grant of a certificate of naturalisation is in the absolute discretion of the Secretary of State. The Acts of 1914 and 1918 contain provisions as to the revocation by order of the Secretary of State of certificates of naturalisation. A certificate of naturalisation does not take effect until the applicant has taken the oath of allegiance. A person on being naturalised is entitled in the United Kingdom to all political and other rights, powers, and privileges, and is subject to all obligations to which a natural-born British subject is entitled or subject. He, under the statutes now in force, does not cease to be a British subject when within the limits of the foreign state of which he was a subject previously to obtaining his certificate of naturalisation, and of which he has not ceased to be a subject by the laws of that state. In *The King v. Speyer*, 1916, 2 K.B. 858, it was held that a naturalised subject born out of the British dominions and not of British parents may validly be appointed a member of the Privy Council. The application for a certificate of naturalisation states the foreign state of which the applicant is a subject, his place of birth, the names and nationality of his parents, his own name, address, age, and occupation, whether he is married and has any children, under age, residing with him (with names and ages), and the details of the requisite period of residence (see British Nationality and Status of Aliens Regulations, 1914 and 1918). The Secretary of State may, on application by the alien, include in the certificate of naturalisation the name of any child of the alien born before the date of the certificate and being a minor. Thereupon such a child, if not already a British subject, becomes a British subject; but he may, within one year after attaining his majority, make a declaration of alienage and cease to be a British subject.

The British Nationality Act, 1914, sect. 8, contains provisions as to the issue of colonial certificates of imperial naturalisation. The government of any British possession has the same power as the Secretary of State to grant or revoke a certificate of

naturalisation. A certificate granted under this section has the same effect as a certificate of naturalisation granted by the Secretary of State. In a British possession other than one of the self-governing dominions this power must be exercised by the governor or a personality under his authority, but is subject in each case to the approval of the Secretary of State. In a self-governing dominion the government of the dominion, after the act has been adopted by the legislature, may make regulations as to how and by what department the power is to be exercised.

In the United States the period of residence required for naturalisation is five years, one of which must have been passed within the state or territory of the court to which application is made. The requisites for naturalisation also include, besides the preliminary residence in the United States, a declaration or oath before a competent court, two years previously to admission, of *bona fide* intention to become a citizen of the United States and to renounce foreign allegiance. An act of Congress of 2d March 1907 provides that when any naturalised citizen shall have resided for two years in the foreign state from which he came, or for five years in any other foreign state, it shall be presumed that he has ceased to be an American citizen; but this presumption may be rebutted on presentation of satisfactory evidence to a diplomatic or consular officer of the United States. It is also provided by the same act that any American citizen shall be deemed to have expatriated himself when he has been nationalised in any foreign state, or when he has taken the oath of allegiance to any foreign state.

The German Imperial and State Nationality Law of 1913 enacts that a German can only lose his nationality, by a definite act showing an intention to sever his connection with his country, and, in particular, that he does not lose his nationality if, before acquiring a foreign nationality, he obtains the written permission of the competent home authorities to retain his German nationality. The effect of this law is to render it almost impossible to say that a German has ever lost his nationality.

The general rule is that a married woman is held to be a citizen of the state of which her husband is for the time being a subject; but the wife of a French citizen, upon the acquisition of a new nationality by her husband, may, if she chooses, retain the nationality possessed by her at the date of the marriage.

Certain privileges of British nationality may be acquired by the issue to an alien of letters of denization granted by the crown; and for this no previous residence is required. The grant may be temporary or conditional, and may either express the privileges conferred or confer all the rights of a naturalised subject. A denizen acquires his privileges as from the date of the letters. The grant is not retrospective, and therefore his children, if born outwith the king's dominions before the issue of the letters, do not acquire British nationality unless expressly included in the terms of the grant.

See *Reports upon the Laws of Foreign Countries* (1893).

Naturalism, a term once used as almost equivalent to Deism, and sometimes for nature-worship, also for brutish defiance of moral law, is now usually employed as synonymous with Realism (q.v.) in art, literary or other.

Natural Philosophy. See PHYSICS, SCIENCE.

Natural Selection. See DARWINIAN THEORY.

Natural Theology. See APOLOGETICS, and THEOLOGY.

Naturism, a derivative of Animism (q.v.) which attributes spiritual being to the various permanent and recurring natural phenomena.

Nau'cratis, an ancient city of Egypt, situated in the Nile delta, near the modern village of Nebireh, 47 miles SE. of Alexandria, existed in the 7th century B.C. It was the only city in Egypt at which the Greeks were allowed to trade, was celebrated for its artistic pottery, and was a centre for the worship of Aphrodite. The site was discovered by Flinders Petrie in 1884. His monograph *Naukratis* (1886) gives an account of the ruined temples and the many valuable archaeological discoveries made on this site. See also *The Annual of the British School at Athens* (1898-99).

Naugatuck, in Connecticut, on the Naugatuck River, 22 miles by rail NNW. of New Haven, manufactures gloves, rubber, cutlery, and iron-wares; pop. 15,000.

Nauheim, or BAD NAUHEIM, a watering-place of Upper Hesse, renowned for its medicinal springs.

Naumachia, a Greek word signifying literally a naval battle; afterwards, among the Romans, a spectacle which consisted in the imitation of a naval battle. Julius Cæsar was the first to introduce a naumachia into Rome, 46 B.C., causing a portion of the Campus Martius to be dug to form a lake, on which the spectacle came off. Augustus also made an artificial lake near the Tiber for the same purpose, and Claudius employed Lake Fucinus, where on one occasion 19,000 combatants were engaged for this purpose. The combatants were for the most part either captives or condemned criminals. These *naumachie* were not *sham-fights* any more than were ordinary gladiatorial combats; both sides fought on in real earnest for dear life until one was utterly overpowered.

Naumburg, a quaint old town of Prussian Saxony, on the Saale, in an amphitheatre of vine-clad hills, 30 miles by rail SW. of Leipzig. Of its six churches, the triple-towered cathedral (1207-42) is a noble Romanesque and Gothic structure. The manufactures include ivory carvings, combs, hosiery, &c. The yearly 'cherry feast' commemorates the raising of the siege of Naumburg by the Hussite leader Procopius in response to the supplication of the children (28th July 1432); but recent historians cast doubt on the whole episode. The seat of a bishopric (1059-1564), Naumburg suffered much in the Thirty Years' War; in 1814 it came to Prussia. Pop. (1875) 16,258; (1919) 28,545.

Naupactus. See LEPANTO.

Nauplia, a small town and seaport with an excellent roadstead in the Peloponnesus, Greece, at the northern extremity of the Gulf of Argos or Nauplia, 25 miles S. of Corinth. At an early period it was the port and arsenal of Argos. In the 13th century it was occupied by the Venetians (who called it Napoli di Romania), and it was taken by the Turks in 1540. From 1824 to 1835 it was the capital of Greece, and had a population of upwards of 12,000; but on the removal of the court to Athens it fell into decay. Pop. 4000.

Nauplius. See CRUSTACEA.

Nauru, a Pacific atoll in 0° 15' S. lat., 167° E. long., with a valuable phosphate deposit, was German from 1888 to 1914, when it was taken by the Australians. The Treaty of Versailles placed it under a mandate of the British Empire (Great Britain, Australia, and New Zealand jointly). Area, 8 sq. m.; pop. 2000 (one-half native).

Nausea is a distressing sensation always referred to the stomach. It is unattended by pain, but is usually accompanied by a feeling of general languor or debility, a small and often irregular pulse, a pale, cool, and moist skin, general mus-

cular relaxation, an increased flow of saliva, and a sensation that vomiting will supervene. It is most commonly a *direct* symptom of disease or disorder of the stomach, but sometimes it is a very important *indirect* symptom of disease of some part at a distance from the stomach—as, for example, the brain or the kidney. The nausea which is so troublesome to pregnant women is due to the irritation excited by the enlarged uterus being reflected by nervous agency to the stomach. Seasickness is separately discussed.

Nausicaa, a charming female character of Homer's *Odyssey* who hospitably entertained the shipwrecked Odysseus at the court of her father Alcinoüs, king of the Phæacians.

Nautch Girls, or BAYADERES, public female dancers in India and the East Indies. Their performances constitute a principal part in the spectacular entertainment called a nautch or natch.

Nautical Almanac See ALMANAC.

Nautilus, a remarkable mollusc in the class of Cephalopods, the only surviving member of a race once abundant. It differs conspicuously from the other extant Cephalopods or 'cuttle-fish' in possessing a shell, within the outermost chamber of which it lives, while the lobes of the 'foot' round about the mouth bear numerous tentacles retractile into sheaths, the 'siphon' consists of two free folds, the eyes are open sacs without cornea or lens, there are four gills and four kidneys, and there is no ink-bag. The spiral shell, coiled in one plane like that of the water-snail Planorbis, differs from this in being chambered; moreover, the foot or ventral side of the enclosed animal is towards the outside in Nautilus, towards the inside in Planorbis. When young the Nautilus lives in a small shell bent like a horn; with growth this is increased spirally, but as the animal periodically draws itself onwards and closes a door behind it, a chambered spiral results, in which the original shell is in the very centre. The successive chambers are all connected, however, by an organic, partially calcareous tube; and all except the outermost, in which the animal lives, are filled with gas—apparently a mixture of oxygen and nitrogen somewhat different from air. The outside of the shell is covered with a thin

Fig. 1.—Pearly Nautilus (after Owen). Contracted spirit specimen, with the shell in section:

a, dorsal 'hood'—a portion of the 'foot'; b, a portion of the mantle reflected on the shell; c, tentacles; d, eye; e, ventral side of visceral hump; f, funnel; g, a partition between two chambers; s, siphuncle or tube traversing the chambers.

organic layer, beneath which there is a porcelain-like stratum with bands of colour, while internally the lime has the usual mother-of-pearl structure, the lustre of which, often artificially exposed by the use of acids, has earned for the animal its common name of Pearly Nautilus.

Though the Nautilus seems to have been known to Aristotle, and though the shells have always been familiar, the animal itself is rare. The rarity of specimens, so evident from the fact that only one was collected on the *Challenger* expedition, is mainly due to its habitat in somewhat deep water. But it must also be noted that the natives of Fiji, the New Hebrides, the Moluccan Islands, &c. catch the animal in lobster-pots and eat it with relish. Dr Willey studied the Pearly Nautilus in New Britain (Neu Pommern), where he kept them in cages in the sea. The Nautilus probably creeps or gently swims along the sea-bottom, feeding on crustaceans and the like; but it is also seen floating on the surface, probably washed up by storms and injured by the waves. The species best known is *Nautilus pompilius*, but there are probably four or five others, while the fossil relatives are reckoned in hundreds.

The *Paper Nautilus* (*Argonauta*) is a very different animal, like an octopus except that the

Fig. 2.—Female Paper Nautilus, showing the two modified arms which make and embrace the shell.

female bears a beautiful, translucent, ribbed shell in which the eggs are sheltered. But this shell is not in any way comparable to that of the Nautilus or of other molluscs; it is a cradle, not a house; it is secreted and embraced by two broadened dorsal 'arms,' not by the mantle; it is unchambered and peculiar to the females. The Argonaut was credited by Aristotle with the power of lifting its broad arms, and of thus sailing before the wind, but there is no truth in this fancy often reiterated by poets and naturalists. For the Argonaut squirts water from its funnel and swims backwards like any other cuttle-fish, or else creeps along the bottom. At the breeding season it is a pelagic surface swimmer in tropical seas, at other times it seeks the depths. The male measures little more than an inch in length, only about a tenth of the size of his mate, and he is also notable for the modification of one of the arms into a detachable sac of spermatozoa, formerly mistaken for a parasitic worm. Some half-dozen living species are recorded. See CEPHALOPODA, CUTTLE-FISH.

Nauvoo' (Heb., 'beautiful'), a city of Illinois, on the Mississippi, in a fertile fruit-growing country, 14 miles above Keokuk. It was built by the Mormons (q.v.) in 1840, and in a few months contained a prosperous population of 15,000. Its principal feature was a great temple of white limestone (1845). After the expulsion of the Mormons in 1846, the temple was ruined by a fire and a tornado. The town was for a time occupied by French Socialists, and has now only 1000 inhabitants.

Navajo, an American Indian tribe of Arizona and New Mexico, of Athabaskan speech, long marauders, are now peaceful horse-breeders and

blanket-weavers. Their traditions go back to the 14th century. They give their name to a county in Arizona.

Naval Reserve. See NAVY.

Navan, a market-town in Meath, at the junction of the Boyne and Blackwater, 16 miles W. of Drogheda; pop. 4000.

Navarino (officially *Pylos*), a town of 2000 inhabitants, with a good harbour, on the SW. coast of the Morea, near the ancient Pylos, the city of Nestor. The Bay of Navarino was the scene of a great sea-fight between the Athenians and Spartans (425 B.C.), in which the latter were defeated; and on the 20th of October 1827 it saw the Turkish and Egyptian navies annihilated by the combined British, French, and Russian fleets under Codrington.

Navarre, once a kingdom in the Pyrenees, but since 1512 divided into Spanish Navarra and French Navarre (now Basses Pyrénées). Spanish Navarra, by far the greater, between France, Aragon, Castile, Alava, and Guipúzcoa, has an area of 4000 sq. m. and a pop. of 312,000. It is one of the most varied provinces of Spain in surface and climate; at its north-west corner the rainfall is one of the heaviest in Europe, while in the south-east the steppes of the Bardenas Reales are almost sterile for want of water. The mountains of the northern frontier range, west to east, from 3000 to 8000 feet of altitude. With the exception of the Bidassoa, which enters the Atlantic at the inner angle of the Bay of Biscay, the numerous other streams flow at right angles to the Pyrenees, and are all affluents of the Ebro; the principal are the Aragon, Arga, and Ega. The mountain-valleys are narrow but fertile. By the energy of the Basques, who do not live like the Spaniards only in towns and villages, cultivation is carried on almost everywhere. The chief productions are maize, wheat, chestnuts, apples, and a strong red wine. Cattle abound, but not many sheep or horses. Minerals are found in the Pyrenees, and mines of argentiferous lead, copper, and iron are worked; rock-salt also is found in the province. The wild animals include the bear, wolf, roe-deer, ibex, in the mountains of the Aragonese frontier; foxes, wild cat, genet, otter, marten, &c. are in sufficient numbers to make commerce of their skins. The population of Navarre is generally bilingual; from a little to the south of Pamplona northwards Basque prevails; to the south Spanish only is spoken. Until now Spanish has encroached far more on Basque in Navarra than has French in Basse-Navarre.

History.—In Roman times the country now called Navarre was occupied by the Iberian Vascones, who have given their name both to Basques and Gascons. Within historic times there has been a strong Celtic element in the country. The capital, Pamplona (*Pompeopolis*), recalls the Roman Triumvir, but the older native name, Irun (*Irunean*), is often on books printed at Pamplona. The subjection of the Vascones to the Visigoths was nominal only. On the downfall of the latter and the incursion of the Arabs the mountains of Navarre became one of the early centres of resistance and of reconquest. From the native chiefs, or counts, arose the first dynasty of Navarre—Garcia Jimenez (860) to Sancho the Strong (1234). The history of Navarre is full of interest. In 778 the rout of Charlemagne's rear-guard, and the death of Roland at Roncesvalles, furnished a theme for countless poems and romances. With Aragon and Castile Navarre shares the honour of being one of the first countries in which parliamentary rule with representation of towns and commons (*Universidades*) obtained. The Cortes (*Curiae*) arose out of the Councils, and there was regular represen-

tation of the three orders before the close of the 12th century. During this period Navarre gained its name and modern limits, but under Sancho the Great (1028-35), and again (1109-34) under Alfonso I., it seemed as if the union completed under Ferdinand and Isabel would have taken place three or four centuries earlier. Sancho the Strong left no male heirs, and the future succession of Navarre was singularly broken from the same cause. The crown passed to Thibaut, count of Champagne, through the younger daughter. There were three kings of this house from 1234-84, when the crown passed by marriage to Philippe le Bel of France. Five kings of France (1284-1328) reigned over Navarre, when, through the female succession, it passed to Philippe, count of Évreux; three kings of this line succeeded—Philip III., Charles II. the Bad, and Charles III. Under them Navarre reached its highest prosperity; most of the architectural beauties of Navarre date from this period, 1328-1416. Navarre had been always closely connected with Aragon, and three of its kings had already borne the title of Aragon and Navarre. Blanca, the daughter of Charles III., married first Martin, king of Sicily, and after his death Juan II. of Aragon. Civil war arose between him and his son, Don Carlos, Prince of Viana, one of the most interesting characters of his time. The factions of Beaumont (Don Carlos) and of Agramont (Juan II.) proved the ruin of Navarre. Henceforth her jealous neighbours could always rely on the support of one or other in their encroachments. Leonor, the daughter of Juan II., married Gaston of Foix, and thus Navarre became united to Béarn; her granddaughter, Catharine de Foix, married Jean d'Albret in 1486, and during their reign in 1512 the Duke d'Alba conquered Navarre, which has since been united with the Spanish crown. French Navarre was joined to that of France by the accession of Henri of Navarre in 1589, but the formal union was not completed until 1620 by Louis XIII. After its union Spanish Navarre was governed by a viceroy, and retained its own cortes, mint, style of kings (Carlos III. of Spain was VI. of Navarra, &c.), power of taxation, and *Fueros* (q.v.). These privileges were almost wholly lost by the first Carlist war (1833-39), and were still more diminished by the second (1872-76). Navarre is now one of the forty-nine provinces of Spain, with merely local self-government in minor matters in certain districts. In France Basse Navarre preserved its *fueros* till 1789, refused to send deputies to the States-general as part of France, and declared that it would only accept the new constitution if it were better than its own. The *fueros* of Navarre are more like those of Aragon than those of the Basque Provinces. In their written form they are probably not older than the 13th century, but many provisions point back to a higher antiquity. The seven *Fazanas* (precedents) are in the form of apologies, animals are considered as morally responsible and guilty of homicide towards each other, marriage is a civil right, the children of a concubine (*barragana*) are provided for, compurgation is in full force, and social excommunication is inflicted on those who will not conform to the customs. Toleration is extended to Moors and Jews, and the oath to be taken by the latter is very long and curious. In the Cortes the power of taxation was secured by supplies being withheld until all grievances had been redressed. With consent of the Cortes the king might amend, but could not impair the *fueros*. Navarre was a frontier of the English possessions in south-west France from 1152 to 1453. Richard I. and Henry IV. married princesses of Navarre; had the former had issue, they would have been heirs of Navarre in preference to the counts of

Champagne. Charles the Bad was the ally of the Black Prince, who passed through his dominions to Navarrete. Wellington blockaded Pamplona, and marched through Navarre in 1813-14.

See P. J. Moret, *Investigaciones Historicas del reyno de Navarra* (1 vol. 1665) and *Anales del reyno de Navarra* (3 vols. Pamplona, 1684)—both reprinted by E. Lopez of Tolosa in 1890-91; Tanguas, *Diccionario de las Antigüedades de Navarra* (4 vols. Pamplona, 1840-43); *Fuero General de Navarra* (Pamplona, 1869); *La Navarre Française*, par M. G. B. de Lagrèze (2 vols. Paris, 1881); the decisions of the Cortes under title *Quaderno de las Leyes y Agrarios Reparados*, &c., vol. vii., and V. de la Fuente, *Estudios Críticos sobre la Historia y el Derecho de Aragon*, vols. i. and ii. (Madrid, 1884-85).

Navarrete, JUAN FERNÁNDEZ, a Spanish painter, born at Logroño in 1526, died at Toledo in 1579. Losing his powers of hearing and speech at an early age, he developed a marked aptitude for sketching, and was sent to study art at Estrella. Navarrete, called El Mudo ('the mute') from his physical affliction, sojourned in Italy, where he was a pupil of Titian, and finally returned to Madrid, becoming in 1568 the royal painter to Philip II. He left many paintings at the Escorial, notably his 'St Jerome' and 'Holy Family.' His 'Nativity' and 'Abraham receiving the Three Angels' are worthy of notice. See Stirling-Maxwell, *Annals of the Artists of Spain* (1891).

Nave. See CHURCH, GOTHIC ARCHITECTURE.

Navelwort (*Cotyledon Umbilicus*), a plant of the family Crassulaceae, characteristic in Britain of the west coast, where it grows on walls and rocks. It takes its names from the concave peltate fleshy leaves. The pendulous flowers are yellowish-green. To the same genus belong about 100 species in the Old World, Mexico, and South America.

Navev (Fr. *navette*), a garden vegetable much cultivated in France and other parts of the continent of Europe, although little used in Britain. *Brassica Napus*, or Rape (q.v.), is regarded as a cultivated variety of *B. campestris*, sometimes called Wild Navev, the species which is also supposed to be the original of the Swedish Turnip (q.v.). But the relationships of these long-cultivated plants are obscure. The part used is the swollen root, which is rather like a carrot in shape. Its colour is white. Its flavour is much stronger than that of the turnip. It succeeds best in a dry, light soil. The seed is sown in spring, and the plants thinned out to 5 inches apart. *Wild Navev* is extensively cultivated in the north of France and Holland for the sake of its seed, which yields Colza oil.

Navicular Disease, in the horse, consists of an inflammation, often of a rheumatic character, of the small bone—the navicular—below which passes the strong flexor tendon of the foot and the bursa between them. It is most common among the lighter sorts of horses, especially when they are given early and severe work on hard roads. It soon gives rise to a short tripping yet cautious gait, undue wear of the toe of the shoe, and projecting or 'pointing' of the affected foot whilst standing. Even when early noticed and in horses with well-formed legs, it is often incurable; and when of several weeks' standing it leads to so much inflammation and disease of the tendon and adjoining parts that soundness and fitness for fast work again are seldom attained. In order to reduce the pain and inflammation, rest should at once be given, the shoe removed, the toe shortened, and the foot placed in a large, soft, hot poultice, changed every few hours. Laxative medicine and bran mash should be ordered, and a soft bed made with short litter. After a few days, and when the heat and tenderness abate, cold applications should supersede the hot; and after another week a blister may be

applied round the coronet, and the animal placed for two months in a good yard or in a grass field, in which the ground is soft and moist, or, if strong enough, at slow farm-work on soft land. Division of the nerve going to the foot removes sensation, and is useful in relieving animals intended for slow work. It often enables young animals with good feet to work sound for years, but is not to be recommended in older animals where fast work is required, for the animal, insensible to pain, uses the limb as if nothing were amiss, and the disease rapidly becomes worse. Navicular disease is very often hereditary; hence horses suffering from it should never be used for breeding purposes.

Navigation Laws. The importance of the early maritime codes in developing International Law is indicated in that article. Laws restricting foreign trade and supposed to be in favour of native commerce and shipping are of very ancient date. Thus, in England, by a statute of Richard II., in order to augment the navy of England, it was ordained that none of the lieges should ship any merchandise out of the realm except in native ships, though the statute was soon evaded and seldom followed. At length in 1650 an act was passed with a view to stop the gainful trade of the Dutch. It prohibited all ships of foreign nations from trading with any English plantation without a license from the Council of State. In 1651 the prohibition was extended to the mother-country, and no goods were suffered to be imported into England or any of its dependencies in any other than English bottoms, or in the ships of that European nation of which the merchandise was the genuine growth or manufacture. At the Restoration these enactments were repeated and continued by the Navigation Act (12 Char. II. chap. 18), with the further addition that the master and three-fourths of the mariners should also be British subjects. The object of this act was to encourage British shipping, and was long believed to be wise and salutary. Adam Smith, however, perceived that the act was not favourable to foreign commerce or to opulence, and it was only on the ground that defence was more important than opulence that he said it was 'perhaps the wisest of all the commercial regulations of England.' In 1826 the statute 4 Geo. IV. chap. 41 repealed the Navigation Act, and established a new system of regulations, which were further varied by subsequent statutes, till, under the influence of the free-trade doctrines, new statutes were passed which reversed the ancient policy. It was not, however, till 1854 that the English coasting trade was thrown open to foreign vessels. In the United States the coasting trade is reserved exclusively to American vessels. As regards those laws of navigation which affect the property and management of ships, a complete code of regulations is contained in the Merchant Shipping Acts.—On navigation, see GEOGRAPHY, LATITUDE and LONGITUDE, GREAT CIRCLE SAILING, &c.

Navigators' Islands. See SAMOA.

Naville, HENRI ÉDOUARD, was born at Geneva in 1844. Educated at the universities of Bonn, Paris, and Berlin, he devoted himself from 1883 to Egyptian excavation. He is the author of many books on the subject, especially on its religious side, among them being *La religion des anciens Égyptiens* (1906), *L'Évolution de la langue égyptienne et des langues sémitiques* (1920), *The Law of Moses* (1920).

Navy. The ancient method of naval warfare consisted in great part in the driving of beaked vessels against each other; and therefore skill and celerity in manœuvring, so as to strike the enemy at the greatest disadvantage, were of the utmost importance. The victory thus usually remained

with the best sailor. These vessels were propelled by oars, which were arranged in one, two, or three banks, according to size of ship; the oars were manned by men sitting or standing on platforms arranged above each other according to the number of banks; those with three banks of oars were called triremes. The earliest powers having efficient fleets appear to have been the Phœnicians, Carthaginians, Persians, and Greeks; the Greeks had fleets as early as the beginning of the 7th century B.C.—the first sea-fight on record being that between the Corinthians and their colonists of Corcyra, 664 B.C. The earliest great battle in which tactics appear to have distinctly been opposed to superior force, and with success, was that of Salamis (480 B.C.), where Themistocles, taking advantage of the narrows, forced the Persian fleet of Xerxes to combat in such a manner that their line of battle but little exceeded in length the line of the much inferior Athenian fleet. The largest triremes in the Persian fleet were manned by 200 rowers and 30 fighting-men; there were 1200 triremes and 3000 smaller vessels, while the Greek fleet consisted of 366 triremes only, with a certain proportion of smaller vessels, yet they succeeded in inflicting a crushing defeat on the Persians. The Peloponnesian war, where 'Greek met Greek,' tended much to develop the art of naval warfare. But the destruction of the Athenian maritime power in the Syracusan expedition of 414 B.C. left Carthage mistress of the Mediterranean. The Roman power, however, gradually asserted itself, and after two centuries became omnipotent by the destruction of Carthage; the greatest Roman sea-fight was that of Actium (q.v.) in 31 B.C. Gradually fighting with pointed prows was discontinued in favour of running alongside and boarding. Onagers and ballistæ were also carried in the ships and used as artillery.

The northern invaders of the empire, and subsequently the Moors, introduced swift-sailing Galleys (q.v.), warring both in small squadrons and singly, and ravaging all civilised coasts for plunder and slaves; the Norsemen penetrated in every direction from the Bosphorus to Newfoundland. As a defence against these marauders, the mediæval navies gradually sprang up. In the 16th century, so powerful was the Turkish fleet that a combination of the Christian powers was formed for self-defence; and in 1571 the battle of Lepanto (q.v.) broke the naval power of the Turks. Thereafter the Venetian and Maltese fleets became the most powerful; but by the 17th century naval power was falling into the hands of the English, French, Dutch, and Spaniards.

The destruction of the Spanish Armada in 1588 by the English fleet placed Great Britain in the front rank of naval powers, while Spain received a blow from which she never completely recovered. The Commonwealth and reign of Charles II. were signalised by the struggle for mastery between the English and Dutch; but victory finally sided with the former. In the 18th century Great Britain and France were the two great rivals, and during the American War of Independence the naval power of this country was seriously threatened. The Dutch and Spanish fleets were still formidable, and Russia as a naval power added a new element of danger. Camperdown broke the Dutch power; many disastrous battles weakened the French navy; and at Trafalgar in 1805 the French and Spanish navies were swept temporarily from the ocean, leaving Great Britain the mastery of the seas.

MODERN NAVIES.—*France.*—Soon after the peace of 1815 the French fleet was again brought up to its old strength. France was the first country to commence the construction of an ironclad fleet by the launch of the armoured frigate *Gloire* at Toulon in 1859, and from that date up to 1889 the French

armoured fleet was a formidable rival to our own. But from the passing of our Naval Defence Act in 1889 her navy dropped steadily behind—a result brought about partly by the refusal of the French chambers to vote the necessary money, and partly because a powerful school had been advocating the building of nothing but cruisers, believing that a 'corsair war,' directed solely against her trade, would prove the most effective weapon in the event of a war with Great Britain. But in 1899 the then Minister of Marine and the Superior Council of the Navy placed on record their opinion that the 'minimum' number of first-class battle-ships France required was twenty-eight, organised in four squadrons of six ships each, with a spare ship for each division; that as each division of six ships was completed a new division should be laid down until by 1916 the full number should be made up, and pace would thus be kept with the latest German programme. The chambers sanctioned in 1900 the commencement of a new programme providing for the construction of six powerful battle-ships, besides cruisers and smaller vessels. France has given the lead to all countries in the matter of submarines (see SUBMARINE NAVIGATION).

United States.—From the commencement of the War of Independence the Americans began to build a fleet, and during that war and the war of 1812-14 they maintained on the sea a glorious, although unequal, struggle with Great Britain. The Secession in 1860 found the navy at a low ebb, and the vessels built in the next four years were mostly gunboats for blockading and monitors (see below) for coast and river work. During the twenty years after the war the navy was again much neglected, but since 1887 great efforts have been made to construct a new fleet of the most formidable character. In the war with Spain in 1898 the United States squadrons in China and the West Indies easily annihilated those of Spain. Since then the United States has embarked on a more ambitious building programme, which had by 1914 raised her to the third place among the great naval powers, and has now put her second to Great Britain.

Germany.—The German navy dates from the acquisition of Kiel by Prussia after the war with Denmark in 1864. The fleet was too weak to count in the war with France in 1870; and although from that time on it increased steadily, it was not until after 1895 that Germany showed any determination to become a great naval power. From his accession in 1888 the Kaiser William II. insisted that a powerful fleet was essential not only to the interests but to the future existence of the German empire. But it was only after 1896 that he was able to bring the Reichstag and people round to his views. In 1898 a Naval Act was passed fixing the strength of the future German fleet at thirty-eight first-class battle-ships—four squadrons of eight ships each, with a spare ship for each squadron, and two additional ships as flag-ships, with cruisers and torpedo-boat destroyers. The new programme was to be completed in 1916, but in 1914 the Great War found the German fleet but little inferior in material to the British fleet except in matter of submarines; it was actually numerically superior in torpedo craft and in mines and mine-layers.

Russia.—The Russian navy was founded by Peter the Great, but has never had much opportunity of distinguishing itself. In 1853 the bulk of the Black Sea fleet was sunk in order to block the entrance to the harbour of Sebastopol, and the remaining ships were burnt when the Russians evacuated the town in 1855. By the abrogation of the Black Sea clauses of the treaty of Vienna in 1871 Russia re-

gained a free hand; and although during the war with Turkey (1877-78) her fleet was unable to make head against that of Turkey, from 1890 Russia's naval force in those waters dominated the Dardanelles and Constantinople. The Russian fleet steadily increased, so that in 1904, at the outbreak of the war with Japan, it stood next to that of the United States. But from the beginning the Japanese proved more than a match, and in and about Port Arthur and Vladivostok annihilated the Pacific fleet.

Italy.—The Italian navy dates from the absorption of Naples by Sardinia in 1860. After the disastrous defeat of the Italian fleet off Lissa by the Austrians in 1866, successive Italian governments devoted large sums towards building up a powerful navy, and in 1893 Italy could fairly claim to rank as a first-class naval power, next to France. But owing to financial difficulties, Italy had so far fallen behind that in 1914 her fleet ranked below those of the United States and Germany.

Austria-Hungary.—The Austrians from 1840 possessed a small navy, but for its size one of the most efficient, as was shown during the war of 1866, when the numerically and generally inferior fleet under Tegethoff annihilated the Italian under Persano off Lissa.

Turkey.—The Turkish navy, once the terror of the Mediterranean, sustained at Navarino (q.v.) in 1827 a crushing defeat, from which it never recovered. In 1853 a division of the Turkish fleet was completely destroyed by a superior Russian force at Sinope; but as a result of the restrictions imposed on Russia after the Crimean war, and of the energy infused into Turkish naval administration by Hobart Pasha, in 1877 the Russian fleet was paralysed by the superior Turkish force, which retained command of the Black Sea during the war.

Spain.—Unlike France, Spain never recovered from the blow inflicted at Trafalgar. The war with the United States in 1898 proved disastrous to Spain, her four finest armoured cruisers and several smaller ships being destroyed or captured in the battles of Manila Bay (April) and Santiago de Cuba (July); and in 1904 one first-class battle-ship was all that was left to the country which once held the undisputed mastery of the sea.

Japan.—Japan has swiftly become a naval power to be reckoned with, as was triumphantly shown from the beginning of the war with Russia. Even before the civil war of 1868-69, the government had recognised the necessity of creating a fleet on the European model, and had applied to the English government for some officers to be lent as instructors; and in 1867 a picked staff of officers and petty officers was sent out. A naval college was organised; the Japanese, both officers and men, proved apt pupils; dockyards were constructed at Yokosuka and at Nagasaki, and so well organised that in 1875 they were able to dock large warships at Yokosuka, the whole work being carried out by the Japanese employees of the yard. In 1878 a corvette was cruising in European waters, which was built at Yokosuka to Japanese designs, by Japanese workmen, everything about her, including the engines and guns, being turned out in the country, and she was manned entirely by Japanese officers and men. In the war with China (1894-95) the smaller and weaker Japanese fleet destroyed or captured that of China, though the officers and men of the Chinese fleet had been well trained by English officers. At the battle of the Yalu the Japanese ships were manœuvred with great skill. In the war with Russia in 1904-5 the interest largely centred in the steps by which the Japanese fleet secured the command of the seas, and ultimately shut up the Russian Pacific fleet in Port Arthur and Vladivostok.

THE BRITISH NAVY.—Alfred the Great was the founder of the English navy; an advantage gained by some ships of his over the Danes in 876 induced him to build long ships and galleys, which, as his countrymen were not competent to manage them, he partly manned with piratical foreigners. After he had driven out the Danes he built vessels higher, longer, and swifter than before, some rowing more than thirty pairs of oars. Under his successors the number of vessels increased, and both Edward the Elder and Athelstan fought many naval battles with the Danes. Edgar aspired to be lord of all the northern seas, and had from three to five thousand galleys, which he divided into three fleets, on the western, southern, and eastern coasts respectively. Ethelred II. enacted that every owner of 310 hides of land should build and furnish one vessel for the service of his country. When the right to press private ships for the service of the crown originated is not clear, but in 1049 a fleet of Edward the Confessor consisted partly of 'king's ships' and partly of 'people's ships.' William the Conqueror established the Cinque Ports, and gave them certain privileges, on condition of their furnishing fifty-two ships for fifteen days, carrying twenty-four men each, in case of emergency. Richard I. took one hundred large ships and fifty galleys to Palestine, and it was he who at 'Grymmesby,' by the advice of 'many lords of the Realme,' issued the first known ordinance empowering the 'Admiral' to seize private ships for the public service, and fixing a 'yeare's imprisonment' as the punishment for the crime of desertion. King John claimed for England the sovereignty of the seas, and required all foreigners to strike to the English flag, an honour which was exacted by the English admiral off Southampton Water from the fleet bringing Philip II. of Spain hither to espouse Queen Mary. This honour was formally yielded by the Dutch in 1673 and the French in 1704, but the custom fell into disuse after the peace of 1815. In 1293 a great naval action was fought in mid-Channel with the French, when the English captured 250 sail; and Edward III. with the Black Prince at Sluys in 1340 defeated a greatly superior French fleet. It was Edward III. who first appointed a 'High Admiral of all the Fleets,' Sir John de Beauchamp being the first holder of this high office, and it was also in his reign that the first authentic records as to the mounting of guns in some of the ships of the fleet appear. In the Public Record Office is an 'Indenture between the Clerk of the ships, galleys, &c. and the Keeper of the same, supplying to the latter, among certain other stores for the ship called the *Bernard de la Tour*, two iron guns; also to the *Marie de la Tour*, one iron gun of two chambers, and another of brass.' In the reign of Richard II. parliament passed the first statute legalising 'pressing for the king's navy,' and laying down penalties for desertion. This act was held to be still in force in a case tried at Bristol in 1743, when the legality of pressing men for the king's navy was upheld.

Henry V. added to the navy; but Henry VII. seems to have been the first king who thought of providing a naval force which might be at all times ready for the service of the state. He built the *Great Harry*, the largest ship yet constructed for the royal navy. She cost £15,000, and was accidentally burned in 1553. To Henry VIII., however, belongs the honour of having laid the foundation of the British navy as a distinct service. He constituted the Admiralty and Navy Office; established the Trinity House, and the dockyards of Deptford, Woolwich, and Portsmouth; fixed regular salaries for the admirals, captains, and sailors; and made the sea-service a distinct profession. In 1512, when a fleet was fitted out against France

under Sir Edward Howard, Lord High Admiral, the following allowances were made: for his own diet, maintenance, wages, and rewards per diem, 10s.; each captain for his own diet, maintenance, wages, and rewards per diem, 1s. 6d.; every soldier, mariner, and gunner for his wages per lunar month, 5s., and for his victuals, 5s. In 1515 King Henry caused the *Henri Grace-à-Dieu*, of about 1000 tons and carrying 122 guns, to be constructed, in emulation of a somewhat similar ship called the *Caracon*, but only carrying 100 guns, which had lately been built by Francis I. of France. She appears to have been built rather for magnificence than for use; only thirteen of her guns were 9-pounders or upwards, and she is

Fig. 1.—The *Great Harry*.

said to have steered badly and rolled heavily. After making one voyage, she was disarmed at Bristol and suffered to decay. The French ship was still more unfortunate, being accidentally destroyed by fire at Havre. The ships of this period were high, unwieldy, and narrow, with lofty poops and forecastles, while their guns were very close to the water. At the death of Henry VIII. the tonnage of the navy was 12,000 tons; and there were some fifty ships, manned by 8000 men. Elizabeth increased the fleet greatly. The fleet which met the Spanish Armada numbered 176 ships, armed by 14,996 men; but these were not all 'shippes royal,' for she encouraged the merchants to build large ships which were as much fighting-ships as traders, and rated at 50 to 100 tons more than they measured. She raised the wages of seamen to 10s. per month. Signals were first used in this reign as means of communication between ships. In the reign of James I. lived the first able and scientific naval architect, Phineas Pett; he introduced a better system of building, and relieved the ships of much of their top-hamper, abolishing the lofty poops and forecastles. In 1610 he laid down the *Prince-Royal*, a two-decker carrying sixty-four guns; and in 1637 from Woolwich he launched the celebrated *Sovereign of the Seas*, the first three-decker and the largest ship hitherto constructed on modern principles. She was 232 feet in length, of 1637 tons, and carried at first 130 pieces of cannon. Being found unwieldy, she was cut down, and proved an excellent ship, but was burned in 1696. In this reign the navy was first divided into rates and classes. Cromwell left 154 sail, measuring 57,643 tons, of which one-third were two-deckers. He was the first to lay before parliament annual estimates for the support of the navy, and obtained £400,000 for that purpose. During the Protectorate Peter

Pett, son of Phineas, built the *Constant Warwick*, the earliest British frigate, from a French design and pattern. The Duke of York, afterwards James II., assisted by the celebrated Samuel Pepys, as Secretary, did much for the navy. He appointed a new commission when he came to the throne, with which he joined Sir Anthony Deane, the best naval architect of the time, who essentially improved the ships of the line by copying from French models. At this time, and during the 18th century, naval architecture was zealously studied in France, and the English constructors were so sensible of their inferiority that even up to the beginning of the 19th century all our best ships were either captured from the French or copied from them. At the Revolution of 1689 the fleet was in excellent condition, with sea stores complete for eight months for each ship. The force consisted of 184 vessels, carrying 6930 guns and 42,000 men, whereof nine were first-rates.

William III. added greatly to the navy, which numbered at his death 272 ships of 159,020 tons, the annual charge being £1,056,915. The dockyard at Hamoaze, out of which has since grown the considerable town of Devonport (q.v.), was also established during his reign (see also the article DOCKYARDS, ROYAL).

At the death of Queen Anne in 1714 the number of ships was less, but the tonnage relatively greater, there being 198 ships, carrying 10,600 guns, the tonnage being 156,640. In 1747 a naval uniform was first established. The navy increased rapidly during the reigns of the first two Georges, and at the accession of George III. consisted of 127 ships of the line and 198 of fifty guns and under, measuring 321,104 tons, and manned by 70,000 seamen and marines. The navy was kept in a high state of preparation, and when, in February 1793, the French Republic declared war against England, in a few weeks fifty-four sail of the line and 146 smaller vessels had put to sea completely equipped. The whole fleet in 1793 consisted of 122 ships of the line, 97 frigates, and 102 sloops and smaller vessels, manned by 85,000 seamen and marines. The navy of France had never been so powerful; it amounted to above 200 vessels, of which 82 were of the line, and 71 were in addition ordered to be built. The English had about 115 sail of the line fit for service; but the majority of the French ships were larger and finer, and carried heavier guns on their lower or principal battery. The following abstract will show the losses on both sides up to the peace of Amiens (1802).

Spanish " ".....	57	10
Grand total.....	443	76

This estimate does not include 807 privateers, chiefly French, taken and destroyed. Of the above, 50 sail of the line and 94 under that size were added to the British navy.

During the peace of Amiens preparations for war were actively continued on both sides, and when war broke out again in March 1803 the British fleet consisted of 153 ships of the line and 411 under that size, manned by 120,000 seamen and

marines. 'In the year 1809,' to quote the words of Alison, 'the British fleet was at the zenith of its power, and Great Britain first appeared in the field on a scale adequate to her mighty strength. With a fleet of near 1100 vessels, including 240 of the line, manned by 140,000 men, she blockaded every hostile harbour in Europe, and still had 37 ships of the line to strike a blow at the Scheldt. With 100,000 regular troops she maintained her immense colonial empire; with 191,000 more she ruled India; with 400,000 militia she guarded the British Isles; while her fleet could convey yet another 100,000, with which she menaced, at once, Antwerp, Madrid, and Naples; while Lord Minto, the Governor-general of India, announced in his despatches with well-founded pride that "from Cape Comorin to Cape Horn a French flag could nowhere be found flying."'

The following abstract shows the losses on each side from 1803 to the end of the war, during which 33 sail of the line and 68 under were added to the British navy.

Since the peace in 1815 the number of vessels has been greatly diminished, although their power has vastly increased.

The progressive augmentation of size in vessels may be judged from the increase in first-rates. In 1677 the largest vessel was from 1500 to 1600 tons; by 1720, 1800 tons had been reached; by 1745, 2000 tons; 1808, 2616 tons; 1853, 4000 tons; 1860, 6959 tons—the *Victoria*, the last three-decker built in England; while the *Warrior*, the first ironclad built in Britain, and launched in 1861, was 9210 tons, in 1903 ironclads were building of 16,500 tons, and in 1919 of over 40,000 tons. We may observe by the way that up to the year 1860 the ships were practically the ships of the last two centuries—improved and developed largely, certainly, by the introduction of steam, of increased tonnage and of better lines, but still the same ships, and in the matter of armament with but little improvement to record over the beginning of the century. In 1786 the *Victory* was launched; she was at that time the largest three-decker in the English service; she is 186 feet long, has a tonnage of 2100 tons, and carried 100 guns, the bulk of which were long 32-pounders, weighing 56 cwt. In 1859 the flag-ship in the Mediterranean was the screw three-decker, the *Marlborough*; she was 282 feet long, 6100 tons, and carried 121 guns; her lower-deck guns were 65 cwt. 8-inch shell guns throwing a shell with bursting charge inclusive of 56 lb., while her remaining guns were the long 56 cwt. 32-pounders, with which the *Victory* had been armed nearly a century before. But since 1860 a vast revolution has been effected in our naval forces, and it seems almost incredible that in so short a space so great a transformation should have taken place. Masts and sails have disappeared, the wooden walls of Old England are things of the past, and, instead of the graceful frigate and stately line-of-battle ship, our battle-ships of the present day are floating castles protected with massive armour, crammed with engines, without which they could neither move nor fight their guns; elaborate provision for ventilation below is required; while the 32-pounders and 10-inch shell guns have given place to 70-ton rifled guns, throwing projectiles of 2000 lb. weight.

The use of steam as a propelling-power is the agent by which this change has been effected. From 1841 a gradual substitution of steam for sailing vessels began, which was not completed, however, until 1860; in fact, the last sailing-frigate in commission, the *Calypso*, only returned from the Pacific at the latter end of 1861. The first war steamers were all paddle-wheel vessels, and this mode of propulsion brought a change in the armament, or rather in the method of mounting guns. The paddle-wheels being quite exposed, and the machinery also being mostly above the water-line, there was great danger that a lucky shot would soon put a ship out of action, if compelled to fight broadside to broadside, as ships had been accustomed to do formerly. To obviate this danger as far as possible, the few guns these paddle-ships carried were mounted as pivot-guns, by which a far larger arc of training was possible than to a gun mounted on the broadside, thus enabling a ship to fight her guns without exposing her whole broadside to an enemy's fire. A few paddle-frigates, however, of large size, were built, and in their day did good service. Of these the well-known *Terrible*, nicknamed during the Russian war of 1854-56 the 'Black-Sea Cat,' was the largest; she was a ship of some 3600 tons, carried sixteen 68-pounders, and had engines of 800 horse-power. At the bombardment of Sebastopol the sailing line-of-battle ships were all towed into their places by the paddle-frigates, which were lashed on their off-sides. But it was the application of the screw as a means of propelling ships which has really revolutionised ships of war. Its vast superiority over the paddle was at once seen, and by the commencement of the Russian war in 1854 many ships of the line, frigates, and smaller vessels had been either converted or built as screw ships. After the conclusion of the war many of the sailing three-deckers were converted into steam two-deckers, being lengthened amidships, and engines being then fitted to them; while during the three or four succeeding years naval architecture seemed to have reached its acme, the line-of-battle ships and frigates which were launched at the time being quite unsurpassed for beauty of their hulls, their size, and their sailing and steaming qualities. Strangely enough, for the first time in history, the new ships at this time were far superior to the French, especially the line-of-battle ships, which all carried their lower-deck guns twice as high out of the water as the French ships, and were altogether finer and handsomer models. But the knell of wooden ships had already sounded, and many of the finest line-of-battle ships built at this time were never even commissioned.

To Napoleon III. belongs the idea of plating ships with iron. The effect of shells on the ships at the first bombardment of Sebastopol showed the necessity of some means of protection, and led to the laying down in France and England in 1855 of what were called floating batteries, plated with 4 inches of iron on 20 inches of wood backing; flat-bottomed and unmanageable, but carrying sixteen 68-pounders in their batteries. Three years later the first ironclad frigate was laid down at Tonlon, the *La Gloire*, built of wood and plated entirely with 4½-inch iron plates to 6 feet below the water-line; she was 250 feet long, with 55 feet beam, had a ram-bow, and could steam about 13·5 knots. In 1861 our *Warrior* was launched, built entirely of iron, but armour-plated for only two-thirds of her length, her bow and stern being unprotected; she had a displacement of 9210 tons, and was 420 feet over all, with a beam of 59 feet; her plating was 4½ inches thick, and her speed nearly 15 knots. She was quickly followed by ships in which the armour was carried completely round the hull; and several of the new line-of-battle ships were cut down, and

converted into armoured frigates with ram-bows, and with plating from 4½ to 6 inches in thickness. In 1861 the civil war between the Northern and Southern States of the American Union broke out, and the naval action fought in Hampton Roads on 9th March 1862 powerfully influenced the future lines of battle-ship construction. At the outbreak of hostilities the *Merrimac*, a large 50-gun steam-frigate, under repair at the Norfolk dockyard, was set on fire to prevent her from falling into the hands of the Confederates. She was, however, only partly burned, and the Confederates built up over her deck and down upon her sides to below the water-line a shot-proof covering formed of sloping plates of railroad iron, which met at the top like the roof of a house. Armed with two 100-pounder Armstrong guns and eight 11-inch guns, she on the 8th of March 1862 steamed out to attack the blockading Federal squadron, consisting of two sailing-frigates, the *Cumberland* and the *Congress*, both of which she sank. The next morning she met an antagonist which, although much smaller, proved more than

Fig. 2.—Turret-ship, *Royal Sovereign* of 1862.

a match for her—the famous *Monitor*, built by Ericsson (q.v.), parent of the monster turret-ships of the present day. She was only 210 feet long, with an extreme beam of 45 feet; her deck and low sides were plated, and she carried two 150-pounder Dahlgren guns in a single turret amidships, which was protected with eight 1-inch iron plates screwed together, and was turned by steam; she had no bulwarks, and her deck was barely two feet out of the water. The *Merrimac* had to retreat before her small opponent. A demand immediately arose in England for the construction of turret-ships, and Captain Cowper Coles (q.v.), who had long been pressing this type of ship on the Admiralty, now came forward with plans for converting some of the wooden ships into 'Monitors,' and as the result the *Royal Sovereign*, a new 131-gun ship, was cut down, armour-plated, and fitted with four turrets, each carrying two 9-ton guns. It was evident that for carrying heavy guns the turret system offered great advantages; but turret-ships did not immediately supersede broadside ships. Thus the *Bellerophon* (1866), designed by Sir E. Reed, was a broadside ship, with a complete water-line belt, and 5-inch armour over her main-deck battery, in which were mounted twelve 12-ton muzzle-loading rifled guns. Iron had now superseded wood in the construction of the hulls, a double bottom extended for some two-thirds the length of the ship, while by means of transverse and other bulkheads the whole hull below the water-line was subdivided into a number of watertight compartments. Two sets of engines, each driving a separate screw, one on each quarter of the ship, were also superseding the single screw.

Captain Coles was permitted by the Admiralty, under pressure from parliament, to design the *Captain*, a large ship of over 6000 tons, with a freeboard of only 6 feet, and heavily sparred so as to give her great sail-power. But at the Admiralty

her freeboard for a masted ship was considered dangerously low; and the Admiralty view was embodied in the *Monarch*, with a freeboard of 14 feet. Off Cape Finisterre, on the 6th of September 1870, the *Captain* capsized under sail in a heavy squall, and went down immediately with 500 officers and men, including her captain, Burgoyne, and Captain Coles himself.

In 1868 a committee reported that, to secure the full advantages of the turret system, it was necessary that vessels should have a low freeboard, no sail-power, and only one military mast. The result was the construction of the three sea-going turret-vessels, *Devastation*, *Thunderer*, and *Dreadnought*.

Fig. 3.—The *Devastation*.

Protection was afforded by a belt of 14-inch armour at the water-line; above this, for about half the length, was an armoured breastwork with 12-inch armour, which protected the base of the turrets, the turrets themselves having armour of the same thickness. These ships originally carried four 35-ton muzzle-loading rifled guns, but the *Devastation* (completed 1872) and *Thunderer* were re-armed with 29-ton 10-inch breech-loaders.

In 1875 were launched the *Alexandra* and *Téméraire*. In these and a few smaller ships the attempt was made to combine the advantages of the turret system with the broadside, so as to permit of an end-on fire from two or more of the heavy battery guns. Both the *Alexandra* and *Téméraire* carried 25-ton and 18-ton guns in their batteries; they both took part in the bombardment of Alexandria in 1882, and were only struck off the effective list in 1901.

The battle between guns and armour was now being waged more fiercely than ever. France and other Continental naval powers had long adopted rifled breech-loading guns; in 1879 the Admiralty decided for breech-loading guns; but it was not until 1881 that the manufacture of the new breech-loading ordnance fairly commenced. The increasing thickness of armour called for yet heavier guns; the adoption of the turret or barbette system had become inevitable; and Sir N. Barnaby designed the 'citadel' type of ship. In it the continuous armour-belt round the water-line was done away with, but armour of great thickness was concentrated round a citadel in the central portion of the ship, varying from about one-third the length of the ship to nearly a half, the armour extending to a depth of some 5 feet below the water and some 6 feet above. In the *Inflexible* the armour on the water-line was 24 inches thick, with 17 inches on the turrets. From the base of the citadel fore and aft extended the whole remaining length of the ship a watertight turtle-backed armoured deck, from 2½ to 3 inches thick; and below this deck, which was itself below the water-line and within the citadel, were contained

all the vital parts of the ship—engines, boilers, magazines. All round the water-line of the long, unarmoured ends of these ships above the armoured deck were constructed coffer-dams filled with cork. The idea was that the unarmoured ends might be destroyed by the enemy's fire, but that the body of the ship would remain intact—the citadel, in fact, resting upon an unsinkable inner ship below the surface of the water, which was divided into an immense number of different watertight compartments, in addition to the compartments of the double bottom. The *Agamemnon* and *Ajax*, somewhat smaller than the *Inflexible*, were built at the same time; none of these three ships steamed or steered well, and they were the last to carry muzzle-loading guns and to have iron armour. In the *Colossus* and *Edinburgh* (1881) their defensive powers were much increased by their being protected with 'compound' armour—iron armour faced with steel—while they were the first ships to carry the new 47-ton 12-inch breech-loading guns in their turrets.

To deal with torpedo-boats, it became necessary for the few heavy guns to be supplemented by a large number of light guns, and to this necessity we are indebted for all the small quick-firing guns now in use. It thus came about that, as a certain number of guns had to be mounted on the broadside, a material alteration in the design of the citadel ships became necessary, and six battle-ships of the 'Admiral' class were built. The distinguishing features of these ships were the mounting of the heavy guns in two 'barbettes,' one forward and one aft, with a central battery built between them, in which an auxiliary battery of 6-inch guns was mounted. It was claimed for the barbette system that the guns could be carried much higher out of water; they are revolved on a turn-table inside the barbette, the armour of which can be made sufficiently thick effectually to protect this movable platform, and thus prevent any chance of jamming, when, as in the case of turrets, the whole structure has to be revolved. In the earlier barbette ships, the whole gun being exposed except when in the loading position, the guns were much more liable to injury than when mounted in turrets; but since 1893 there are armoured hoods revolving with the guns.

The 'Admiral' class were not only deficient in armour protection, but the disposition of the armour was bad; on the other hand, their armament was a very formidable one. One, the *Benbow*, carried two breech-loading 111-ton guns, one in each barbette; while the *Collingwood*, which was somewhat smaller than her five sisters, carried four of the breech-loading 12-inch 47-ton guns. A belt of 18-inch compound armour protected about 150 feet of the water-lines of the ships amidships; at each end the armour was carried up to the upper-deck so as to form a wall protecting the loading arrangements of the barbette guns and the ammunition-supplies, while athwartships bulkheads complete the citadel; before and abaft the citadel was a 3-inch armoured deck. The weak points are the long unarmoured ends, the unprotected central batteries, and the fact that the bases of the barbettes are only partially protected. Yet they were formidable ships in their day; they were the first really homogeneous squadron built for the fleet, and although possessing but very low freeboards, they proved admirable sea-boats and excellent steamers. The ill-fated *Victoria* and her sister-ship the *Sans-Pareil* were single-turreted ships of 10,473 tons; in their turrets were mounted two of the unwieldy 111-ton breech-loading guns, while farther aft was a battery of twelve 6-inch guns, with a 10-inch gun as a stern-chaser, and the armour protection was as defective as in the 'Admiral' class. The *Victoria* was sunk off Tripoli, in the Levant, 22d June 1893.

by collision with the *Camperdown*, and foundered, with Admiral Tryon and 350 officers and men, a few minutes after being struck.

When, in 1885, Sir W. White was appointed Director of Naval Construction, he found our fleet composed of heterogeneous types, and our latest ships looked upon with the greatest distrust by the service—the two exceptions to the sweeping condemnation which naval officers had passed on Sir N. Barnaby's designs being the *Trafalgar* and *Nile*, laid down in 1886. The alarm at the small amount of armour on the ships of the 'Admiral' class, and its faulty distribution, was so great that when, in 1885, it was decided to build two new ships, it was determined that these should be improved 'Devastations' of 11,940 tons; they were protected by a

b, spar-deck with quick-firing guns; c, officers' quarters; d, men's quarters; e, barbettes, with four 67-ton guns mounted in pairs; f, fighting-top, with two 6-pounder quick-firing guns.

nearly complete water-line belt of compound armour 20 inches thick; above this belt was a citadel of 16-inch armour, which protected the bases of the turrets, which were themselves of 18-inch armour. The armament consisted of four 67-ton guns in the turrets, and a secondary battery of eight of the new quick-firing 4·7-inch guns in a casemate between the turrets, protected by 4-inch steel armour. Sir N. Barnaby protested strongly against the design of the new ships, for which he had to draw the plans; nor did they altogether meet with the approval of his successor, their great defect being their low freeboard. There was a feeling at the time of the launch of the *Trafalgar* that these two ships would be the last heavy armoured ships; even the *Times* voiced the impression that the days of armour for ships were numbered. Admiral Aube in France was also then preaching his crusade against heavy battle-ships, and advocating instead the system of 'corsair' warfare against our trade.

As the result of a press agitation in 1888 denouncing the weakness of the fleet, the government in 1889 brought in the Naval Defence Act, which provided for the construction of 10 first-class battle-ships, 40 first and second class cruisers, and 20 torpedo gunboats. The act marked the birth of our modern navy, and the completion of the building programme placed our navy in a far stronger position than it had occupied for many years.

Sir W. White was soon to show himself the greatest naval designer of his time, and the creator of the modern battle-ship. The units of a modern fleet fall into six classes—battle-ships, battle cruisers, light cruisers, torpedo-boat destroyers, submarines, sloops. It was now possible to build in classes, and thus introduce into the navy that homogeneity which had been up to that time so sadly lacking in our armoured ships. Of the ten new battle-ships it was determined that eight should be vessels of 14,150 tons, with engines of 13,000 indicated horse-power, which should give a speed of 17·5 knots. They were 380 feet long, with a beam of 75 feet and a draught of 27 feet 6 inches. Protection was afforded by a water-line belt of 18-inch compound armour for 250 feet of their length. Above this again, between the barbettes, was a belt of 5-inch steel carried up to the main-deck; at each end of the belt were 16-inch athwart-ships bulkheads, and at each end of the citadel thus

formed rose the barbettes, which were protected by 17-inch armour; before and abaft the armour-belt, protection was afforded by a 3-inch armour deck. The side of the ship was thus protected by a depth of 15 feet of armour, while the length of the unarmoured ends was reduced to proportions which would no longer endanger the stability of the ships in action should they be destroyed. The armament of the ships consisted of four 13·5-inch guns in pairs in the barbettes, except in the case of the *Hood* (which had turrets, not barbettes); ten 6-inch quick-firing guns, four of which were in 5-inch casemates on the main-deck, and the other six in shields on the upper-deck; sixteen 6-pounders and twelve 3-pounders, distributed over different parts of the ships, with three torpedo-tubes, two of which are submerged. The new 'Royal Sovereign' class were the prototypes of the modern battle-ships. At the same time the *Centurion* and *Barfleur*, of 10,500 tons displacement, were built for service on distant stations, and so as to pass easily through the Suez Canal; in design they were identical with the 'Royal Sovereign' class, but carried 10-inch guns in their barbettes, with less armour protection. The underlying idea in Sir W. White's designs was to produce a ship which, while she should have good sea-keeping qualities and good speed, should also be a steady gun-platform and carry her guns sufficiently high out of the water to be able to fight them even in moderately bad weather. To gain these qualities it was necessary to build ships of larger displacement, and to give them a high freeboard, so that they could steam against a head sea and yet fight the fore barbettes guns, which it was very often impossible to do in low-freeboard ships; and it was to gain an increased height for the guns that barbettes were now definitely adopted in place of turrets. A glance at the diagrams of the *Rodney* (fig. 4), one of the 'Admiral' class, and of the *Royal Sovereign* (fig. 5) respectively will show at once the great advance made in the way of protection.

On the completion of the Hamilton programme of 1889, a new one was brought forward in 1893 by Lord Spencer, and the result was the laying down of the nine ships of the 'Majestic' class, as it had now been settled that the normal strength of the navy must be maintained at a standard which would admit of its meeting successfully a combination of any other two powers. Their design was practically the same as the 'Royal Sovereigns'; but there were some notable improvements. Steel armour, 9 inches thick, hardened on the Harvey principle, was substituted for the 18-inch compound of the earlier ships, and there was thus a considerable saving of weight, while the resisting-power of the new armour was much greater. This saving in weight was used to protect that portion of the ship's side, some 250 feet in length and 15 feet in depth, which is covered with armour, with plating of a uniform thickness of 9 inches; the barbettes for the heavy guns were given 14-inch armour, while the barbettes guns, which were completely exposed in the 'Admiral' and 'Royal Sovereign' classes, were protected in the new ships with steel hoods, 10 inches thick, made of specially hardened steel; the secondary battery of twelve 6-inch quick-firing guns were all protected by 6-inch steel casemates, while the thickness of the protective deck, which was made to take the form of a turtle-back, curving down from just above the water-line in the central part of the ship to the lower shelf of the armour-belt, was increased to 4 inches, thus adding more than a third to the protection already afforded by the outer belt, while an additional 800 tons of coal were carried. An additional 750 tons was added to the displacement of the ships, which brought it up to 14,900 tons, as compared

with the 14,150 of the *Royal Sovereign* and her sisters. Another important change was the adoption as the heavy gun for our battle-ships of the wire-wound 12-inch gun, which throws a projectile of 850 lb. with a muzzle velocity of nearly 2500 feet a second; two aimed rounds could be fired from it per minute, while in penetrating-power it far exceeded the older and heavier guns it superseded. The 15-inch gun has been adopted by almost all the great naval powers as the standard weapon for the heavy armament of their battle-ships.

In 1896-97 another group of six ships, known as the 'Canopus' class, were laid down; they were of somewhat smaller tonnage (12,950) than the 'Royal Sovereigns' and the 'Majestics,' and drew less water by 18 inches than those ships, so that they would pass easily through the Suez Canal; the thickness of the side armour was reduced from 9 inches to 6, and to 12 inches on the barbettes instead of 14; but, on the other hand, a belt of 2-inch nickel-steel was carried forward from the fore end of the citadel to the stem and downwards to the ram, thus materially strengthening the fore-part of the

ship; the speed was also increased to 18 knots, and the coal-supply to 2300 tons. The armament was the same as in the ships of the 'Majestic' class.

Another group of eight ships of still more formidable character than any yet built were laid down in 1898-1901. These vessels are known as the 'London' class; their displacement was raised to 15,000 tons, and the speed to 18 knots. The thickness of the armour is 9 inches on the side, which is carried forward to within 30 feet of the bow, and from there to the ram there is a 3-inch belt of hard steel; the armour on the barbettes is 12 inches thick, and the whole of the armour is hardened by the Krupp process. The armament is the same as in the earlier classes, but the guns are improved. In three of the ships the disposition of the armour forward is somewhat different.

In the 'King Edward VII.' group of 1902, the displacement was raised to 16,350 tons; they had a length of 425 feet, with a beam of 78 feet, and a speed of 18.5 knots. In these ships the side armour between the barbettes is carried up to the level of the upper-deck, its

Fig. 5.—Diagram showing Disposition of Armour in Battle-ships of the 'Royal Sovereign' class (1889); 14,150 tons; 13,000 I.H.P.; speed, 17 knots. (From F. T. Jane's *All the World's Fighting Ships*.)

ARMAMENT.—(a) Four 13.5-inch 67-ton guns, two in each barrette; (b) ten 6-inch quick-firing guns in casemates, six on upper, four on main deck, with twenty-eight small quick-firing guns (6- and 8-pounders), and three torpedo-tubes.

thickness, however, between the levels of the main and upper decks being reduced to 7 inches. The offensive power was much increased by the addition of four 9.2-inch guns, carried singly in turrets protected by 7-inch armour on the upper-deck, one at each corner of the main-deck central battery, in which the secondary armament of 6-inch quick-firing guns is mounted, instead of in casemates. All the battle-ships from the 'Majestic' class onward have four submerged discharges for the 18-inch torpedoes. The three battle-ships of the 1903 programme were the last ships to be designed by Sir W. White, who was succeeded by Mr P. Watts in 1902. So far from the predictions of certain naval experts of 1887 coming true, that the *Trafalgar* would be the last battle-ship to be built for our navy, the position of the armoured battle-ship is firmer than ever. The result is that the newest ships designed for the navy are more powerful than ever, with thicker armour and heavier armament. The *Dreadnought*, with displacement of 18,000 tons, was the next class in 1906. These have increased in size each successive programme until in the 'Queen Elizabeth' type we have reached 27,500 tons displacement, 25 knots speed, eight 15-inch breech-loading guns, as compared with ten 12-inch guns, twenty-seven 12-pounder guns, and five torpedo-tubes; the speed being 21 knots, with an indicated horse-power of 16,750. To appreciate the great advance made in our battle-ships during the time Sir Philip Watts was in office, and Sir

Tennyson D'Eyncourt, who succeeded him, compare the *King Edward VII.* with the *Queen Elizabeth*. By 1914, when war broke out, the Grand Fleet consisted of 28 battle-ships of 'Dreadnought' class; three of these were building for foreign powers.

The battle cruisers of 'Dreadnought' class were introduced in 1908 with *Invincible* and *Inflexible*, of 17,250 tons and 26 knots speed, and eight 12-inch guns. These have now been increased in size to 33,000 tons, 32 knots, and six 15-inch guns. These battle cruisers bore the brunt of the fighting, and of them *Queen Mary* and *Invincible* were sunk at the battle of Jutland, and *Inflexible* and *Indefatigable* badly damaged at the Dardanelles. These superseded the armoured cruisers described below, and rendered scouting with light cruisers a very difficult matter to the enemy.

'Cruisers' is a term which was wont to include all ships not ranked as fighting ships of the line, and was applied indiscriminately to frigates, corvettes, sloops, and even such small vessels as armed cutters. To these have been added torpedo-boat destroyers and submarines. All may be called the eyes of the fleet—submarines especially were used to collect and transmit news of movements of enemy surface craft and aircraft near enemy's coast during the Great War. The modern cruiser has developed as masts and sails have disappeared, and speed has become more and more essential. Under this head are now included the monster 14,000-ton armoured cruiser and the little 2000-ton rapid scouts, which

are the latest and smallest development of the fast cruiser. 'Armoured' cruisers are vessels with some description of armoured belt, while 'protected' vessels have only an armoured protective deck. The first batch of armoured (then called 'belted') cruisers were the *Orlando* and her six sisters, laid down in 1885. With a displacement of only 5600 tons, and comparatively short, they yet had a speed of 18 knots or over. They were protected by a water-line armoured belt, 10 inches thick and 5 feet 6 inches broad, shut in at each end by 16-inch transverse bulkheads; extending fore and aft at each end of this belt was a protective belt of 3-inch steel. The armament consisted of two 9·2-inch guns and ten 6-inch quick-firing guns, besides smaller guns. Their great defect was that when they were fully loaded the top of the belt was down to the level of the water, their guns were unprotected, and their coal-supply limited. It was under the Naval Defence Act of 1889 that the development of the modern cruiser really began. Here, as with the battle-ships, Sir W. White built in groups, 9 first-class cruisers, known as the 'Edgar' type,

and 28 second-class cruisers being laid down. Of the second-class cruisers 20 were vessels of 3600 tons displacement, with a speed of 19·5 knots, which was exceeded by half a knot in many of the vessels; their armament consisted of two 6-inch quick-firing guns, one forward and one aft, and six 4·7-inch quick-firing guns on the broadside, with eight 6-pounders and some machine-guns; and there was a steel protective deck of from 1 to 2 inches in thickness. The remaining eight, known as the 'Astræa' class, were somewhat larger, their displacement being 4360 tons, and the speed was the same, but the coal-supply was nearly doubled, being raised from 550 tons to 1000, while two additional 4·7-inch guns were added. Since 1889 three further groups of second-class cruisers have been built; nine of the 'Talbot' class, laid down in 1893-94-95, are improved 'Astræas,' vessels of 5600 tons, of the same speed but a much-improved armament—five 6-inch quick-firing guns and six 4·7-inch, with nine 12-pounders and some smaller guns; in all these ships 6-inch guns have been substituted for the 4·7-inch. Next, in 1896, came the four

Fig. 6.—Diagram showing Disposition of Armour in the new Battle-ships of the 'King Edward VII' class (1902); 16,350 tons; 18,000 I.H.P.; speed, 18·5 knots. (From F. T. Jane's *All the World's Fighting Ships*.)

ARMAMENT.—(a) Four 12-inch 50-ton wire guns, two in each barbette; (b) four 9·2-inch guns, singly in turrets, two each side as shown; ten 6-inch quick-firing guns, in central battery, five each side, with twenty-eight small quick-firing guns (12- and 3-pounders), and four submerged torpedo-tubes.

cruisers of the 'Arrogant' type; they are of much the same dimensions as the 'Talbot' class, but are designed to act as rams. Finally, there is a group of five, the first three of which, the *Hyacinth* and two sisters, were laid down in 1896; and the two last, the *Encounter* and *Challenger*, in 1901. The second-class cruiser is a thing of the past, but they did good work in distant seas during the Great War. No more vessels of medium size of this description called 'light' cruisers are being built.

The nine first-class cruisers of the 'Edgar' class were among the most successful creations of Sir W. White. Of 7700 tons displacement, with a nominal speed of 19·5 knots, these fine ships in every case when commissioned for service proved in reality to have a speed of between 20 and 21 knots, which they were able to keep up, in ordinary circumstances of wind and weather, as long as their coal lasted. As armament they carried two 9·2-inch guns, one forward and one aft, and twelve 6-inch quick-firing guns, with some twenty smaller guns. Four of the 6-inch guns are in 6-inch casemates on the main-deck, the remaining guns on the upper-deck with shields. Protection is afforded by a turtle-back armoured deck, 5 inches thick on the slopes and 1 inch on the flat surface, while the coamings are also protected by 6-inch armour. The *Powerful* and *Terrible* were laid down in 1895, and commissioned in 1897. They are vessels of 14,200 tons displacement, with a speed of 22 knots, protection

being afforded by a turtle-back armoured deck of Harvey steel, 6 inches on the slopes and 3 inches on the flat surface. Their armament consisted of two 9·2-inch guns, mounted in barbettes, the bases protected by 6-inch Harvey steel, one forward and one aft, protected by 6-inch shields; sixteen 6-inch quick-firing guns, eight on the main and eight on the upper deck, in 6-inch casemates; and sixteen 12-pounders and fourteen smaller quick-firing guns, with four submerged torpedo-tubes. They were the first vessels to be fitted with the Belleville water-tube boiler. These ships were built as a reply to two large belted cruisers built by Russia as a reply to our 'Edgars.' In 1895-97 eight protected cruisers were laid down, known as the 'Diadem' class; they are smaller than the *Powerful* and *Terrible* by 3000 tons, and both their protection and armament are less, but their general design is identical. They were the last of their class, and are now used as depot hulks.

The armoured cruiser is the large cruiser of the future. In 1898 the Admiralty at last recognised that our large protected cruisers would be at a serious disadvantage if called upon to engage the improved armoured cruisers which the French were building, so in 1898-99 ten armoured cruisers were laid down. Four of these, known as the 'Drake' class, were the largest armoured cruisers afloat; they had a displacement of 14,100 tons, with engines developing 30,000 indicated horse-power,

giving them a speed of 23 knots. They have realised a speed of nearly 24 knots, and they can steam 4300 miles at 19 knots, or at 11 knots from Spithead to Hong-kong, without coaling. They are protected by a 6-inch belt of hard Krupp steel between the barbettes, which is carried up to the height of the main-deck, while from the fore barrette on up to the height of the upper-deck this belt tapers to 2 inches (see diagram). There is a protective deck, 3 inches on the slope and 2 inches on the flat, with an 8-inch transverse bulkhead aft. The armament consists of two 9.2-inch guns in barbettes, one forward and one aft, protected by 6-inch armour; sixteen 6-inch quick-firing guns in 6-inch casemates, with fourteen 12-pounders and some smaller guns, and two submerged torpedo-tubes. These formidable vessels were really second-class battle-ships in disguise, and were certainly more than a match for many of the older battle-ships. The remaining six, known as the 'Cressy' class, were somewhat smaller, with a displacement of 12,000 tons and a speed of only 21 knots; their armour protection and armament are much the

same as in the 'Drake' class. Since 1900 sixteen armoured cruisers of a somewhat smaller type, known as the 'County' type, have been laid down. They all have a speed of 23 knots; but while the first ten have a displacement of 9800 tons, the remaining six have a displacement of 10,700, which has enabled increased armour protection to be given them. Thus, instead of a partial water-line belt only 4 inches thick, the later vessels have a complete belt, with a maximum thickness of 6 inches, tapering to 2 inches forward; while, instead of an armament of sixteen 6-inch guns, they have two 7.5-inch quick-firing guns (a quite new type of gun) and ten 6-inch quick-firing guns, in addition to ten 12-pounders, which both types have, and some fifteen smaller guns. In 1903 were laid down six armoured cruisers of a new class, with a displacement of 13,550 tons and a speed of 22.5 knots, protection being afforded by a 6-inch water-line belt, tapering at ends to 4 and 3 inches; above that again a central citadel some 300 feet in length, protected also by 6-inch armour, shut in at the ends by 6-inch bulkheads. The armament, a formid-

Fig. 7.—Diagram showing Disposition of Armour in first-class Armoured Cruiser of the 'Drake' class (1901); 14,100 tons; 30,000 I.H.P.; speed, 23 knots. (From F. T. Jane's *All the World's Fighting Ships*.)

ARMAMENT.—(a) Two 9.2-inch guns, singly in barbettes; (b) sixteen 6-inch quick-firing guns, in eight double casemates, four each side, with fourteen 12-pounder quick-firing guns, and two submerged torpedo-tubes.

able one, consisted of six 9.2-inch guns, one forward and one aft, and one at each corner of the citadel, with ten 6-inch guns in the central battery, and twenty-eight small and machine guns.

The battle cruiser takes the place of the first and second class protected cruisers. Any ground we may have lost by delaying the construction of this class of vessel until 1899 has now been fully made up, and Britain is now far ahead of any foreign country in this type of cruiser. But a class called 'Light' cruisers has been introduced to supersede the second-class and third-class cruisers. These resemble big torpedo-boat destroyers. They commenced with the 'Bristol' class, 1910, of 4800 tons, 27 knots, two 6-inch and ten 4-inch guns, and have increased to about 6000 tons, 28 knots, and five 6-inch guns in centre-line, the 'Caradoc' class; and several of the old second-class cruisers, the 'Latona' type, were fitted and used for mine-laying.

The duties of cruisers are: (1) to act as scouts for the battle fleet, keeping in touch with the enemy and communicating his movements; (2) to keep up communication between the battle fleet and its base or bases; (3) to hunt down any hostile cruiser known to have escaped from an enemy's port, and not to rest until she has been brought to action and destroyed; (4) to patrol the principal trade-routes. It was at one time believed that these duties would be best performed by a number of medium-sized cruisers, such as those built under the first Naval Defence Act; but with the advent of the armoured cruiser in foreign navies, it became clear that one fast, well-armed,

and armoured cruiser might easily sweep away and destroy in detail any number of protected cruisers. Hence the large number of armoured cruisers that have recently been added to the fighting strength of our own and other navies.

Battle-ships and cruisers alike are lit by electricity, by means of which also the guns are fired and torpedoes discharged; they are also provided with powerful electric searchlights, which illumine the sea for some two miles, while night-signalling and day-signalling is also carried on by electric light. As a further protection against torpedoes, all large ships were provided with torpedo-nets of steel wire, which were rigged out all round the ship by means of booms about 30 feet from the ship's side. When not required these nets were stored inboard. But torpedo-nets and booms have been entirely abolished, and their place has been taken by bulges built on to the sides of battle-ships; this causes the torpedo to explode outside the real hull, and the speed is only reduced by about 1 knot at full speed, and by smaller amounts at low speeds.

Another protection against mines for men-of-war and merchant-ships during the war was a kind of otter, resembling a fish. The otters were towed from the forefoot of the ships and swam below the surface, and about 60 feet or more from the ship the mine-moorings were caught by the wires and slid along to the fish, where a knife cut them, and they floated clear. These were called Paravanes.

Torpedo-boats date from 1877, as a consequence of the introduction of the Whitehead or 'fish' Torpedo (q.v.). From the first the British Ad-

miralty looked with disfavour upon the torpedo-boat, although between 1877 and 1891 a considerable number were constructed; they were considered to be a weapon *par excellence* for weak powers, and as more suited for defensive than offensive purposes. Foreign navies adopted them largely, and in France there was a scheme for sweeping the Channel, in the event of war, by means of swarms of torpedo-boats. In 1892 this menace was so formidable that the Admiralty resolved to take special measures against them. The result was the Torpedo-boat Destroyer. There are practically two classes of torpedo-boats in France: the first-class torpedo-boat for coast and harbour defence, vessels of about 85 tons and a speed of 24 knots; and the so-called 'torpilleurs de haute mer' or 'squadron' torpedo-boats, which have a displacement of 150 tons and a nominal speed of 26 knots. Neither of these types can be counted on as good for much, except in calm weather. The first destroyers designed by the Admiralty were vessels of from 250 to 300 tons displacement, with a speed of 27.5 knots; they carried for armament one 12-pounder quick-firing

gun forward, and five 6-pounders, besides two torpedo-tubes. They proved to be excellent sea-boats. By 1898 we had over eighty destroyers constructed or building, and in 1903 we had over 150 of these formidable little vessels. The displacement was gradually increased to 500 tons, and many of them attained a speed of 30 knots; their armament remained the same, the increased tonnage being absorbed by more powerful engines and an increased coal-supply. But in 1910 the size was increased to 1000 tons, speed 34 knots, and armament two 4-inch guns; while during the war they increased to over 1300 tons, speed 37 knots, and four 4.7-inch guns in centre-line, and two triple torpedo-tubes. Since 1899 France, Russia, and Germany had been following in our steps, but we had fortunately a long start with our formidable fleet of destroyers; but at the outbreak of the Great War Germany was actually in numerical superiority, and produced most excellent types called V., S., and G. There were several actions between our torpedo-boat destroyers and the Germans, but the British torpedo-boat destroyers practically always defeated

Fig. 8.—H.M.S. *Queen Elizabeth*. (Reproduced by permission of Messrs Sampson Low, Marston, & Co., Ltd., from the naval annual, *Jane's Fighting Ships*, 1919.)

ARMAMENT.—Eight 15-inch guns, twelve 6-inch guns, two 3-inch guns (anti-aircraft), four 3-pounders, five machine-guns; four submerged (broadside) torpedo-tubes, 21 inches. Normal displacement, 27,500 tons; full load, 31,300 to 33,000 tons; length between perpendiculars, 600 feet; length over all, 643½ feet; beam, 90½ feet; mean draught, 30½ feet; maximum draught, 33½ feet; complement, 1000 (approximately).

the German torpedo-boat destroyers. Destroyers can be used for the purposes of torpedo attack against battle-ships; but this sort of warfare can only be successfully attempted at night-time, or during a general action with the use of a smoke-screen. These smoke-screens were perfected and used with effect on several occasions, such as Jutland, Zeebrugge, Ostend, and minor actions in the Strait of Dover. The primary duty of destroyers is to accompany the battle fleets, over which they should keep continuous guard, in order to ward off the enemy's destroyers, torpedo-boats, and submarines.

Submarine boats are dealt with in the article SUBMARINE NAVIGATION. Here we need only say that the French were the first to make submarines of real value. The *Gymnote* of 1888 was the first; by 1904 France had built or was building nearly 50 submarines or submersibles, with displacements varying from 68 to 200 tons. Some have now increased to about 2000 tons displacement when submerged, and a few carry one heavy gun each—and may be forerunners of submersible battle fleets. Submarines proper either navigate below the surface of the sea or, when immersed to their proper bearings, are almost entirely covered by water. The 'submersible' besides navigating on the surface, has the power of submerging itself when required.

In 1905 the British navy was completely re-organised with the object of concentrating a strong striking force ready for immediate use in European waters. The non-fighting ships were withdrawn from distant stations, certain distant squadrons were reduced, and the North Pacific and South Atlantic squadrons were abolished. About 124 ships were struck off the effective list, including 13 battle-ships, 15 large cruisers, 42 smaller vessels,

and a number of other obsolete ships of all kinds, leaving the 'war-list' composed of effective fighting-ships only. The officers and men withdrawn by these changes were utilised as nucleus crews for a strong reserve of fighting-ships on the 'war-list,' whose crews could be completed and be ready for sea at very short notice. The 'war-list' of the navy at the beginning of 1905 consisted of 52 battle-ships, 36 armoured cruisers, 11 first-class unarmoured cruisers, 38 second-class cruisers, 21 third-class cruisers, with gunboats, torpedo destroyers, torpedo-boats, and submarines.

During the Great War the British fleet was distributed as follows:

Grand Fleet, comprising 'Dreadnought' battle-ships, battle cruisers, light cruisers, torpedo-boat destroyers, submarines, and auxiliaries, mainly at Scapa Flow, Orkneys; but part was generally at Rosyth, Firth of Forth.

Mediterranean.—'King Edward' and 'London' class battle-ships and the *Lord Nelson* and *Agamemnon*, some light cruisers, older torpedo-boat destroyers working in co-operation with the French and Italians. The French admiral, commander-in-chief, was at Malta, and had general charge of sea-forces in the Mediterranean, but there were special zones of action for each nationality.

Auxiliary Patrol.—This was a new force organised for anti-submarine work; it began with yachts, trawlers, drifters, and old torpedo-boat destroyers and torpedo-boats, supplemented later by sloops—'P' boats—looking like submarines on the surface, but really torpedo-boat destroyers.

Many ocean liners were converted into cruisers carrying 6-inch guns. These did excellent service on blockade duty and in convoy-work, and in freeing

the seas of similar enemy vessels, and two were fitted out as aircraft carriers.

By a time-honoured distinction, the executive or military branch of the *personnel* comprised all officers from the Admiral of the Fleet down to naval cadets, as well as warrant officers; to the civilian branch belonged engineer officers, doctors, accountant officers, chaplains, and naval instructors (the marines forming a category by themselves). Modern conditions have necessitated a change in the training of both officers and men; and engineer officers had become dissatisfied with their position as non-executive, in view of the growing importance of their duties and the largely increased number of the engine-room staff. By a new order brought out at the end of 1918 all officers for the executive and engineering and civilian branches were made executive officers, and given executive titles preceded by the name of branch to which they belong—e.g. Surgeon-commander, Paymaster-lieutenant, Engineer-lieutenant, &c. Cadets on joining are sent to the Naval College at Dartmouth for two years, and then to sea for three years; after which, as acting sub-lieutenants, they pass through a course at the college at Greenwich, followed by courses of gunnery, torpedo-work, and engineering. On passing they will be distributed between the executive and engineer branches, being as far as possible allowed to choose their branch. Sub-lieutenants of the executive will then go to sea for two years, and so become eligible for promotion to lieutenant. Engineer officers go through a special course at Keyham, and become eligible for promotion to lieutenant, whence they may rise to rear-admiral, uniform and titles being as in the executive. Cadets are also entered at seventeen to eighteen direct from public schools, and after a year's training—six months' if the cadet is at sea in a cruiser—they go to ships of the fleet and are amalgamated with the others. This system is under trial.

Recruiting is purely voluntary, and the term of engagement is twelve years, voluntary re-engagement for ten years qualifying for pension. The Royal Naval Reserve is drawn from the mercantile marine and fishing population of the country. The Royal Fleet Reserve, introduced in 1901, is designed to secure in war-time the services of men who have left the fleet after expiry of the ordinary twelve years' term. There are, besides pensioners, officers and seamen under fifty-five years of age who were not enrolled in the reserve, but are bound to serve in case of need. The Naval Forces Act of 1903 strengthens the reserve by authorising short service on condition that a term of seven years is completed in the reserve; and an act of 1902 authorised the formation of a body of Royal Naval Volunteers.

In 1914, at commencement of the war, the *personnel* consisted of: Naval officers, 9561; Naval ratings—seamen, engine-room, and others, 115,232; Marines—officers 595, men 17,646; Coastguards, 3013; Reserve—retired officers 866, pensioners 9110; R.N.R. officers 1660, men 16,341; R.N.R. trawler section, 1025; Fleet reserve, 29,033; R.N.V.R.—officers 199, men 5608. When the armistice was declared these numbers were:

Active service—Naval officers	13,678
Naval ratings—seamen, engine-room, and others	198,465
Royal Marine officers	1,527
" " men	47,533
	261,203
Coastguard	4,281
Reserves—Retired officers	1,145
Pensioners	9,918
R.F.R.	19,180
R.N.R. officers	7,523
" men	17,921
" " trawler section	37,145
R.N.V.R. officers	4,568
" men	44,432
	141,832
Grand total	407,816

The Royal Dockyards of Britain and those of other countries are the subject of a separate article; at COALING STATIONS will be found some discussion of those indispensable aids to naval effectiveness, with their later development oiling-stations. The growth of naval interests may be somewhat strikingly illustrated by contrasting the total naval estimates for the year 1885-86 with those for 1902-3 and for 1904-5; in the former year the total was £12,176,500, in 1902-3 it was £31,170,000, and 1904-5 it had increased to £36,889,000. In 1913-14 they were £51,250,000, and during the war went to £150,000,000.

During the Great War British naval losses were as follows: Total tons, 550,000, consisting of 13 battle-ships, 3 battle cruisers, 15 cruisers, 14 light cruisers, 8 monitors, 20 sloops, 26 mine-sweepers, 5 torpedo gunboats, 69 torpedo-boat destroyers and flotilla leaders, 58 submarines, 81 auxiliaries. Killed—officers 2061, men 20,197; wounded—officers 813, men 4035; missing—officers 15, men 8. The German fleet, consisting of 11 battle-ships, 5 battle cruisers, 6 light cruisers, 2 mine-laying cruisers, 51 torpedo-boat destroyers, surrendered to the Grand Fleet at sea, off the Firth of Forth, on 21st November 1918, and was then anchored in Scapa Flow with German care and maintenance crews; but on 21st June 1919 the German admiral, Von Reuter, sank them at their anchorage. At the end of 1919 the British naval force was reduced to Atlantic Fleet, consisting of 9 battle-ships, 5 battle cruisers, 8 light cruisers, 72 torpedo-boat destroyers, 49 submarines, 20 auxiliary craft in full commission; a Reserve Fleet, consisting of 6 battle-ships, 3 battle cruisers, 8 light cruisers, 40 torpedo-boat destroyers, 10 submarines, 40 auxiliary craft, with about one-tenth crews to keep all machinery efficient, and various ships on foreign stations with full crews—Mediterranean, China, North Atlantic, South Atlantic, North Pacific, South Pacific, Cape station, &c.—consisting of 8 battle-ships and battle-cruisers, 25 light cruisers, 35 torpedo-boat destroyers, and various small craft.

See W. James's *Naval History of Great Britain* (3d. ed. 6 vols. 1847); Lord Brassey, *The British Navy* (5 vols. 1882-83), and his *Naval Annual*; works by Admiral Colomb (1893) and Mr Spenser Wilkinson; Admiral Mahan, *The Influence of Sea Power upon History* (1890), *The Sea Power of Great Britain, The Interest of the United States in Sea Power, Types of Naval Officers*, and other works (1892-1912); Sir W. L. Clowes, *The Royal Navy, a History from the Earliest Times to the Present* (7 vols. 1897-1903), and other works; Sir Julian S. Corbett's *Drake and the Tudor Navy* (1900), *The Successors of Drake* (1901), and *Naval History of the Great War*; Sir J. K. Laughton, *From Howard to Nelson* (1899), and other works; Viscount Jellicoe, *The Grand Fleet, 1914-1917*; *Jane's Fighting Ships* (1919). Nawanagar, or JAMNAGAR, a seaport of India, and capital of a state (area, 3800 sq. m.; pop. 345,000), stands on the south shore of the Gulf of Cutch, 310 miles NW. of Bombay. Pop. 42,500.

Naworth Castle. See LANERCOST.

Naxos, the largest, most beautiful, and most fertile of the Cyclades, is situated in the Ægean, midway between the coasts of Greece and Asia.

Minor. It is 20 miles in length. The shores are steep, and the island is traversed by a ridge rising in Dia to 3289 feet. The wine of Naxos was famous in ancient as it is in modern times, and on this account the island was celebrated in the legends of Dionysus, and especially in those relating to Ariadne (q.v.). Its emery also has long enjoyed repute. It was ravaged by the Persians, 490 B.C., and after the conquest of Constantinople by the Latins became the seat of a dukedom founded by the Venetians. It was Turkish from 1566 till Greece became a kingdom. Naxos, the capital, is the seat of a Greek bishop and a Latin archbishop. See Tozer's *Islands of the Ægean* (1890).

Nazarenes. See EBIONITES.

Nazareth, the home of Jesus, anciently in the district of Galilee, 21 miles SE. of Acre, is still a small but flourishing town of Palestine. It lies in a hilly tract of country, and is built partly on the sides of some rocky ridges. In the earliest ages of Christianity Nazareth (which is not mentioned in the Old Testament) was quite overlooked by the church; the first Christian pilgrimage to it took place in the 6th century. The principal building is the Latin convent, on the supposed scene of the Annunciation; but the Greeks have also erected on another spot a church in commemoration. The traveller is also shown a Latin chapel, affirmed to be built over the 'workshop of Joseph'; the chapel of 'The Table of Christ' (*Mensa Christi*), a vaulted chamber, containing the veritable table at which our Lord and his disciples ate; and the synagogue out of which he was thrust by his townsmen. The Virgin's Well is just outside the town. The women of the village have long been famous for their beauty. Population, 7400.

Nazarites (properly *Nazirites*, from Heb. *nazar*, 'to separate'), men or women among the Jews who had consecrated themselves to God by certain acts of abstinence, as refraining from using wine, from shaving their heads, as well as from the defilement of contact with the dead. The law in regard to them is laid down in the Book of Numbers (vi. 1-21). The usual term of the vow was thirty days, but examples of vows for life were the cases of Samson, Samuel, and John the Baptist.

Nazianzen. See GREGORY.

Neagh, LOUGH, the largest lake of the British Islands, is situated in the province of Ulster, Ireland, and is surrounded by the counties of Armagh, Tyrone, Londonderry, Antrim, and Down. It is 16 miles in length and 10 miles in average breadth, contains 98,255 acres, is 102 feet in greatest depth, and is 48 feet above sea-level. It receives the waters of numerous streams, of which the principal are the Upper Bann, the Blackwater, and the Callan; and its surplus waters are carried off northward to the North Channel by the Lower Bann. Communication by means of canals subsists between the Lough and Belfast, Newry, and the Tyrone coalfield. The southern shores of the Lough are low and marshy, and dreary in appearance. It is well stocked with fish—lake trout, char, and pellen.

Neal, DANIEL, author of the *History of the Puritans*, was born in London, December 14, 1678. He was educated first at Merchant Taylors' School, and afterwards at Utrecht and Leyden, and in 1706 became minister of an Independent congregation in Aldersgate Street, London. His first work was a *History of New England* (1720), which met with a very favourable reception in America. But his reputation rests on his laborious and accurate *History of the Puritans* (4 vols. 1732-38; new ed., with Life by Joseph Toulmin, Bath, 1793). Neal died at Bath, 4th April 1743.

Neal, JOHN, American author, was born at Falmouth (now Portland, Maine), August 25, 1793. In his youth he was a Quaker, and he began the world at twelve as a shop-boy. In 1816 he failed in business, and turned to the study of law, supporting himself the while by his pen. He was one of the first Americans to write in the greater English magazines, and from 1823 till 1827 he lived in England, part of the time as one of Bentham's students and secretaries. After his return to America he settled in his native town, practised law, edited newspapers, lectured, and found relaxation in practising and teaching boxing, fencing, and gymnastics. He died 21st June 1876. Among his numerous works are a series of novels, *Bentham's Morals and Legislation*, and *Wandering Recollections of a Somewhat Busy Life* (1869).

Neale, JOHN MASON, hymnologist, born in London, January 24, 1818, was educated at Trinity College, Cambridge, became incumbent of Crawley, Sussex, in 1842, and in May 1846 warden of Sackville College, East Grinstead, where he died, August 6, 1866. He belonged to the most advanced section of the High Church party, and was long one of the most misunderstood and unpopular men in England. He was inhibited by his bishop for fourteen years, and burned in effigy in 1857, while throughout life his means were of the smallest. He founded in 1854 the well-known sisterhood of St Margaret. His most important work is his *History of the Holy Eastern Church* (4 vols. 1847-51); others were *Medieval Preachers* (1857), *History of the so-called 'Jansenist' Church of Holland* (1858), a preposterous adaptation of *The Pilgrims' Progress* (1853), and a long series of stories for the young, intended to popularise church history, but the value of which is almost exclusively other than historical. But his greatest work was his invaluable contribution to hymnology, both original and translated. His *Hymns for the Sick and Hymns for Children* were followed by his more important volumes of translations: *Medieval Hymns and Sequences* (1851), the *Rhythm of Bernard of Morlaix* (1858), and his *Hymns of the Eastern Church* (1863). His *Collected Hymns, Sequences, and Carols* appeared in 1914. See HYMN; his Life by Mrs Towle (1906); and his Letters (1910).

Neander, JOHANN AUGUST WILHELM, the greatest of church historians, was born at Göttingen, 17th January 1789, of Jewish parentage. His name prior to baptism was David Mendel, and by the mother's side he was related to the philosopher Mendelssohn. He received his early education at the Johanneum in Hamburg, and had for companions Varnhagen von Ense and Chamisso the poet. Even while he was a boy Plato and Plutarch were his favourite books, and he was profoundly stirred by Schleiermacher's famous *Reden über die Religion* (1799). Finally in 1806 he publicly renounced Judaism, and was baptised, adopting the name of Neander ('new man'), and taking his Christian names from several of his friends. His sisters and brothers, and later his mother also, followed his example. He now proceeded to Halle, where he studied theology under Schleiermacher, and concluded his academic course at Göttingen. In 1811 he took up his residence at Heidelberg as a *privat-docent*; in 1812 he was appointed extra-ordinary professor of Theology there; and in the following year he was called to the newly-established university of Berlin as professor of Church History. There he laboured till his death, 14th July 1850. Students flocked to him not only from all parts of Germany, but from the most distant Protestant countries. And his sweetness of character was no less attractive than his genius. Profoundly devotional, sympathetic, glad-hearted,

profusely benevolent, and without a shadow of selfishness, he inspired universal reverence, and was himself by the simplicity and sanctity of his life a more powerful argument on behalf of Christianity than even his writings. He used to give the poorer students free admission to his lectures, and to supply them with clothes and money. The greater portion of what he made by his books he bestowed upon missionary, Bible, and other societies, and upon hospitals.

Neander is believed to have contributed more than any other single Christian scholar to the overthrow, on the one side, of that anti-historical Rationalism, and on the other of that dead Lutheran formalism, from both of which the religious life of Germany had so long suffered. To the delineation of the development of historical Christianity he brought a generous and sympathetic, yet broad and impartial intellect. To him Christianity was a permeating force more than a series of dogmas, and the history of the church was throughout but the history of the divine life of Christ pervading humanity, to be understood only in proportion to the student's personal experience of the significance of the life of Christ. This is the meaning of Neander's famous aphorism—'Pectus est quod facit theologum.' The most striking characteristic of his great work is its objectivity in the portrayal of persons and the movement of events; its greatest merit is the admirable biographical skill with which the figures are made to pass before the reader; its one defect, the weakness with which the outstanding separate figures are fitted into their relation to the general movement of the history.

Neander's works, in the order of time, are monographs on Julian and his times (1812), St Bernard (1813), the Gnostics (1818), St Chrysostom (1822); *Denkwürdigkeiten aus der Geschichte des Christenthums und des Christlichen Lebens* (1822; 3d ed. 1845-46); *Antignosticus* (1826); the great *Allgemeine Geschichte der Christlichen Religion und Kirche* (6 vols. 1825-52); *Geschichte der Pflanzung und Leitung der Kirche durch die Apostel* (2 vols. 1833; 4th ed. 1847); *Das Leben Jesu Christi*, written as a reply to Strauss's work (1837; 5th ed. 1853); *Wissenschaftliche Abhandlungen* (1851); *Geschichte der Christlichen Dogmen* (1856). Most of these works are accessible in good English translations. See the studies by Hagenbach (1851), Otto Kraabe (1852), J. L. Jacobi (1882), Adelbert Wiegand, with a good bibliography (1889), and Schneider (1894).

Neanderthal, a wilder romantic valley between Düsseldorf and Elberfeld in Rheinland. In a limestone cave in this valley were found in 1856 some bones of a prehistoric man, and the peculiar formation of the skull induced anthropologists to regard it as typical of a separate race of ancient man—not the ancestor of modern man. Some explained the abnormality as pathological, but remains of the race have since been found elsewhere. To *Homo neanderthalensis* is assigned the Mousterian culture. See ANTHROPOLOGY.

Nea Pesara. See ERETRIA.

Neap-tides. See TIDES.

Nearchus, an officer of Alexander the Great, was a native of Crete, who settled in Amphipolis during the reign of Philip, and became the companion and friend of the young prince Alexander. In 330 B.C. he was governor of Lycia and other provinces in Asia Minor. In 329 he joined Alexander in Bactria with a body of Greek mercenaries, and took part in the Indian campaigns. Having built a fleet on the Hydaspes, Alexander gave Nearchus the command of it. He left the Indus towards the end of November 325, and, skirting the coast all the way, arrived at Susa, in Persia, in February 324. His own narrative of his voyage has been preserved in the *Indica* of Arrian.

Nearctic. See GEOGRAPHICAL DISTRIBUTION.

Neath, a municipal borough and river-port of Glamorgan, South Wales, on a navigable river of the same name, 8 miles ENE. of Swansea by rail. It stands on the site of the Roman station *Nidum*; there are remains of an ancient castle, burned in 1231, and near it are the ruins of Neath Abbey, described by Leland as 'the fairest abbey in all Wales,' but now sadly decayed and begrimed by smoke and coal-dust. Till 1918 one of the Swansea boroughs, Neath has extensive tin-plate works, steel and iron foundries, &c., and chemicals are manufactured. The engineering-works are also important. Pop. (1851) 5831; (1881) 10,447; (1921) 18,936, almost doubled in 1922 by absorption of Briton Ferry, &c.

Neat's-foot Oil is, as the name implies, an oil obtained from the feet of the common ox, either by splitting them up and boiling them over an open fire, or by treating them with superheated steam in a closed cylinder. See OILS.

Nebo. See BABYLONIA (*Religion*).

Nebraska, popularly known as the 'Black-water State,' is one of the north-central states of the American Union and fifteenth in area. It lies between 40° and 43° N. lat., and between 95° 23' and 104° W. long., and is bounded by South Dakota, Iowa, and Missouri (across the Missouri River), Kansas, Colorado, and Wyoming. Area, 77,510 sq. m., of which one-fifth is in improved farms. The surface is chiefly an elevated, undulating prairie; it is very level in the eastern and southern portions, but in the north and west the 'Bad Lands' extend into the state, while to the north of the Niobrara River there are great sandhills, composed of pebbles, gravel, and sand, covered for the most part with a sparse vegetation. The average elevation of the state rises from about 1200 feet in the east to 6000 feet towards the western border. The principal rivers are the Platte, Niobrara, and Republican, all flowing east. The atmosphere is dry and invigorating, and, though great extremes of heat and cold are sometimes experienced, they are not usual. There are few swamps and marshes. The rainfall is unequal, ranging from 30 or more inches in the east to 15 or less in the west. Temperature also has a wide range. Antelope are seldom seen, but the coyote, large timber wolf, fox, skunk, rabbits, &c. abound.

The soil of Nebraska, except in the Bad Lands and sandhills, is mostly a rich black mould, 2 to 8 feet in depth. The staple crop is maize, of which enormous quantities are grown. Tobacco and the sugar-beet also are cultivated successfully—the latter, however, in small quantity as compared with several other states. There are a number of factories for the manufacture of beet-sugar. Other important crops are maize, oats, wheat, barley, flax, potatoes, and buckwheat. In the western part of the state the droughts are hurtful; there flowing wells are rare, and irrigation is needed. Forests are nowhere found, and tree-planting has been extensively practised. The uncultivated lands yield great quantities of hay, and Nebraska holds a good place among the stock-raising states; sheep, horses, and mules are raised, cattle in the western uplands, and hogs in the east. The live-stock trade has its headquarters in Omaha, which in this respect ranks after Chicago and Kansas City.

While there are numerous factories in the eastern and southern parts of the state, the principal industries are limited to manufactures based on agricultural and stock-raising products—viz. slaughtering and meat-packing, flour and grist mill products, cheese, butter, and condensed milk. In minerals it is not rich. Its potash lakes were exploited during the Great War. The ever-changing current and dangerous sand-bars of the Missouri discourage

river trade; but the trade by rail (6000 miles) is very heavy. Omaha and Lincoln are ports of entry.

The state university is at Lincoln. Nebraska is well supplied with schools for higher education, and its public schools have a daily attendance of about 300,000 pupils, with 15,000 teachers. The state and private charitable institutions also are numerous. Industrial education has received special attention. Pop. (1880) 452,402; (1900) 1,066,300; (1910) 1,192,214; (1920) 1,296,372. The principal cities are Omaha (191,601) and Lincoln, the capital (54,948).

History.—Nebraska was included in the Louisiana Purchase, and was for many years a part of the North-west Territory. The way was prepared for settlers by the overland emigration to California in 1849. Nebraska territory was organised in 1854, with an area of 351,558 sq. m.; it extended north to British America, and west to the Rocky Mountains. But of this vast area great portions were afterwards carved out for Colorado, Dakota, and Idaho. Nebraska became a state in 1867.

Nebraska River. See PLATTE.

Nebuchadnezzar, better NEBUCHADREZZAR. See BABYLONIA.

Nebulæ are cloudy patches of light in the heavens. Some, as those in Andromeda and Orion, are visible to the naked eye, but the greater number can only be seen in telescopes of considerable power. Halley in 1716 gave a small list of 6 nebulae, but the chief workers in this field are Messier, who in 1784 catalogued 103; Sir W. Herschel, who alone discovered more than 2500; and Sir J. Herschel, who added to them more than 2000. These lists, however, include many star-clusters. Many objects which appear to be nebulae when examined with small telescopes are resolved by larger ones into clusters of stars. That some nebulae are not unresolved clusters of stars was shown by Huggins, who found that their spectra consisted of a few bright lines, and not, like those of the sun and stars, of a bright band crossed by dark lines. These nebulae were thus proved to consist of luminous gas. The chemical origin of the brightest of the lines found in the spectra of nebulae is still unknown, and is attributed to a hypothetical gas, *nebulium*. Other lines in the spectra have been identified as due to hydrogen and helium. The application of photography has revealed the great extent and intricate structure of many of the extended nebulae and those of spiral form. Large reflectors have usually been employed on account of their great light-gathering power. The photographs taken by Common, Roberts, Keeler, and Ritchey may be specially mentioned. In addition, photographs taken by Barnard and others have shown that a faint and diffused nebulosity is sometimes found extending over large areas of the sky. Nebulae may be divided into three classes: (1) *Extended Nebulae* like that in Orion. These have little motion, and give a bright line spectrum. Photographs show dark patches which must be attributed to non-luminous nebular matter. (2) *Planetary Nebulae*.—These show a sensible disc of diameter from 15' to a few seconds. Their spectra contain bright lines. They are masses of gas of much greater extent than the whole solar system. About 150 are known, and they show a tendency to congregate in the Milky Way. (3) *Spiral Nebulae*.—These are so called from their shape. Condensations usually occur in the arms of the spirals. They show a continuous spectrum with absorption-lines like stars. The nebula in Andromeda is in this class. These nebulae are very vast bodies at great distances from the solar system moving with velocities of

hundreds of kilometres per second, and the suggestion has been put forward that they consist of great aggregations of stars external to our galactic system. Another view is that they are rotating masses of gravitating gas in an extremely tenuous condition. For a mathematical treatment of this hypothesis reference may be made to Jeans's *Cosmogony*. Some of these objects are at such a great distance that light takes a million years to reach the earth from them.

NEBULAR HYPOTHESIS.—A striking feature in the solar system is that the planets are nearly in the same plane and move round the sun in the same direction. The moon and the large satellites of Jupiter and Saturn are also in this plane and moving in the same direction. Further, the sun, planets, and satellites are revolving in the same direction round axes which are perpendicular to this plane. All the members of the solar system known in the time of Laplace had this remarkable characteristic, though a number of exceptions, usually of small bodies, occur among members which have been discovered during the last century. As an explanation of this community of motion Laplace put forward the theory that the solar system had been formed by the gradual condensation of a large disc of gas or nebula. This he supposed to have been rotating in its own plane. Under the influence of gravitation it collected together, but, in consequence of the rotation, masses which formed planets were successively thrown off, and the main bulk of the nebula contracted further and now forms the sun. The existence of nebulae in the sky of forms which suggest rotation makes this hypothesis extremely plausible. But from our knowledge of the movements of the bodies composing the solar system the moment of angular momentum—which is a measure of the spin of the system—can be calculated. Dynamics teaches that this moment of angular momentum remains constant. Thus the spin of the original nebula can be calculated, and it is so small that planets would not have been thrown off. Many attempts have been made to modify Laplace's hypothesis, but in vain. Recently a very complete examination has been made by Jeans, who concludes that the peculiarities of the solar system cannot be explained in this way, and advances, what seems at first sight a very unlikely hypothesis, that the planetary system has been brought about by the near approach of two stars (Jeans, *Cosmogony*).

Necessaries. See INFANT.

Necessity may be *natural*, according to the laws of nature; *logical* or *mathematical*, according to the laws of human intelligence; *moral*, according to moral law. See CAUSALITY, LOGIC, ETHICS, KANT, EMPIRICISM. Necessity, Necessitarianism, or Necessarianism, is also a name for the view that denies the freedom of the will. See WILL.

Neck. See SPINAL COLUMN, THROAT.—Of diseases of the neck, STIFF-NECK is the term commonly applied to a condition of the neck in which lateral movement of the head causes great pain, and which is due to rheumatism of the muscles lying on the side of the neck, especially the sternomastoid. In the great majority of cases only one side of the neck is affected, the head being drawn more or less obliquely towards that side; but occasionally both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forwards. As long as the head is allowed to remain at rest there is merely a feeling of discomfort; but every movement is extremely painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes round the

neck (see RHEUMATISM).—*Derbyshire Neck* is a synonym for Goitre (q.v.).—For Necks in geology, see IGNEOUS ROCKS.

Neckar, one of the largest tributaries of the Rhine, and the principal river of Württemberg, rises on the eastern declivity of the Black Forest, near the village of Schwenningen. It has a winding course of 250 miles, and joins the Rhine at Mannheim—the other towns on its banks being Tübingen, Stuttgart (Cannstadt), Heilbronn, and Heidelberg. From Plochingen it is navigable. Fair wines are grown on its banks.

Necker, JACQUES, a famous financier and minister of France, was born 30th September 1732 at Geneva, where his father, a native of Küstrin in Brandenburg, had become professor of Public Law. At fifteen he went to Paris as a clerk to the banker Vernet, and in 1762 established the famous London and Paris bank of Thellusson and Necker. His public career commenced with his becoming a syndic of the French East India Company, as well as minister for the republic of Geneva at Paris, and with his marriage (1764) to the charming, accomplished, and ambitious Suzanne Curchod, who was born in 1737, the daughter of a pastor near Lausanne, and had loved Gibbon for five years with a constancy of which his colder temper was not worthy. The rich banker had first wooed Madame de Verméneux, a wealthy young widow, who scrupled at her suitor's lack of nobility, but he easily transferred his affections to her young protégée, and he proved till death an affectionate and faithful husband. She was religious and above reproach in character, yet her *salon* became a centre of all the intellect of Paris, and her Fridays drew together such celebrities as Grimm, Diderot, the aged Buffon, Marmontel, Thomas, D'Alembert, and the Abbé Galiani. In 1773 Necker gained the prize of the French Academy for an *éloge* on Colbert, and in 1775 he distinguished himself still further by his *Essai sur le Commerce des Grains*, in answer to the free-trade policy of the great Turgot, in which he claims for the state the right of fixing the price of grain and, if necessary, of prohibiting its exportation. Already also he had lent money to the needy government when in 1776, Protestant as he was, he was made Director of the Treasury and next year Director-general of Finance. He devoted five years of hard work to his hopeless task, and, if he showed no great statesmanlike foresight, he proved himself an honest, prudent, and sagacious minister. Indeed, some of his remedial measures were a real boon to suffering France, as his more equitable adjustment of taxes, his establishment of state-guaranteed annuities and *monts de piété*. But his most ambitious scheme—the establishment of provincial assemblies over all France, one of the functions of which should be the apportionment of taxes, proved a disastrous failure. His retrenchments were hateful to the queen, and the publication in 1781 of his famous *Compte Rendu*, a plain statement of the financial state of France, was promptly made the occasion for his dismissal. He retired to Geneva, carrying with him the respect of all Frenchmen; and here he busied himself with writing, and married his only daughter in 1786 to the Swedish Baron von Staël-Holstein. In 1787 he returned to Paris, and when M. de Calonne at the opening of the Assembly of Notables in that year cast a doubt on the truth of the *Compte Rendu*, he published a justificatory minute, which drew upon him the king's displeasure and his banishment to a distance of forty leagues from Paris.

He was recalled to his former office in September 1788, and quickly made himself the popular hero of the hour by recommending the summons of the States-general. But the successful banker was in-

fatuated with his popularity, and quickly proved himself unfit to steer the ship of state amid the storms of revolution, while his constitutional irresolution in the hour of danger drew the well-meaning king into the fatal error of being forced into recognising the union of the three estates, instead of taking the lead in freely granting what was inevitable. On the 11th July, while sitting at dinner, he received the royal command to leave France at once, but the fall of the Bastille three days later frightened the king into recalling him amid the wildest popular enthusiasm. But now his incompetence for greater matters than accounts was at length fully discovered, and after with fatal obstinacy spurning the help of Lafayette and Mirabeau, and leading the king to surrender his suspensive veto and the Assembly to stultify itself by a self-denying ordinance that ministers should not be chosen from its members, which made a really responsible parliamentary government in France impossible, he finally laid down his office unnoticed and without regret, after the carrying of Mirabeau's scheme for relieving immediate financial distress by the issue of *assignats*, September 1790. He retired to his estate of Coppet near Geneva, and here his wife died, 6th May 1794, while he himself, after publishing books which had no longer any importance, followed her on 9th April 1804.

The only other works that need be named are *De l'Administration des Finances de la France* (3 vols. 1784), *Sur l'Administration de M. Necker, par lui-même* (1791), *Du Pouvoir exécutif dans les Grands États* (2 vols. 1792), *De la Révolution Française* (last ed. 4 vols. 1797), and *Dernières Vues de Politique et de Finance* (1802). A collected edition was edited by his grandson (15 vols. 1820-21). See also the *Manuscrits de M. Necker*, published by his daughter in 1804; and for his life, her work, *La Vie privée de M. Necker* (1804), and his grandson's *Notice sur la Vie de M. Necker*, prefixed to the collected edition of his works. Five volumes of *Mélanges* from his wife's journals and papers were printed (1798-1802). Her story is charmingly told, from the papers preserved at Coppet, in the Comte D'Haussonville's *Le Salon de Madame Necker* (1882; Eng. trans. 1882). See M. G. Parry, *Mme. Necker* (1913).

Necklace, DIAMOND. See DIAMOND NECKLACE.

Necromancy, an ancient mode of divination by conjuring up the spirits of the dead to give answers about the future. A classical example is the Old Testament story of the witch of Endor. The eleventh book of Homer's *Odyssey* bears the title of *Nekromanteia*, and in it the shade of Tiresias is brought up and consulted by Ulysses. In most parts of Greece necromancy was practised by priests or consecrated persons in the temples; in Thessaly it was the profession of a distinct class of persons called Psychagögoi. See DIVINATION.

Necrosis (Gr. *nekros*, 'dead') is a term meaning the death of a localised portion of tissue. It is most commonly applied to death of part of a bone, either directly from injury or from violent inflammation. Death of a thin superficial layer, which is not enclosed in a shell of new bone, is usually termed *exfoliation*, and the more gradual destruction of cancellous tissue, Caries (q.v.). The bones of the lower extremity—the femur and tibia—are those which are most frequently affected by necrosis, but any bone may be the seat of the process. The jawbones, however, very often suffer from it in persons engaged in making lucifer matches. The more general use of red or amorphous Phosphorus (q.v.) for this purpose has rendered necrosis of the jaws much less common. The dead bone, known as the *sequestrum*, presents a rough appearance, as if worm-eaten. If the membrane investing the bone (the periosteum) remain healthy, a shell of healthy bone completely invests the dead portion. The

essential point in the treatment is the removal of the *sequestrum*, which is too purely a surgical operation to be described in these pages.

Nectar, the name given by Homer, Hesiod, Pindar, and the Greek poets generally, and by the Romans, to the beverage of the gods, their food being called *Ambrosia* (q.v.). But Sappho and Aleman make nectar the food of the gods and ambrosia their drink. Homer describes nectar as resembling red wine, and represents its continued use as causing immortality. By the later poets nectar and ambrosia are represented as of most delicious odour; and sprinkling with nectar, or anointing with ambrosia, is spoken of as conferring perpetual youth, and they are assumed as the symbols of everything most delightful to the taste.

Nectarine. See PEACH.

Need-fire. See FIRE.

Needle-gun. See BREECH-LOADING, RIFLE.

Needles of bone with eyes have been found dating from Aurignacian and Solutrean times, much finer ones from Magdalenian. These were shaped with a flint implement, rounded by rolling in a groove in a stone, and pierced with a flint awl. In later times there were eyed needles of bronze and iron. Savage races use needles of various materials, such as bone, ivory, wood, and metal. Some tribes do their sewing with awls of bone or of thorns with which they make holes, and then by pushing and pulling work the thread or string through them in the same manner as a shoemaker does. The Fuegians in sewing skins even make a tie at every hole. The Kaffirs make needles of iron or steel, with a constriction under the pin-like head, round which the end of the thread is tied instead of being passed through an eye.

Steel needles were made in 1370 at Nuremberg, at which early time its artisans were skilled in working metals, including the drawing of wire in iron, steel, and brass. Previous to 1563 the wire used for making needles in England was imported from Spain and Germany, but in England the manufacture was not of much importance till about 1650. The early-made needles were all square-eyed. The seat of the needle-manufacture in Great Britain is at Redditch near Birmingham, where in the best factories considerable improvements have in recent years been effected by the adoption of new mechanical appliances, and especially of automatic machines in some of the processes. See SEWING-MACHINE.

Needles. See WIGHT (ISLE OF).

Needlework. See BAYEUX, EMBROIDERY, LACE, TAPESTRY.

Neerwinden, a small village in the north-west corner of the Belgian province of Liège, is noted for the victory gained by the French under Luxembourg over the English under William III. (29th July 1693), and also for the defeat of the French under Dumouriez by the Allies under the Prince of Coburg (18th March 1793).

Ne Exeat Regno, a writ issued by a superior court to prevent a person leaving the country unless he gives security to abide a decree of the court.

Negapatam, a seaport of British India, on the Coromandel coast. Originally a Portuguese settlement, it was taken by the Dutch in 1660, and by the English in 1781. The port trades in cottons, live-stock, ghi (exported), and spices, piece-goods, coal, gunny bags (imported), chiefly with Burma, the Straits Settlements, and Ceylon. Pop. 54,000.

Negri, ADA, Italian poetess, born in 1870 at Bari, of working-class family, taught in a village school, and afterwards in a normal school in Milan. She first attracted attention by the revolutionary

spirit of two volumes of lyrics, *Fatalità* and *Tempeste*, expressing the bitter sufferings of the poor. Later works, such as *Maternità*, have not advanced her reputation.

Negri Bodies. See HYDROPHOBIA.

Negri Sembilan ('nine states'), one of the Federated Malay States, itself a confederation of Sungei Ujong (q.v.), Jelebu, Johol, Rembau, and five smaller states; area, 2550 sq. m.; pop. 180,000; capital, Seremban (17,000). See MALAY STATES.

Negritos is the name given by the Spaniards to the Negro-like Aetas, who inhabit the interior of some of the Philippine Islands. Under the same name anthropologists class the pygmies of the Andaman Islands (q.v.), the Semang of the Malay Peninsula, and the Tapiro and others of New Guinea. All these peoples are dark-coloured, with somewhat broad heads, frizzly hair, a stature of 4 feet 6 inches to 5 feet. They are at the lowest stage of culture, living upon what they can find or shoot with bow and arrow. Differing from these are the Sakai, another jungle-folk of the Malay Peninsula, brown, longer-headed, wavy-haired, blowpipe-hunters, with some crude agriculture. These are classed with the Veddas, South Indian jungle tribes, Toala of Celebes, and Australians as Pre-Dravidians. From all these are to be distinguished the African Pygmies or Negrillos. See ETHNOLOGY, NEGROES.

Negroes (African), properly speaking the dark-skinned, tall, or medium natives of Africa south of the Sahara; in a wider sense it is sometimes taken to include (a) Hottentots, (b) Bushmen, and (c) Pygmies or Negrillos. The Hamites of North and North-east Africa are not of Negro stock, though in many cases a larger or smaller admixture of Negro blood may be observed or inferred. By some authors a Bantu racial type is distinguished; but it must be borne in mind that the term Bantu is properly used of language only, and that many physical types occur among Bantu-speaking peoples; where a Bantu type is spoken of it may be taken to mean a long-headed people of medium stature, some of whom show facial characteristics of a non-negro type, such as a narrow nose.

Physical.—(a) The Negro proper is characterised by a dark skin, woolly hair, thick lips, a broad nose, and dark eyes; he is seldom really black, but at most very dark chocolate-brown; there are also reddish and yellowish types in many tribes; the hair is almost invariably black, but sporadic cases of red hair occur; white hair is found in the old, sometimes also in younger men; the eyes are dark blue at birth, but soon become dark brown. In stature the Negro varies considerably; some of the West African tribes do not exceed 5 feet 4 inches, but the Nilotic tribes (Dinka, Shilluk, &c.) are 5 feet 9 inches and over, and on the Shari the Kumbra stand nearly 6 feet. The shape of the skull is very varied; singularly enough the two groups just mentioned stand at the two extremes, the proportion of head breadth to length being 85 in the Kumbra and under 70 in the Dinka. Generally speaking, East Africa is long-headed, the area from Tanganyika to Chad extremely round-headed, while the remaining tribes are less pronounced.

(b) The Hottentot is of medium stature and long-headed, but his skin colour is yellowish-brown; he is commonly regarded as of Hamitic origin. The Bushman is likewise yellow-skinned, but he is some eight inches shorter than the Hottentot, and in head-shape the male Bushman seems to be rounder than the male Hottentot, but to resemble the female Hottentot.

(c) The Negrillo, or Pygmy, is shorter still; in one case a full-grown woman stood only 4 feet 2 inches; he is on the whole round-headed, but there is some

evidence of a long-headed type; his skin is reddish-yellow, and there is more body hair than in the Negro proper.

The Hottentot was in possession of the Cape and South-west Africa at its discovery, with the Bushman in the hinterland; the Negrillo lives in groups in the area from the great Rift Valley to the Atlantic. It is probable, from the evidence of physical types and from ancient records, that his range was formerly much wider; there is perhaps a Pygmy substratum in West Africa as well as among many Bantu-speaking tribes.

History.—Historical records are almost wholly lacking before the Middle Ages; ancient Egypt gives some data, and Herodotus has given an account of 'Ethiopians' in the army of Xerxes. It is commonly assumed that the earliest population was in occupation in the Old Stone Age, but it is at present uncertain of what type the most ancient skulls (Boskop, Broken Hill, &c.) are; there are no data to show at what period the Bushman and Negrillo appeared on the scene, but they probably preceded the Negro type, and he in turn was before the Hamite in most areas. In classical times the distribution of types must have been much the same as in the present day; but it can be safely affirmed that the Bantu-speaking peoples had not reached South Africa, nor yet, probably, the Hottentot. The story of the Nasamonians, told by Herodotus, reveals the presence of Negrillos on the borders of the Sahara, shown by the testimony of Hanno to have been either narrower or further south, or both, than at the present day. Though the earliest mention of Ghana does not go back earlier than the 10th century, there is reason to suppose that this great empire was in existence at least six hundred years; it seems to have had as its capital a town named Kumbi, two or three hundred miles due west of Timbuktu, in an area that is now extremely arid, but El Bekri speaks of its fertile fields, and its fall in 1240 must have been due in the main to change of climate. Its earlier rulers are said to have been white; in the 10th century the empire covered a territory as large as Nigeria, and its fame penetrated to Bagdad; El Bekri attributes to it a force of 200,000 warriors. It reached its end through conquest by the Mandingo empire of Mali, the wealth of which will be gathered from the fact that one of its rulers went to Mecca in the 13th century, taking, according to Ibn Khaldoun, 60,000 carriers and 3500 lb. weight of gold dust as journey money. Passing over other empires in this area, mention may be made of Edo, or Benin, famed for its wonderful bronzes; the present ruler, under British control, is the thirty-fourth king of the Yoruba line, which came in about 1140 A.D.; the Portuguese visited Edo towards the end of the 15th century. There are many other lines of native rulers who can trace their genealogy back some three or four hundred years, and among ancient kingdoms may be mentioned Bornu (Kanuri), attacked by Mali in 1374, Gao, Cayer, Sine, Dahomey, the Yoruba states, &c. The states of Equatorial Africa (Congo, Lunda, the kingdom of Monomotapa, &c.), were vastly less important than Ghana or Mali.

Population.—Estimates of the population of negro Africa vary enormously owing to the great differences of density of population; some authors put the figure at the absurdly low figure of 40,000,000, others give over 120,000,000; it is probable that Nigeria is the most densely peopled area, and the Southern Provinces average about 100 per square mile, with extremes of 3.5 for mountainous districts and nearly 450 for highly cultivated areas. The total population of Nigeria may number 20,000,000, on an area of 330,000 miles; this is ten times as dense as the population of the colony

of Soudan Français (Haut-Sénégal-Niger). West of Chad the population is about 35,000,000.

Non-Bantu languages occupy an area of about 2½ million miles, Bantu languages rather more; allowing 20 and 15 per square mile, a figure of 100 million is reached, which may be regarded as a minimum.

Language.—The term tribe is vaguely used, usually of a language unit; it is probable that there are at least 800 'Sudanic' and 300 Bantu languages. If the languages of Bushmen, Pygmies, and Hottentots are excluded, South Africa is the domain of the Bantu family, and the area from five degrees north of the Equator to the edge of the Sahara is occupied by Sudanic tongues, which are again divisible into classifying (with a syntax resembling Bantu), and non-classifying, which range from isolating tongues largely monosyllabic, like Ewe, to speech forms in which prefixes and suffixes are freely used. From the standpoint of etymology Sudanic and Bantu are related, for a large percentage of word roots are common to both, though they are, in the former, mainly monosyllabic, in the latter dissyllabic. Bantu languages are as nearly related as the different Germanic tongues of Europe; but the languages of the Sudan present great diversity. The main divisions are: West, Central, and East Sudanic (non-classifying), and the Middle Zone, mainly in mountainous, coastal, or otherwise uninviting regions, with Bantu-like syntax. Musical tones like those of Chinese are common both to Bantu and Sudanic languages. In addition to ordinary speech forms are found sacred and trade languages, and 'back slang.' Where language areas are small it is common to find people who speak three, four, or more languages with ease.

Religion.—No part of African anthropology has suffered more from distortion and inadequate presentation than the religion of the Negro, which is for many writers summed up in the word 'fetichism,' usually with a completely wrong meaning. Fetichism is properly the doctrine of spirits embodied in material objects, not the belief in the magical virtue of material objects in themselves. Such beliefs play a certain, often very subordinate, part in native beliefs, but they are nowhere predominant, and the word is better avoided as hopelessly ambiguous.

A certain number of authors have given adequate delineations of the religious beliefs and customs of individual tribes, but they are few in number. No generalised account can be given, for the simple reason that such an account must either be so much qualified as to lose its value, or so much cut down as to be comparatively meaningless; but a summary of some forms of African religion will make this diversity clear. It must be understood that such a summary is mainly concerned with the externals of the creeds; it is not impossible that there is much agreement in the ends which the native aims at—probably the preservation of life would cover the meaning of many practices.

There can be little doubt that the religions of Africa have undergone great changes; for Sierra Leone we have early records, which show that polytheism ruled where we now find belief in a single god with numerous nameless spirits, many of them localised; it is quite clear which form came first, but there is often a tendency to suppose that the simpler must precede the more complex.

There has been some controversy as to the beliefs of the Bantu-speaking tribes, more especially in the east and south-east; it has been argued that their religion is exclusively ancestor-worship without anything that can be called a supreme god; it is quite certain that a cult of ancestors bulks largely in their religion, but that is true of

many other parts of Africa. It seems probable that this cult has in some places obscured an earlier belief in a supreme being, often a sky-god.

On the other hand, it is probable that some of the supreme gods have come to occupy that position owing to alien influences, though this does not exclude the possibility that an indigenous figure of the same order has been supplanted.

At the present day the Temne of Sierra Leone believe in Kuru (Masaba) whom, owing to Islamic influence, they identify with Allah; no other named gods appear to be recognised, even among non-Mahomedan Temne; but they recognise the existence of numerous nameless *krifi* (spirits), good and evil, who have to be propitiated. There can be no doubt that to-day Kuru means sky; but an early voyage records that Cru was a single, very old tree; other gods of the same period were Benthema (the sun), Ymell (god of war). Of a wholly different type is the religion of the Yoruba, who recognise a sky-god, Olorun, but hardly worship him; they have also a host of other gods, some declared to be the descendants of Obatala, created by Olorun, and of Odudua, his wife. Their neighbours, the Edo, have a sky-god, Oisa, and below him a number of demi-gods (*ebo*), supposed to be transformed men. Different again is the Ibo creed, which sets Chuku (perhaps of alien origin) at the head, with non-human demi-gods (*alose*) below him, and also recognises protective deities, such as Chi.

Belief in the gods mentioned above is limited to a single tribe, but in other parts of Africa the same name is found common to many tribes; Nzambi (or a similar name) occurs among the Herero of South-west Africa, on the Congo, perhaps on the Gold Coast (Onyame), and among tribes west of Chad. Another name, chiefly East African perhaps, is Mulungu, which is the name given by the Zulu to the spirits of the dead; he is perhaps a generalised ancestor.

Traces of dualism (good and evil gods) are found here and there in West Africa; dualism is, however, mainly found among the Hottentots, Masai, and other tribes of non-negro speech; among the Bantu-speaking peoples it is reported only from Nyasaland.

It is commonly but erroneously supposed that the Negro is addicted to the worship of idols; there are many tribes which have no figures, human or otherwise, to which they offer worship; the wooden idols seen in museums are usually subordinate figures; it often happens that a special ceremony is needed, to make them efficacious in native eyes, before they are used as talismans.

Side by side with this kind of religion is the worship of ancestors, sometimes remote, sometimes only the immediate ancestors; in some tribes the main object is to appease or keep in good humour the spirit of the departed, but in others the main motive is to secure the welfare of the deceased or offer him a token of affection.

Habitations.—The dwelling of the Negro varies widely both in form and materials, ranging from the bee-hive huts of South Africa with wooden framework covered with grass, to the huge earth 'castle' of the Dagari and other tribes of the Black Volta River, which will house over a hundred and fifty persons, without counting cattle. The other main types are the round hut with conical roof, used in East Africa and the greater part of the Sudan, and the rectangular hut with gable or pyramid roof, found in the Congo and along the Guinea coast. Exceptional forms are in use among the Edo, who make houses with roofs covering the walls and passages, but leave the centre of each room open to the air; near Victoria Nyanza is found the *tembe*, a rectangular hut with

flat roof covered with a layer of clay. Pile dwellings are found sporadically.

The type of the village or town and its size are equally varied; huts may be ranged in one or more streets, sometimes radiating from a centre, or may be scattered irregularly over a wide area. In Sierra Leone it is rare to find a score of huts in a village, but in the Yoruba country there are native towns with over a hundred thousand inhabitants.

Dress.—There are some African tribes who still go wholly unclothed, like the Lobi and Birifo of the Black Volta; in other cases, like the Sara of the Shari River, an apron is worn behind; but the great majority of tribes wear something which the European would class as clothing, even if it is only a T bandage passing between the legs; where Mahomedanism has spread there is a tendency to wear a dress which completely covers the body. Cotton is grown in many parts, and, especially in West Africa, has probably replaced bark cloth. In the Sudan, East and South Africa, on the other hand, skin and leather were the accepted material for clothing before the introduction of European cloth. In the Congo palm fibre was largely worn; skirts of grass were also in use, especially among women.

At the present day ornaments are commonly of metal or glass, the latter in the form of imported beads; but side by side with these are found seeds, teeth, shells, strips of fur, &c. In the hair are used bone or metal pins; combs are made of wood or ivory.

Hairdressing.—Both for men and women there are an extraordinary number of styles of hairdressing in use, some dictated by custom, some by individual fancy; the latter often bear witness to earlier customs which have gone out of fashion. Some tribes shave the head completely; others only in part; others let it grow and interweave false hair, or vegetable filaments with it, or cover it with clay or other materials. Some construct sugar-loaf chignons, others have masses of hair resembling tam-o'-shanters. A result, perhaps of hair fashions, is the use of 'wooden pillows,' widely used in the Zambezi region, and sporadically in other parts.

Mutilations.—There are few Negro tribes but make use of some form of bodily mutilation; circumcision is practised in many parts—the central Guinea coast and the region from the Zambezi to Abyssinia being the chief exceptions. Operations on the teeth are also frequent, such as knocking out upper or lower incisors, chipping the incisors to a point, removing the sides in the middle of the tooth, but leaving the cutting edge intact, &c. Tribal marks, that is tatuing, or scarring of the face or body according to the tribal method, are largely used—in East Africa the lip-plug, a disk of wood sometimes three inches in diameter, is inserted in the lower lip; other tribes distend the lobes of the ear with discs of wood; occasionally the nose is pierced.

Food.—No general statement can be made as to the food of the Negro; the Pygmies and Bushmen are hunters, though the former obtain vegetable products from neighbouring negro tribes; the Hottentots and Herero live on the coagulated milk of their cattle to a large extent; but apart from these exceptions the native of Africa is in the main a vegetable feeder. There is, however, no one vegetable product in universal use, and the main food varies from one area to another. A general survey is the more difficult because we find cases, like the Konde, who form an islet of banana eaters, amid an ocean of tribes that subsist on millet and other cereals. Generally speaking, there are five main vegetable foods: yams, rice,

cereals such as millet and maize, manioc (cassava), plantains, or bananas. Of these, rice is mainly used in the extreme west, though it is also used in East and South Africa; yams are the food of the middle belt of Nigeria and adjacent parts; bananas are in use in Uganda and French Congo, and have been replaced in the Congo by manioc, introduced from America, which is also important in parts of Nigeria. For the remainder of Africa cereals of one sort or another form the staple food; as a curiosity may be noted the fact that the food of the Lango, near Victoria Nyanza, is a slightly fermented drink prepared from millet; they also make use of fresh or butter-milk. In West Africa the non-negro Fula alone use milk. It may be noted that the yield of native cattle is small, and in most cases they are soon dry.

It must not be supposed that the vegetable foods are consumed without any relish; dried fish, 'meat' sauce, palm oil, pepper, &c., are in use in various parts. After a sacrifice the flesh of fowls, goats, or cattle is eaten, though the portion which falls to each man is a scanty one. In many areas dependence upon one staple food means that before the new harvest is ready a 'hunger time' has to be endured, owing to the fact that the staple (e.g. yams) will not keep more than a certain length of time, or because not sufficient crops of cereals are raised; there are areas in which the population is dependent on roots and wild products at such a time. This is, however, often a result of improvidence, for other districts eke out their sustenance by maize, &c., planted at such a time that it is ripe when other supplies are beginning to fail.

Although each household is in the main self-supporting, it is usual, in areas where the market is known, for a small daily market to be held which, like the more important weekly market, is entirely devoted to the sale of food products. Ants, beetles, &c., are not despised as food by many tribes.

Domestic Animals.—Although there are few wholly pastoral tribes in Africa, domestic animals of one sort or another are seldom or never wholly unknown. In many parts dogs are eaten, even when they are also the hunters' aids. Cattle, where they are not kept either for milk or meat, may play a considerable part in tribal life as a means of exchange, especially when it is a question of purchasing a wife; edible domestic animals of all sorts are in demand for sacrifices. In addition to cattle, of which there are several breeds, and even more widely found, are goats and fowls; sheep are rarer, pigs only in certain areas. Milk and butter are in use only in the east and south, apart from such cases as the non-negro Fulani; the milk of goats is probably seldom or never used by non-pastoral tribes. Eggs are seldom eaten, and, among such tribes as permit the use of them, they are often forbidden to women. It may be noted in passing that some of the pastoral tribes draw blood from their living cattle for food purposes.

Hunting.—With the diminution in the amount of large game animals has disappeared the possibility of making large use of them as food, even in areas where antelope, &c., were formerly numerous. In some parts of West Africa there are hunters' societies, but even there the economic importance of game is small. Generally speaking, where the bush is dense the hunter lies in wait for his game—for following the tracks is uncommon—and waits till luck sends him a victim. Where the country is more open there may be a battue, and the animals are either shot down with antiquated firearms, or driven into nets or traps. In some cases, as with the elephant-hunters of the Baganda, the hunters may not eat of the kill, which is sold to neighbouring tribes. Traps

are made both for large and small animals, even including mice.

Fishing.—Fish form a relatively important part of the diet of many tribes, even when they are remote from the sea or large rivers. In some cases a riverain tribe exchanges fish for the agricultural products of an inland people, or they may be sold, in a dried state, in the ordinary way in a market, which can at times be smelt a mile or more away, for the fish are seldom thoroughly cured. Fish are caught with rod and line (rarely), spears, nets, traps, weirs, &c., and when the water is low they are poisoned or stupefied in great numbers in the smaller rivers and streams, which are dammed for the purpose. The tribes of South Africa form an exception to the rest of Africa, and make no use of fish as an article of diet, but it was recorded in the 18th century that the Bushmen of the west did not reject them. Fishing is an important industry on the Niger, especially in the upper waters, where large fish are caught on their way up-stream in July and August, and small fish, not so big as sardines, in the later months of the year; in April, when the waters have fallen, leaving lakelets easily cut off by dams, hundreds of men join forces to drive the fish into traps, while women on the banks clean them and put them to dry in the sun.

Stimulants.—Intoxicating liquors seem to be universally known; they may be classified into several types, according to the materials used in preparation, which include grain, bananas, honey, &c. The sap of the oil palm and the raphia palm is also fermented; it is agreeable when fresh, but after fermentation is very intoxicating.

Tobacco is largely used, either for smoking or in the form of snuff; pipes are made of a leaf twisted into a cone, of wood, or of clay. A water pipe is also known, introduced from Asia, which is chiefly used for smoking hemp.

Weapons.—Native weapons have in many parts given way to firearms, usually of an antiquated type. The indigenous weapons of Africa were the spear and bow, each with several different types, the club, the sword, the throwing spear and the throwing knife, the last three in limited areas only. Practically the only defensive weapon of importance was the shield, and this was unknown over a large area on the west from the Congo to the Cape of Good Hope. The shields are of several different types—interlaced, solid wood, leather or skin, &c. As poisons for weapons use was made of strophanthus and other vegetable products, snake poison, and putrefying animal matter.

Music.—There is little printed information regarding the vocal music of the Negro, but though monotonous it reaches, at least in certain tribes, a high level, both as regards choral and individual performances; melodies reproduced by the phonograph have surprised professional musicians by the accuracy with which difficult intervals are sung. Musical instruments of importance are drums (wood, wood and skin, or pot and skin), sometimes with cords to change the pitch, flutes and whistles, harps, and other stringed instruments, including the one-stringed bow, xylophones made of resonant pieces of wood over calabash sounders, &c. It is seldom that instruments of different kinds are played together; an orchestra of drums, on the other hand, is by no means uncommon.

Agriculture.—Generally speaking, farms may be classified under two heads, some being cleared by the efforts of the unit to which it will belong, while in other areas a large social unit clears the ground, which is then sub-divided. In grass country the grass is burnt, and the ground broken up by the hoe—the universal implement in Africa, with, however, great variations in size, length of handle, &c. Before hoes were introduced, probably the

digging-stick was in use. In bush or forest the undergrowth is cut and allowed to lie for some weeks till it is dry, and then burnt; the big trees are burnt where they stand, ashes being the only fertiliser known in most areas.

In West Africa the farm is cultivated for one, or at most two years, and is then left for ten or more years, during which dense 'bush' (i.e. a growth of small saplings ten or twelve feet high) springs up. In other cases the main crops may be grown for two or three years, less important ones for a year or two more before abandonment. One result of this system is the rapid disappearance of real forest in many districts.

Work is by no means at an end after the seed is put in the ground, which is, of course, done by hand; yams, maize, and other crops need hoeing up, and two or even three weedings are needed if the crop is to do well. After the harvest grain is stored in granaries, raised above the ground to keep off rodents, &c., or in tall earthen receptacles, in holes in the earth, &c.; yams are hung upon frames, plaintains may be dried to make flour later, and so on. Generally speaking, agricultural work is, among the Bantu, the duty of the women, and men do not do more than clear the ground; but in other tribes all the heavy work may fall to the men. While the crops are growing children are on the watch to scare baboons, birds, antelope, &c., which do great damage; fences are sometimes erected, especially against the wary hippopotamus, which suspects a trap everywhere. Harvest work is usually done by both sexes; for all kinds of agricultural work it is in many places the practice for the work to be done by large numbers of people, whom the owner of the farm provides with food.

Industry.—Among important manufactured products may be mentioned iron, smelted from ore in some places, and everywhere worked by blacksmiths who are in some tribes pariahs, and in others enjoy special consideration; weaving, done by both men and women, the former manufacturing a long narrow band of cloth on a loom with treadles, the latter a short broad piece, large enough often to be used as a 'cover cloth' for an adult; other manufactured articles are baskets and mats, and objects made of wood, such as figurines, combs, masks, &c. In West Africa gold has been for ages an important product; the Carthaginians bartered from the tribes on the coast. Salt is also a product which is in great demand; it is prepared from wood ashes, or won from deposits. Pottery is an important industry, carried on mainly by women; except in Bornu and a few isolated areas the wheel is unknown.

Calendar.—In parts of West Africa and the Congo the week is known as a unit of time, and varies in length from three to seven days; occasionally units of ten or more days are in use, sometimes side by side with the week; the month, where it is known, is always lunar, and is counted from the appearance of the new moon. Many tribes have no idea of the length of the year, though, of course, agricultural operations make them aware of its existence.

Market.—It is probable that in West Africa and the Congo the week came into existence as the unit by which the market was regulated; large markets, attended by thousands of people, are a common feature of this area; but they are not confined to it, as the markets of Uganda were also most important. In some parts a market 'queen' presides over the market; or it may be regulated by a king or chief, or their representatives, who collect a tax of 5 or 10 per cent. on the value of the wares, and preserve order. Theft in the market was, especially in the Congo, severely punished. On the banks of the Niger monthly

markets were known, with smaller fortnightly assemblies—people would come several days' journey by canoe to attend them.

Currency.—In parts of West Africa gold dust, weighed in the balance, is used as money; but apart from this, the only precious metals in circulation are the coins of various European nations. Over large areas cowries, of two different sizes, are current in West Africa, and more rarely in Bantu-speaking tribes; iron, in many shapes, such as hoes, spear-heads, needles, &c., as well as brass rods, manillas, copper crosses, &c., are among the metallic forms of currency, pieces of cloth, skins, tobacco, &c., are also current; and large payments may be made by means of cattle—a favourite unit when a wife has to be acquired. When cowries were first introduced two shells were sufficient to purchase a wife in Uganda; even in recent times, not more than a century ago, a thousand cowries would purchase a tusk weighing sixty pounds; now a large cooking-pot costs two hundred cowries. On the west coast cowries may be worth no more than four hundred a penny. There is often a special kind of numeration in use for counting cowries.

Transport.—In pre-European days all transport was effected by human beings, usually males, and almost invariably the load was carried on the head, though some Sierra Leone tribes use 'hammers' supported by a head-band, and resting on the back. The load which a carrier could transport ten or fifteen miles a day was and is about sixty pounds; but native traders will often carry much more, and cover more ground. The only exception to this mode of transport was when river or lake made canoes possible; especially on the Niger large trading canoes were in use.

Canoes.—The dug-out is the normal African boat, ranging in size from a craft big enough for one man only to sea-going vessels, big enough on the west coast in former times for sixty or eighty men. The Bantu-speaking tribes had canoes on the lakes, but those of the south had not even ferry-boats on the rivers, which constituted great obstacles to migrations such as those of the Angoni; the Baganda canoe was remarkable because it was sewn together. Canoes are always propelled by paddles.

Kinship, Descent, &c.—Little is known of many tribes with regard to Consanguinity and Kinship (q.v.); but it is clear that some have the same kind of relationships as are found in Europe, while in other cases the classificatory system is in use. In the latter case we may find the 'global,' or great family, with a head of the family ruling over his brothers and cousins, their descendants of all generations, and an equal number of unfree. Under this régime brothers and cousins are called by the same term, as are sons, nephews, and the children of cousins. Every member of such a family remains in it as long as he lives, whereas in the 'little' family a man leaves it at marriage and begins a new family on his own account. Each member of a 'great' family owes to it a certain amount of work, and can demand from it support and succour; it is responsible for the debts of the bankrupt, and must pay the fines of the criminal. It often happens that there is no term for brother, but only for elder or younger brother; a word may mean sister when used by a woman, or brother when used by a man, but it cannot be used by a man of a woman. In a certain number of tribes a double system of descent is found, reckoned for some purposes through the father, for others through the mother.

Marriage.—Two sharply defined forms of marriage are found in Africa; in the first the wife remains in her own family and her children with

her, so that, if any of them die, it is incumbent on the woman's family to bury them; the children do not inherit from their father. This may be called 'free' marriage; it is still found in Dahomey and Nigeria, but has in most parts been superseded by 'bond' marriage, where the wife is purchased by the husband, enters his family, passes to his heir at his death, and bears children who may be his heirs. Betrothal may take place in infancy. There are impediments, such as those set up by consanguinity or kinship, by membership of the same totem clan or other social unit, &c. A man may have as many wives as he can get, the first being 'head' wife; but the details are too numerous to permit of a conspectus, and must be sought in anthropological works. The head wife usually occupies a favoured position, and may be her husband's deputy during his absence; she often wields authority over the inferior wives. The age when a girl goes to her husband is commonly soon after the age of puberty. Where there are a number of wives they commonly take turns to cook for the husband. Important chiefs may have several score of wives, and go on acquiring new wives till the end of their lives; as a result it is possible to find families of a hundred half-brothers and sisters. There is very little in the way of any actual marriage ceremony; the important element is often a sacrifice to the ancestors, performed long before the girl goes to her husband, and the wedding may consist in no more than a semi-ceremonial home-bringing of the bride by an escort, usually of the husband's family. Where betrothal has taken place in infancy it is usually possible for the girl, on reaching an age when she can exercise choice, to decline her suitor; in this case her family has to refund the value of the payments on account of bride-price; the same is the case when a 'bond' wife leaves her husband—in both cases a favoured man often finds the money. Generally speaking the Negro takes considerable pains in choosing a wife, making inquiries as to her family, &c. Although there is little which looks like love-making to European eyes, marriages of affection are probably not uncommon; it is probably rare for a wife to be really badly treated.

Disposal of the Dead.—The corpse is disposed of in a multitude of ways. It may be buried in the hut, which may remain in use or be deserted; it may be inhumed in the bush, by the wayside, in a cemetery appropriated to certain social units, &c., or it may be deposited in a tree, the bed of a stream, on a platform, or exposed. It may be mummified, dried over a slow fire, or eaten; the bones may be collected when the flesh is off them, or the head alone may receive special treatment. The grave may be lined with stones, have a side chamber, or a hood in which the head of the corpse goes, or the body may be put in a pot. Where the corpse has been buried funeral rites may still go on till after 'second burial,' a ceremony intended to send the soul of the dead man to his own place. During the burial customs there may be human or other sacrifices; the flesh of animals otherwise tabu may be eaten by the family of the deceased, and so on. Cremation is not absolutely unknown. Some tribes bury property with the corpse, and the wives of the deceased were formerly sent after him to attend him in the next world. On the grave are often offerings of food, &c., for the benefit of the deceased. Custom prescribes that certain relatives must mourn, especially the widow, lest the spirit of her dead husband haunt her.

Inheritance.—Property, especially in land, may be classified under three heads according to whether it is owned by the community, by a family, or by an individual. Individual property may pass to heirs in the male line, who are either

own children, brothers, or brothers' sons, or may go to the eldest among them. If uterine succession is the rule the heir is the sister's son; but hybrid systems are not uncommon and the nearest heir may be a brother (uterine), with a sister's son or daughter next in succession. The son of the head wife often takes a double, or at least a large, share where there is a division of property, but there are also cases in which the youngest son is in the favoured position. The wives of a dead man may pass under the same rule as the rest of the property, but the own mother of the heir is commonly excluded. Whoever buries a debtor may succeed to his liabilities.

Cannibalism.—The eating of human flesh was formerly widespread in Africa, and it is probably not yet extinct. Two kinds may be distinguished—the ceremonial meal eaten because of some magical virtue or other advantage to be gained; the other, food cannibalism, practised because human flesh tickled the palate. Witches, male and female, are frequently regarded as eaters of human flesh, and are compelled to undergo the ordeal of drinking poison.

War.—Before European domination brought peace to Africa some tribes were essentially warrior peoples, and depended on raiding for their subsistence, and certain states, like Dahomey, were essentially military in character. But in the case of many tribes war, properly so called, was hardly known. In the Ibo country one town might fight another over the abduction of a woman, and hostilities would go on for two or three years, ceasing in the heat of the day and in the farming season; then, two or three having been killed on each side, the contending parties would decide that enough blood had been shed, and make peace—needless to say there was never any question of either booty or increase of territory. In contrast with this picture may be considered the Baganda, who at the slightest pretext sent an expedition against another nation, and had an annual war against the Banyoro. Generally speaking, tribes whose territory was small were peaceful; but expanding peoples, like the Yoruba or Bantu, generally depended much upon their prowess in war.

Slavery.—When African slavery is spoken of it must be borne in mind that domestic slavery was a social practice which differed completely from the slavery to which the Negro was condemned when he was carried overseas. Where a slave was not sold away, and even in the frequent cases where prisoners of war formed the main mass of the unfree, the lot of the slave was by no means an unhappy one; he could marry a wife, and own property, even other slaves, who relieved him of the duty of working for his master; he was free in many cases at certain times or on certain days of the week, and some tribes permitted a slave to purchase his freedom with his savings. So contented were the slaves in some places that opportunities of escape would not be taken. In some tribes children or grandchildren of a slave became free, and 'house' slaves (i.e. those born in the house) could not be sold. In places a slave could, if he were ill-treated, transfer himself to a new master by performing the appropriate ceremony.

Folk-tales, Proverbs, &c.—Myths are rare among negro tribes, but they have a great wealth of tales and proverbs. In the former animals often figure largely, and there is often a cunning beast which outwits his brethren. In the Congo the proceedings at the trial of a law-suit were largely of the nature of citation of precedents, in the form of tales, and judgment might depend upon what the leopard once said to the elephant.

Bibliography.—No complete list of words can be given, but for a popular account of native life the

best work is A. Werner, *British Central Africa* (1906); Roscoe, *The Baganda* (1911), is more detailed; M. Delafosse, *Haut-Sénégal-Niger* (1912), is a summary of official information from a French colony; J. Spieth, *Die Ewe-Stämme* (1906), is a native account with parallel German translation.

NEGROES IN AMERICA.—Importation of slaves from Africa went on steadily from the early years of the 16th century, when it was begun by the Spaniards, even the good Las Casas recommending it in the interest of the native Indians. Both Queen Elizabeth and King James I. issued patents to English slave-trading companies operating between the coast of Guinea and the American colonies. England, by the treaty of Utrecht (1713), engaged to carry out the contract of the old French Guinea Company, and to import into the New World 130,000 slaves in the course of the next thirty years, and is said to have more than made good the engagement. In the United States the traffic was open and active until the passage of the act of 1794 prohibiting the importation of slaves into any of the federal ports. Long after this it continued to be a brisk business in the West Indies and South America. As late as 1840 there were seventy-five ships plying constantly between Brazilian ports and the African coast, bringing cargoes of 300 or 400 slaves at each trip. The principal points at which the slaves were obtained were along the coast of Guinea, especially on what was known as the Slave Coast, between the rivers Lagos and Assinie, where were the crowded marts of Waidah and Anamaboe, and again along the Angola coast, from 8° to 18° S. lat.

The folk-tales of the race in America are very numerous, the negro being a tireless talker and *raconteur*. Many of them reveal a high stage of the art of story-telling, as the Georgia tales collected by J. C. Harris and Colonel C. C. Jones. Many of them belong to the class of 'beast-fables,' similar to some which have been collected among the American Indians and the natives of the African continent, and such as were favourite staples of amusement in Europe during the middle ages. One of the principal figures is the rabbit (the 'brer rabbit' of the 'Uncle Remus' tales). He figures conspicuously not only in the southern United States, but in the West Indies and on the Amazon (Hartt), and as *tio conejo* ('uncle rabbit') in the folklore of the Venezuelan negroes (Dr Ernst). Along with story-telling, singing and music are favourite diversions of the coloured population. This tendency is a direct inheritance from their African ancestry. In Central America the negroes still employ the *marimba*, an African instrument with wooden keys placed over jars or gourds, the keys being struck with a stick. In the United States the violin, the fife, and the guitar are used, but the favourite is the banjo, an instrument modified from the guitars with grass strings used on the Guinea coast. The negro folk-music of America, however, is European in origin, though it has developed in its own way; and it has returned to Europe in coon-song and ragtime. No American negro composer has attained celebrity. (But see COLERIDGE-TAYLOR for an English-Sierra Leone mulatto.) Their songs are numerous, many of them of a religious character, others turning on the incidents of daily life. They are generally defective in prosody and without merit, being often little more than words strung together to carry an air. Paul Lawrence Dunbar (q.v.) was, however, a poet of some eminence. Frederick Douglass, Burghardt du Bois, and Booker T. Washington were all coloured men. And it should be remembered that in France Alexandre Dumas was a quadroon. The American negro has done nothing in the plastic arts to be set

against the wonderfully fine carvings of former ages in Guinea and elsewhere.

The social position of the members of the race in some parts of South America is little different from that of the whites. This is also theoretically the case in the United States since the civil war; but the natural sense of inequality between the two races makes itself felt. Some states have adopted voting qualifications, educational, proprietary, or other (such as the 'understanding clause' and the 'grandfather clause'), which practically disfranchise the negro; though the states have representation in congress in proportion to their population, including negroes. Many thoughtful and learned men see in the increasing coloured population a standing menace to the institutions and culture of their country. During and after the Great War economic forces drove many negroes into the towns of the north and west, and the coloured population of some of the southern states fell between 1910 and 1920. However distasteful this movement may be to the north, it has probably helped to slow down the increase of the coloured population of the United States; and the slowing down was already greater than among the whites.

Nehemiah was, according to the prophetic book named after him, a Jew who had for some time held the post of cupbearer to Artaxerxes [Longimannus], 'King of Babylon' (xiii. 6), when, at the winter-palace of Shushan or Susa, towards the end of the year 445, he was surprised and saddened with unexpected tidings of the very unprosperous state of Jerusalem. How or when the events now for the first time reported to him had happened is not related, but the result had been to leave the city impoverished and defenceless. In the following spring (444), having obtained leave of absence from court for a limited time, and full powers to act as governor-extraordinary of Judæa, he set out without delay for the city of his fathers. The first necessity was to have the walls rebuilt; on his arrival no time was lost in taking the necessary steps, and the entire structure was completed, in the face of much opposition, within fifty-two days from its commencement (vi. 15). His next care was to reinforce the population of the depleted capital by drafts from the surrounding districts, and in particular, it would seem, to bring back to town the Levites who, through non-payment of dues, had been compelled to abandon service at the temple and give themselves to field labour throughout Judæa. Arrangements having been made for the regular support of the sacred offices, the feast of the dedication of the walls was now gone about with great pomp and joy. It is to be presumed that Nehemiah returned soon afterwards to his duties at the Persian court. We read (xiii. 6; cf. v. 14) of a second visit of Nehemiah to Jerusalem, twelve years afterwards, on which occasion he either initiated or renewed and completed certain reforms which henceforth were among the most characteristic features of post-exilic Judaism. One of the most marked of these was the crusade against mixed marriages and the separation of the Jews of pure descent from the 'mixed multitude'

(xiii. 3). His cleansing of the temple, and expulsion of Tobiah from its precincts, ultimately led, it would seem, to the formation of the Samaritan community as a separate religious organisation. Another of Nehemiah's reforms was the stringent enforcement of a strict law of Sabbath observance. Others are to be found in the arrangements he made for the permanent maintenance of the temple worship and the support of the priests and Levites. In this connection, and as bearing on the criticism of the Pentateuch, Neh. x. 32 [33] ought to be compared with Ex. xxx. 13, Neh. x. 33 [34] with Ex. xxix. 38, 39, and Num. xxviii. 3, 4; also Neh. x. 37 [38] with Lev. xxvii. 32, and Neh. x. 36 [37] with Num. iii. 12, 13. How long Nehemiah's second visit to Jerusalem lasted we are not told, nor does authentic history record the time or place of his death. In the late apocryphal book of 2 Maccabees a spurious letter, purporting to date from the year 124 B.C., is preserved, where wonderful things are told as to Nehemiah's rekindling of the sacred altar-fire by means of 'naphthar,' and it is also said (2 Macc. ii. 13) that he founded a library in which he 'gathered together the acts of the kings, and the prophets, and of David, and the epistles of the kings concerning the holy gifts.' This last statement can only be used with great caution as bearing on the history of the canon.

The canonical Book of Nehemiah originally formed the closing chapters of the undivided work, Chronicles-Ezra-Nehemiah (see CHRONICLES), for which two of the most important original sources were the highly characteristic memoirs of Ezra and Nehemiah. These have been preserved, however, only in so fragmentary and dislocated form that it is exceedingly difficult now to gather from them the true order of the events to which they relate. The book in its present shape begins (Neh. i. 1-vii. 5) with Nehemiah's account of the building of the wall and the difficulties he had to encounter. The depleted state of the city had suggested to him a census of Judæa, and in this connection is given the list of those who had come up with Zerubbabel nearly a century before (vii. 6-73 a); this list, apart from very numerous and considerable textual variations, is identical with that in Ezra ii. The reader might now expect to find a corresponding census for Nehemiah's own time, but instead of this the next three chapters give an account of the reading of the law by Ezra, the celebration of the feast of tabernacles, the fast and repentance of the people, and the solemn sealing of the covenant to observe the law. These chapters are continuous with Ezra x. In Neh. xi. the interrupted narrative is resumed, or rather the place of narrative is taken by a series of name lists (inhabitants of Jerusalem, heads of houses in Judah and Benjamin, priests, and Levites). Chapter xii. 27-43 then gives Nehemiah's description of the dedication of the walls, and the rest of the book (xii. 44-xiii. 31) consists of the account of the reforms he effected in the spirit of the covenant as contained in x. 30-39. It is very likely that the editor of Chronicles-Ezra-Nehemiah had before him two distinct documents relating to Ezra and Nehemiah respectively, but that into the first of these between Ezra x. 44 and Neh. vii. 73 b (originally continuous) he judged it expedient to introduce from the second a section of Nehemiah's memoirs (Neh. i. 1-vii. 5) in order to prepare the way for the mention of Nehemiah in Neh. viii. 9 and x. 1 [2]. The work mentions Jaddua, who was high-priest in the days of Alexander the Great, and also Darius, the last of the Persian kings (xii. 22). It cannot, therefore, have been compiled earlier than 333 B.C., and probably it ought to be dated at least half a century later. In the gradual compilation of the Jewish canon, the Ezra-Nehemiah section of

the larger book was first added to the list of authoritative writings, some account of the times subsequent to the captivity being plainly required. The need for a second history, parallel with that contained in the 'former prophets,' was not so obvious; Chronicles, therefore, the remaining portion of the work, was the very last to take a place among the Old Testament Scriptures.

See further the histories by Ewald, Stanley, Wellhausen, H. P. Smith, and S. A. Cook (*Ency. Brit.*, 'Jews,' 'Palestine'). For introductions and commentaries, see (besides the general handbooks on the Old Testament) Ryle (*Cambridge Bible*, 1901), T. W. Davies (*Century Bible*), Batten (*International Critical Commentary*, 1913), C. C. Torrey, *Ezra Studies* (1910), and Cook (*Ency. Brit.*, vol. x. p. 108, and '1 Esdras' in Charles's *Apocrypha and Pseudepigrapha*).

Neidpath. See PEEBLES.

Neilgherry Hills (properly *Nilgiri*; Sansk. *nīla*, 'blue,' and *giri*, 'mountain'), a mountainous district in the south of India, rising abruptly from the plains to the height of 6000 feet, though individual peaks shoot up to 8760 feet. The mass is entirely isolated, with the exception that a precipitous granite ridge leaves its western face and connects it with the Western Ghāts. The surface consists of grassy uplands with large groves of forest trees; but the lower slopes are heavily timbered. The Neilgherry Hills are inhabited by five distinct tribes, of whom the Todas are the most interesting. They speak a Dravidian dialect and practise polyandry; in 1881 there were 675; in 1921, 640. The men are tall and athletic, with Roman noses, black bushy beards and eyebrows, but they are dirty in their habits. Their sole occupation is tending cattle. Owing to their great elevation, the Neilgherry Hills have a delightfully cool climate, and are much resorted to on this account by invalided Europeans, the principal station being Ootacamund (q.v.). See H. B. Grigg's *Manual of the Nilgiri District* (1880); Rivers's *The Todas* (1906).

Neisse, a town of German Silesia, is situated in a broad valley on the Neisse, an affluent of the Oder, 50 miles SE. of Breslau. It manufactures linen and chemicals, and has great wool-markets. Pop. 30,000. Neisse was formerly the chief town of a principality, and residence of a prince-bishop.

Nejd. See ARABIA, WAHABIS.

Nekrasoff, NIKOLAI ALEXIEVITCH, a Russian lyrical poet, was born in Podolia in 1821, entered the army, but soon devoted himself to literature, editing a newspaper and a monthly magazine. He died 8th January 1877. Belonging to the realistic school, he gave powerful expression to the popular aspirations and social tendencies of his race in a series of poems that have been often re-edited.

Nélaton, AUGUSTE, surgeon, was born at Paris, 18th June 1807, studied there, and, after serving as surgeon in various hospitals and lecturing at the faculty of medicine, became in 1851 professor of Clinical Surgery, and in 1866 surgeon to the emperor. He became a member of the senate in 1868, and died 21st September 1873. Besides his great *Éléments de Pathologie Chirurgicale* (5 vols. 1844-60), he wrote on tumours of the breast, and the operation for cataract.

Nellore, capital of a Madras district, on the right bank of the Pennar, 107 miles N. of Madras. In 1787 a pot filled with imperial Roman gold coins and medals was found here, under the ruins of a small Hindu temple. Pop. 36,000.

Nelson, chief centre of the Kootenay silver-mining region, British Columbia, on a branch of the Kootenay Lake, having connection with the Canadian Pacific Railway; pop. 5000.

Nelson, a municipal borough of Lancashire (Nelson and Colne parliamentary borough), with great cotton-works, 3 m. N. of Burnley; pop. 40,000.

Nelson, the capital of a provincial district in New Zealand, is situated at the north end of South Island, at the mouth of the Maitai, a small river at the head of Blind Bay. The situation is very beautiful, on a flat, hemmed in by rugged hills and amidst almost tropical luxuriance. The harbour is sheltered and accessible to ships drawing 18 feet; and there is regular steam communication with Sydney and Melbourne. The city was founded in 1841; its water-supply is good. There are a cathedral, a literary institute and museum, public hospital, asylum, and (near by) research institute. The manufactures of the town comprise cloth, leather, soap, and jam. Pop. 10,000.

Nelson, HORATIO, VISCOUNT NELSON, English admiral, was born on 29th September 1758, at Burnham Thorpe in Norfolk, of which parish his father was rector. His mother, daughter of Dr Suckling, prebendary of Westminster, was related to the Walpoles. He entered the navy in 1770, under the patronage of his uncle, Captain Maurice Suckling; made a voyage to the West Indies in a merchant-ship; served in the Arctic expedition of 1773, and was afterwards sent to the East Indies in the *Seahorse*. Two years of the climate severely tried his constitution, never very strong, and he came home, invalided, in September 1776. In April 1777 he passed his examination, and by the interest of his mother's family was at once promoted to be lieutenant of the *Lowestoft* frigate, with Captain Locker. In her he went to Jamaica, where he was taken by the admiral into the flag-ship, and on 8th December 1778 was promoted to command the *Badger* brig, from which, six months later, he was posted to the *Hinchinbrook* frigate.

In January 1780 he commanded the naval force in the expedition against San Juan; in the heavy boat-work up the pestilential river his health broke down, and he returned to England in an apparently dying condition. A few months' rest and careful treatment, however, restored him; and in August 1781 he commissioned the *Albemarle*, in which, after a winter in the North Sea, he went to North America, where he joined the squadron under Lord Hood, and made the acquaintance of Prince William Henry, afterwards William IV., with whom he always maintained the most cordial relations. In the spring of 1784 he was appointed to the *Boreas* frigate, again for service in the West Indies, where, by enforcing the Navigation Act against the Americans, he roused the ill-will of the merchants, which took effect in numerous actions for damages. The law, however, was clear on the point, and Nelson's proceedings were sustained, though not without causing him much trouble and annoyance.

Whilst on this station he married Mrs Nisbet, the widow of a Dr Nisbet of Nevis, niece of Mr Herbert, the president of the island; and on the *Boreas* being paid off, in December 1787, he with his wife retired to Burnham Thorpe, where he lived for the next five years. His frequent applications for employment were unsuccessful, till, on the imminence of war with France in January 1793, he was appointed to the *Agamemnon* of sixty-four guns, in which he accompanied Lord Hood to the Mediterranean. When Toulon was given up to the allies Nelson was ordered to Naples to urge the necessity of troops being sent at once to their assistance; on his return he was employed in the blockade of Corsica, and in the following spring commanded the naval brigade which largely contributed to the reduction of Bastia and of Calvi,

where an unlucky blow from a bit of gravel, scattered by a shot, destroyed the sight of his right eye. In 1795 he was with the fleet in the two actions fought by Admiral Hotham outside Toulon. In both the French were defeated with some loss, but they were allowed to escape, and Nelson in his private letters expressed an angry opinion that more might and ought to have been done.

In the autumn of 1795 Hotham was succeeded by Sir John Jervis, and during the whole of 1796 the strictest blockade of Toulon was enforced, Nelson being for the most part, as in preceding years, with a small squadron in the Gulf of Genoa, where he put a stop to all coasting traffic, and commanded the road along the shore so completely as to warrant his assertion that, had he had an adequate force, the invasion of Italy would have been impossible. Towards the close of the year Spain concluded a treaty of alliance with France, and sent her fleet into the Mediterranean to co-operate with the French. Jervis thus found himself opposed by very superior forces; and, with Spain and Italy both in hostile hands, his position was no longer tenable. He withdrew the troops from Corsica, and retired to Gibraltar, and afterwards to Lisbon. He was, however, determined that the Spanish fleet, which had been instructed to join the French at Brest, should not pass; and, on its endeavouring to do so, met it off Cape St Vincent on 14th February 1797, and inflicted on it a signal defeat. This was rendered more decisive by the action of Nelson, who, having been appointed commodore, with his broad pennant on board the *Captain*, was in the rear of the line, and, interpreting a manœuvre of the Spanish admiral as an attempt to reunite the two divisions of his fleet, which Jervis had separated, wore out of the line to meet him, and for nearly half-an-hour withstood, single-handed, the attack of the whole Spanish van. When support arrived and the Spaniards fled, the *Captain* had suffered severely; and Nelson, being unable to join in the pursuit, let his ship fall foul of the Spanish *San Nicolas*, which he boarded and took possession of, and, leading his men across her deck to the *San Josef*, took possession of her also.

Nelson's conduct on this occasion deservedly won for him the cross of the Bath; and, being promoted in due course to be rear-admiral, he continued with the fleet off Cadiz till, in July 1797, he was sent with a small squadron to seize a richly-laden Spanish ship which had taken refuge at Santa Cruz. He was instructed to levy a heavy contribution on the town if the treasure was not given up; but the troops which he had asked for were not granted, the ships were powerless, and the landing force at his disposal was quite inadequate. With it, such as it was, however, the attack was made on the night of 21st July; but in the darkness the boats missed the mole, and landing irregularly, were repulsed with severe loss. Nelson himself had his right elbow shattered by a grape-shot. He was carried on board his ship, where the arm was amputated, but on rejoining the fleet he was compelled to return to England.

In the following March, 1798, he hoisted his flag on board the *Vanguard* of seventy-four guns, and sailed from St Helens to rejoin the fleet off Cadiz. He was immediately sent into the Mediterranean in command of a small squadron, with orders to ascertain the object of the French armament at Toulon. The secret was, however, too well kept; and the *Vanguard*, being dismasted in a violent gale, was obliged to put into San Pietro off Sardinia to refit, while the French expedition sailed on its way to Egypt. On 7th June Nelson was reinforced by ten sail of the line; but his frigates had all parted company, and, under some

misapprehension of orders, did not rejoin him. He was thus left without means of learning anything about the French further than that they had sailed from Toulon. His hope to get news at Naples proved vain, and it was only when he arrived off Messina that he heard that the French had captured Malta, but had sailed again some days before. Their destination was unknown; he conjectured that it might be Egypt, and he hastened thither, only to find that there was no trace of them. He had in fact passed within a few leagues of them, but without seeing them. He returned by the coast of Asia, put into Syracuse, where he watered, and was meditating going up the Archipelago to Constantinople, when he at last learned that, after all, they had gone to Egypt. Thither he immediately followed, and on the evening of 1st August found their fleet lying at anchor in Aboukir Bay. His plans had long before been formed and discussed with the several captains under his orders, everything was ready, and no explanatory signals were needed. His fleet was numerically inferior to that of the French, and became still more so by the accident of the *Culloden* getting aground and being unable to take any part in the battle; but the wind was blowing along the French line, and, by concentrating his attack on the weather end of it, it was crushed by superior force, while the leeward-most ships were unable to render any assistance; and thus, creeping gradually down the line, he captured or destroyed the whole, with the exception of the two rear-most ships, and two of the frigates, which fled.

Never, in recent times, had there been a victory so complete, so overwhelming; and when Nelson with his shattered fleet returned to Naples he was the object of an enthusiastic adoration which knew no bounds. The queen, in her intense hatred of the murderers of her sister, welcomed their conqueror with all the ardour of a passionate nature, and Lady Hamilton (q.v.), the wife of the English ambassador, fell on his breast in a paroxysm of hysterical rapture. A woman of extreme beauty, winning manners, and shady antecedents, first the mistress and then the wife of Sir William Hamilton, she enslaved Nelson by her charms, and the two became bound by a liaison which death only severed. At home Nelson was raised to the peerage by the title of Baron Nelson of the Nile; parliament voted him a pension of £2000 a year, and the East India Company awarded him a sum of £10,000. Turkey and Russia sent him handsome and costly presents, and the king of Naples conferred on him the title of Duke of Bronte, in Sicily, with an estate valued at £3000 a year, though during Nelson's life its revenues seem to have been in abeyance.

The government of Naples had already concluded an alliance with Austria and declared war against France; but the French army swept away the Neapolitan troops almost without resistance, and the Neapolitan Jacobins received their French brethren with open arms. For the king and his court safety was only in flight, and Nelson conducted them to Palermo. Afterwards, returning as the king's representative, he sternly annulled the convention which Cardinal Ruffo, contrary to the king's express orders, had made with the rebels; he forced the traitors to surrender at discretion, and he promptly hanged Caracciolo (q.v.), one of their leaders, who had added perjury to treason, and having accepted a command as commodore in the king's navy had betrayed his trust, and waged war against the authority he was pledged to maintain.

The affairs of Naples were not yet regulated, the outposts held by the French and their sympathisers were not yet all reduced, when, on July 19, 1799,

Nelson received an order from Lord Keith, the commander-in-chief in the Mediterranean, to bring or send the greater part of his force to Minorca, which he conceived to be threatened by a joint attack of France and Spain. Nelson refused to obey the order; and when it was repeated in still more positive terms, he contented himself with sending Sir John Duckworth, his second in command, while he himself remained at Naples or Palermo, and controlled the blockade of Malta which was carried on unremittently during the whole time. The Admiralty censured him for his disobedience; and indeed it can scarcely be maintained that the affairs of Naples were of such paramount importance as to justify this extraordinary breach of discipline, the motives of which have been much discussed. Perhaps the true explanation of his conduct is that a severe wound in the head, which he had received at the Nile, had seriously affected his general health, and caused a depression of spirits which it needed some violent stimulus to overcome. Happy at last in the capture of the two ships which had escaped from Aboukir Bay, he obtained leave to resign his command, which the state of his health rendered irksome, and made his way home overland, by way of Vienna and Dresden, in company with Lady Hamilton and her husband, for whom he professed and appears to have truly entertained a real affection and esteem. He arrived in England in November 1800. The four months spent on the journey had done much to re-establish his health, and he immediately volunteered for active service. His meeting with his wife could not possibly be a happy one; and after an angry interview they parted never to see each other again.

On 1st January 1801 Nelson was promoted to be vice-admiral, and a few days later was appointed second in command of the expedition ordered to the Baltic, under Sir Hyde Parker. He hoisted his flag in the *St George*, but that ship being too large for the approaches to Copenhagen, he moved into the *Elephant* when the attack was determined on. The whole conduct of this attack was entrusted to Nelson, with the smaller ships of the fleet, Parker, with the others, remaining at anchor some miles distant. After a furious combat of from three to four hours' duration, the enemy's ships were subdued. The shore batteries still continued to fire, till Nelson sent a flag of truce on shore to point out that the worst sufferers from the continued engagement were the crews of the beaten ships, which received a great part of the fire of both parties. A suspension of hostilities was agreed on to permit of the prisoners being removed; and this led to an armistice, which the news of the czar's death shortly afterwards converted into a peace. Nelson, who was raised a step in the peerage and became a viscount, succeeded Parker as commander-in-chief; but, his health having given way, he was permitted to return to England. He arrived in the beginning of July, and was at once ordered to undertake the defence of the coast, in view of the preparations for invasion which were being made in France; and though he failed in an attempt to destroy the flotilla collected in Boulogne, his watch was so vigilant that the boats never ventured from under the protection of their chains and batteries.

On the renewal of the war Nelson was at once sent out to the Mediterranean, where, with his flag in the *Victory*, he cruised for more than eighteen months in front of Toulon, drawing back occasionally to Madalena for water and refreshment. During one of these absences, in March 1805, the French fleet put to sea under the command of Vice-admiral Villeneuve, and got clear away to Gibraltar, to Cadiz, and to Martinique, where they expected to be joined by the fleet from Brest.

Nelson, however, though delayed for six weeks by his ignorance of where Villeneuve had gone, was only twenty days behind him; and Villeneuve, deceived as to the English numbers, and unwilling to risk an engagement which might frustrate his ulterior object, hastily returned to Europe. Nelson again followed, again outsailed his enemy, and arrived off Cadiz some days before the French approached the shores of Europe. Then, conceiving that Villeneuve's aim might be to overpower the fleet off Brest, he went north and reinforced it with most of his ships, returning himself to England. It was but for a few weeks. Within a fortnight it was known that Villeneuve had gone to Cadiz, and Nelson was ordered to resume the command. He did so on 25th September, and for the next month kept a close watch on the port, while his fleet was being gradually increased in numbers. He was especially desirous that he should have sufficient force. What he wanted was not merely an honourable victory gained by an inferior fleet, but the annihilation of the enemy. Villeneuve was meantime urged by positive and repeated orders to put to sea, and on 20th October, having learned that some of the English ships had gone to Gibraltar, he reluctantly came out. Of French and Spanish ships combined there were with him thirty-three; with Nelson there were twenty-seven.

At daybreak on the 21st the two fleets were in presence of each other off Cape Trafalgar, and Nelson, who several days before had given out and explained his plan of attack, at once made the signal to bear up towards the enemy. The wind was very light, and it was noon before the lee division of the fleet, under Collingwood in the *Royal Sovereign*, broke through the rear of the Franco-Spanish line. Nelson, with the other division, had reserved to himself the duty of over-awing the van, till, convinced that they had no immediate intention of turning to support their rear, he bore up and threw himself on their centre. As the *Victory* passed astern of Villeneuve's flagship, she fell foul of the *Redoutable* of seventy-four guns, and her quarter-deck became exposed to the musketry fire from the *Redoutable's* tops. Nelson, while standing speaking to Captain Hardy, fell mortally wounded by a shot on the left shoulder, which, striking obliquely downwards, passed through the spine. He was carried below, and died some three hours later, just as the battle ended in the decisive victory of the English. The enemy's fleet was annihilated.

Nelson's body was brought home, and, after lying in state at Greenwich, was interred with much pomp in the crypt of St Paul's. In the cathedral above a gorgeous monument has been erected to his memory, and numerous others throughout the land bear witness to the deep feeling which his splendid services awakened.

His Life by Clarke and M'Arthur (2 vols. 1809) is written with more credulity than critical accuracy. Southey's famous Life (2 vols.) dates from 1813. The best record of Nelson's services is his *Dispatches and Letters*, edited by Sir N. Harris Nicolas (7 vols. 8vo, 1844-46); there are a selection from the *Letters and Dispatches* (1886) and a Life (1896) by the author of the present article (Sir J. K. Laughton); a Life by Admiral A. T. Mahan (1897; revised 1899); and the *Last Diary* (ed. G. Hudson, 1917). See also Jeaffreson's *The Queen of Naples and Lord Nelson* (1889) and *Lady Hamilton and Lord Nelson* (1888); and Mrs Gamlin's *Nelson's Friendships* (1899).

Nelson, ROBERT, was born in London on 22d June 1656, a rich Turkey merchant's son, and, after a brief space at St Paul's school, removed with his widowed mother to Dryfield in Gloucestershire, where he was brought up by Dr George Bull.

In 1680, the year of his election to the Royal Society, he set out with Halley on a twenty months' tour in France and Italy, returning from Italy with Lady Theophila Lucy (1654-1705), a widow, and daughter to the Earl of Berkeley, who in 1683 became his wife, and who soon after was converted to Catholicism by Cardinal Howard and Bossuet. Her ill-health had taken them again to Italy at the time of the Revolution; but Nelson was from the first a (passive) Jacobite, and on his return to England in 1691 he joined the Nonjurors. He was received back into the Established Church in 1710, though he still would not join in the prayers for Queen Anne; and he died at Kensington on 16th January 1714. One of the earliest members of both the S.P.C.K. and S.P.G., he was author of five devotional works, the best known *Festivals and Fasts* (1703).

See Lives by Teale (1840-46) and C. F. Secretan (1860).

Nelson River issues from the north end of Lake Winnipeg in Canada, and, after a north-easterly course of 400 miles through Manitoba, falls into Hudson Bay at York Factory, in the estuary of Port Nelson. It is navigable for 127 miles from its mouth, though as yet only some 70 or 80 miles for large steamers. See also HUDSON BAY.

Nelumbo (*Nelumbium* or *Nelumbo*), a genus of aquatic Nymphæaceæ with exalbuminous seeds and distinct carpels, the latter buried in cavities of a large fleshy receptacle. The flowers, remarkable for their beauty, and the leaves are very like those of water-lilies. Much developed and widespread in Tertiary times, the genus has but two survivors. *Nelumbium nuciferum* (or *Nelumbo nucifera*), found in the warm parts of Asia, the north of Africa, and the north of Australia, is the Egyptian Bean of Pythagoras, the *Lotus* and *Tamara* of the Hindus, and the *Lien-Hoa* of the Chinese. For the ancients it was an emblem of fertility; with it the Egyptians decorated the heads of Isis and Osiris. The Hindus hold it sacred, and with them it is the floating shell of Vishnu and the throne of Brahma. The Tibetans embellish their temples and altars with it. It is also much esteemed and cultivated in the East for its seeds, roots, leaf-stalks, and flower-stalks, all of which are eaten. It has been used as food by the Egyptians from remote antiquity. The seeds are in size and shape like acorns, with a taste more delicate than that of almonds. The

root contains much starch, and a kind of arrowroot may be obtained from it; and powdered it makes excellent soup with milk or water. Great quantities are pickled with salt and vinegar, and eaten with rice. The flowers are generally rose-coloured, seldom white. The

ancient Egyptian mode of sowing this plant, by enclosing each seed in a ball of clay and throwing it into the water, is practised at the present day in India.—*N. luteum* is a North Amer-

Nelumbium luteum.

ican species, with yellow flowers, extending almost as far north as Philadelphia. The farinaceous roots are agreeable when boiled.

Nemathelmia, or NEMATHELMINTHES (Gr. *nēma*, 'a thread,' and *helmins*, 'an intestinal worm'), a general name applied to the threadworms or nematodes, such as *Ascaris* (q.v.), *Guinea-worm* (q.v.), *Trichina* (q.v.), to the somewhat distinct Gordiidae or hair-eels, and to the more remotely allied Acanthocephala or *Echinorhynchus* (q.v.).

Nematodes. See THREADWORMS, PARASITIC ANIMALS.

Nemea, anciently the name of a deep and well-watered valley of Argolis, in the Peloponnesus, between Cleonæ and Phlius. It lies north and south, and is from two to three miles long and more than half a mile broad. It possessed a sacred grove, with a magnificent temple of Zeus, and was celebrated for the games called the *Nemean Games*, one of the great national festivals of the Greeks. See ATHLETIC SPORTS.

Nemertea, an important class of 'worms,' the members of which are mostly marine. They are unsegmented, covered with cilia, and often brightly coloured. Their habitat is usually in sand or mud, but many are able to swim, while a few are commensals. In diet they seem to be mainly, if not wholly, carnivorous. The body is very extensible, and in *Lineus maximus* may measure 15 feet in length. Most of them break readily and even spontaneously, the fragments being in some cases able to form a fresh head and body. Among their remarkable characters may be noted the presence of a long protrusible offensive proboscis which lies quite apart from the gut in a special sheath along the back, and the occurrence of two curious ciliated pits, perhaps respiratory in function, opening on the sides of the head, and sometimes reaching as far inwards as the brain. Two nerve cords extend from the brain along the sides of the body, occasionally approaching one another ventrally or even dorsally. The sexes are separate, and there is frequently a remarkable metamorphosis in development. According to Professor Hubrecht, the nemerteans exhibit in the proboscis, its sheath, and the two head-slits distinct affinities with vertebrates.

Nemesis, according to Hesiod, the daughter of Night, was originally the personification of the moral feeling of right and a just horror of criminal actions—in other words, of the conscience. Afterwards, when an enlarged experience convinced men that a divine will found room for its activity amid the little occurrences of human life, Nemesis came to be regarded as the power who constantly preserves or restores the moral equilibrium of earthly affairs—preventing mortals from reaching that excessive prosperity which would lead them to forget the reverence due to the immortal gods, or visiting them with wholesome calamities in the midst of their happiness. Hence originated the latest and loftiest conception of Nemesis, as the being to whom was entrusted the execution of the decrees of a strict retributive providence—the awful and mysterious avenger of wrong, who punishes and humbles haughty evil-doers in particular. Nemesis was thus regarded as allied to Atë (q.v.) and the Eumenides (q.v.).

Nemi, LAKE OF, an extinct crater, 20 miles S. of Rome, accounted for its beauty the gem of the Alban Mountains. There was here, 3 miles from the ancient city of Aricia, a famous temple of Diana. Renan's *Prêtre de Nemi* (1885) gave the place renewed interest; and Sir J. G. Frazer's *Golden Bough* (1890; 3d ed. 1911-15), a profound study in comparative religion, starts from an exposition of the

strange custom described by Strabo and Pausanias as still in force in their days, that the high-priest, who was called 'King of the Grove' (*Rex Nemorensis*), was a fugitive slave who had secured the post by killing his predecessor, thenceforward inheriting the like risks.

Nemophila, a genus of herbaceous annuals belonging to the Hydrophyllaceæ, with pinnatifid leaves and conspicuous flowers. Natives of North America, they are cultivated in European gardens, the *N. insignis* being prized for its showy flowers, blue with a white centre.

Nemours, an ancient town of 5000 inhabitants in the French department of Seine-et-Marne, 40 miles SE. of Paris by rail, gave a ducal title to the second son of Louis-Philippe (1814-96).

Nenagh, a market-town of County Tipperary, 28 miles NE. of Limerick; pop. 4800.

Nendrum, a monastery on Mahee Island, in Strangford Lough, believed to have been founded about 450 A.D. The site had been forgotten, but excavations have revealed remains of early Christian and pagan times. See Lawlor, *Monastery of St Mochaí* (1925).

Nennius, the reputed author of a *Historia Britonum*, evidently of Cymric origin. It gives the mythical account of the origin of the Britons, the Roman occupation, the settlement of the Saxons, and closes with the twelve victorious battles of King Arthur. The manuscripts, of which none is earlier than the end of the 10th century, are so confused and so largely interpolated that many critics were inclined to deny all authenticity to it. But Zimmer showed that though the longer prologue and other parts are to be rejected, the nucleus is the work of a Welshman of the close of the 8th century, whose own authority is slight. The most important part is the *Genealogie Saxonum*, based on an earlier Strathelyde writer. For the rest he follows Gildas, Eusebius, Prosper of Aquitaine, and three or more Irish authors. The text was edited by Stevenson for the English Historical Society in 1838; but the best edition is Mommsen's (in *Mon. Germ. Hist.*, xiii. 1898). See De la Borderie, *Historia Britonum* (Paris, 1883); works by Skene and Rhys; Zimmer, *Nennius Vindictus* (1893); Lloyd, *History of Wales* (1911); and Williams, *Christianity in Early Britain* (1912).

Neon (Ne; atom. number 10), a gas discovered in air by Sir W. Ramsay and Mr Travers in 1898, and shown by Sir J. J. Thomson, by his positive ray method, in 1913 to be a mixture of two isotopes, of atomic weights 20 and 22. See ARGON, ATMOSPHERE.

Neoplatonism, the last form of Hellenic philosophy, the system of an illustrious succession of ancient philosophers who claimed to found their doctrines and speculations on those of Plato. Strictly speaking, however, the Platonic philosophy expired with Plato's immediate disciples, Speusippus and Xenocrates. Neoplatonism is an attempt to combine Plato's doctrine of the Ideas, developed by Aristotle, and supplemented with an ethical system akin to that of the Stoics, with the oriental doctrine of Emanation; it does for Hellenism something like what Philo did for Judaism. Such amalgamation came about most naturally in Alexandria. Placed at the junction of two continents, Asia and Africa, and close to the most cultivated and intellectual

regions of Europe, that celebrated city naturally became a focus for the chief religions and philosophies of the ancient world. Here the East and the West, Greek culture and oriental enthusiasm, met and mingled; and here Christianity sought a home, and by the liberality of its sympathies strove to quell the myriad discords of Paganism.

Authorities have differed as to how much should be included under the term Neoplatonism. By some it is used to designate the whole new intellectual movement proceeding from Alexandria, comprising, in this broad view, the philosophy of Philo-Judæus and of Numenius the Syrian; of Christian Fathers like Clemens Alexandrinus and Origen; of the Gnostics; and of Ammonius Saccas and his successors. But the best authorities restrict the application of the term to the fourth of these series. Plotinus, its real founder, resuscitated Plato; Proclus gave the world another Aristotle; in the person of Julian the Apostate Neoplatonism became master of the world, and for three centuries it was a formidable rival to Christianity. The Neoplatonists aimed at constructing a religion on a basis of dialectics. They strove to attain a knowledge of the Highest, and the way in which they endeavoured to accomplish this was by assuming the existence of a capacity in man for passing beyond the limit of his empirical knowledge, and acquiring an intuitive knowledge of the absolute, the true—that which is beyond and above the fluctuations and dubieties of ‘opinion.’ This impersonal faculty is called *Ecstasy*. By means of it man—ceasing, however, to be individual man—can identify himself with the Absolute (or Infinite). Plotinus, in fact, set out from the belief that ‘philosophy’ is only possible through the identity of the thinker, or rather of the subjective thought, with the thing thought of, or the objective thought. This intuitive grasp or ‘vision’ of the Absolute is not constant; we can neither force nor retain it by an effort of will; it springs from a divine inspiration and enthusiasm higher and purer than that of poet or prophet, and is the choicest ‘gift of God.’

The god of Plotinus and the other Alexandrians is a mystical Trinity. The Divine Nature contains within it three Hypostases (Substances); its basis, if we may so speak, is Unity or Primitive Light. This Unity is not itself any *thing*, but the principle of all things; it is absolute good, absolute perfection; and, though it is utterly incapable of being conceived by the understanding, there is that in man which assures him that it—the incomprehensible, the ineffable—*is*. From Unity, as the primordial source of all things, emanates Pure Intelligence (*Nous*), its reflection and image, that by which it is intuitively apprehended; from Pure Intelligence, in turn, emanates the ‘Soul of the World,’ whose creative activity produces the souls of men and animals, and ‘Nature;’ and finally, from Nature proceeds ‘Matter,’ which, however, is subjected by Plotinus to such refinement of definition that it loses all its grossness—though he is no dualist, and glories in the beauty of the world. Unity, Pure Intelligence, and the World-Soul thus constitute the Plotinian Triad, with which is connected, as we have seen, the doctrine of an eternal Emanation. Human souls, whose source is the Pure Intelligence, are—by some mysterious fate—imprisoned here in perishable bodies, and the higher sort are ever striving to reascend to their original home.

The most distinguished pupil of Plotinus was Porphyry, who mainly devoted himself to expounding and qualifying the philosophy of his master. In him we see for the first time the presence of a distinctively anti-Christian tendency. Neoplatonism, which can only be properly understood when we regard it as an attempt to place

Paganism on a philosophical basis—to make the Greek religion philosophical, and Greek philosophy religious—did not *consciously* set out as the antagonist of Christianity. Neither Ammonius Saccas nor Plotinus assailed the new faith; but as the latter continued to grow, and to attract many of the most powerful intellects of the age into its service, this latent antipathy began to show itself. Porphyry wrote against Christianity; Iamblichus, the most noted of his pupils, did the same. The latter also introduced a theurgic or ‘magical’ element into Neoplatonism, teaching, among other things, that certain mystical exercises and symbols exercised a supernatural influence over the divinities. Magic and spiritualism are always popular, and it is therefore not wonderful that Iamblichus should have had numerous followers. Aedesius succeeded to his master’s chair. From the school of one of his disciples, Maximus, came the Emperor Julian, whose patronage for a moment shed a gleam of splendour over Neoplatonism, and seemed to promise it a universal victory.

After a succession of able but not always consistent teachers, among whom is to be reckoned the noble Hypatia, we reach Proclus, the last great Neoplatonist, who belongs to the 5th century, a man of prodigious learning, and of an enthusiastic temperament, in whom the pagan-religious, and consequently anti-Christian, tendency of the Neoplatonic philosophy culminated. His ontology was based on the Triad of Plotinus, but was considerably modified in detail; he exalted ‘Faith’ above ‘Science’ as a means of reaching the Absolute Unity; was a believer in Theurgy, and so naturally laid great stress upon the ancient Chaldean oracles, Orphic hymns, mysteries, &c., which he regarded as divine revelations, and of which he considered himself—as, indeed, he was—the last great ‘interpreter.’ His hostility to the Christian religion was keen; in its success he saw only the triumph of a vulgar popular superstition over the refined and beautiful theories of philosophy; it was as if he beheld a horde of barbarians defacing the statues and records of the Pantheon. The disciples of Proclus were numerous, but not remarkable for talent. Perhaps the ablest of his successors was Damascius, in whose time the Emperor Justinian, by an arbitrary decree, closed the schools of the heathen philosophers. Neoplatonism soon ceased to exist as a system; but it served as a schoolmaster to bring the mediæval thinkers to Plato and Aristotle, it served as the nurse of Christian mysticism, and it had helped to mould the mind of Augustine. From a scientific point of view it was retrogressive, perverse, absurd; yet in the moral and religious sphere it maintained a high and holy ideal, and fostered a firm belief in that which is above the empirical.

See T. Whittaker, *The Neo-Platonists* (1918); Zeller, *Ueberweg*, and other historians of philosophy; Herzog-Hauck *Realencyklopädie*; the church histories; Kingsley, *Alexandria and her Schools*, and *Hypatia*; Bigg, *Christian Platonists of Alexandria* (1885); Simon, *Histoire de l’École d’Alexandrie* (1845); Vacherot, *Histoire critique de l’École d’Alexandrie* (1851); and the articles in this work on PLATO, STOICISM, PHILO, ORIGEN, Gnostics, Plotinus, Porphyry, Iamblichus, Proclus.

Neo-Pythagoreanism stood to Pythagoras somewhat as Neoplatonism did to Plato, and was an Alexandrian development under oriental influences. It originated in the first half of the century before Christ, and was accordingly the predecessor of Neoplatonism. Neo-Pythagoreans may be divided into two groups, according as their aims were mainly practical—the purification and ennobling of life by asceticism, including theurgy, or more modestly metaphysical—basing their views on the Pythagorean theory of numbers (see PYTHA-

GORAS). Of the former school Apollonius (q.v.) of Tyana is the most conspicuous example; of the latter, Moderatus of Gades, Nicomachus of Gerasa (2d century A.D.), Archytas (q.v.), and Sextius. See the works cited at NEOPLATONISM.

Neozoic (Gr., 'new life'), a term introduced by Edward Forbes to include all the strata from the Trias to the most recent deposits. Few geologists have adopted the term; the systems in question being generally divided into the groups of Secondary or Mesozoic, Tertiary or Cainozoic, and Quaternary or Post-Tertiary.

Nepal, an independent kingdom of India, lying on the southern face of the Himalayas, is bounded on the N. by Tibet, on the S. and W. by the United Provinces and Bengal, and on the E. by Sikkim, a protected state. Long. 80° 6'—88° 14' E. It is 512 miles in length, by 70 to 150 in breadth. Area, 54,000 sq. m.; pop. of about 5,500,000. The northern parts of the state embrace the main range of the Himalayas (q.v.), with its offset spurs, on which stand the great peaks of Everest, Diwalagira, &c. On the south of the state lies the Terai. The intervening territory consists of mountain-ridges, embracing several valleys drained by the Kurnali, Gandak, Kosi, and other rivers. The climate of course varies greatly according to the altitude; the principal valley, in which stands the capital Khatmandu (q.v.), has a climate like that of southern Europe. The soil is very fertile, in some districts producing three crops in the year. The hillsides are terraced and the land is irrigated. Rice, opium, rape, linseed, tobacco, and various cereals and pulses are the more important products. Several minerals, as copper, iron, sulphur, exist, but are little worked. The forests contain valuable timber trees. Nepal has extensive trading relations with the provinces of British India and with Tibet. The valleys are inhabited by numerous different hill-tribes, partly aboriginal, partly of Mongolian or Chinese descent; but the dominant race are the Gurkhas (q.v.), whose ancestors came to the Himalayan slopes from Rajputana in the 12th century, though it was not until 1769 that they made themselves masters of Nepal. They rapidly subdued the hill-valleys to east and west of them, and, after a war with China (1789-92), on account of Tibet, in which the Gurkhas were worsted, and a period of great internal disorder, Nepal came into conflict with the Indian Government. War followed; in 1815 Sir David Ochterlony defeated the Gurkha armies in the west, and peace was agreed to; but, the treaty not having been signed by the king of Nepal, a British force, 33,000 strong, advanced in the succeeding year to within three days' march of Khatmandu, and compelled the Gurkhas to sign the treaty. Since that they have ceased their encroachments on British territory, and during the Mutiny voluntarily sent to the assistance of the British a force which rendered useful service in the reduction of Oudh. The real ruler of the country is the prime-minister; Sir Jang Bahadur held this office from 1846 to his death in 1877, and was succeeded by his son. But he was slain and supplanted by Bir Shamsheer, the head of a rival faction, in 1885. Bir Shamsheer's brother, Chandra Shamsheer, became minister in 1901, and attended the coronation durbar at Delhi as a guest of the Government of India in 1903. A new treaty of friendship was concluded between the governments of Nepal and Great Britain in December 1923.

Nepenthes. See INSECTIVOROUS PLANTS.

Nepheline (Gr. *nephelē*, 'a cloud,' in allusion to the mineral becoming cloudy when immersed in a strong acid), a rock-forming mineral of some importance. It is colourless, white or yellowish, and usually crystallises in hexagonal prisms with

various modifications. It has a hardness of 5½ to 6, and sp. gr. of 2½ or thereabouts. It occurs in igneous rocks rich in soda but with medium to low percentages of silica. Thus it is an essential constituent of phonolite, nepheline tephrite, and nepheline basalt. These rocks are found, for example, among the products of igneous activity of Carboniferous and Permian times in the midland valley of Scotland, as in the phonolite of Traprain Law and the nepheline basalt of Chapel Ness, Fife. Elæolite (Gr. *elaion*, 'oil') is a variety of nepheline with a greasy lustre, which seldom assumes a crystalline form. It is dark greenish, gray, or brown in colour, and appears to occur only in plutonic rocks, as in the syenites of Frederiksvärn and Laurvig in Norway.

Nephelium. See LITCHI.

Nephrite, a name given to compact, fine-grained varieties of tremolite and actinolite which are minerals belonging to the group of monoclinic amphiboles. Tremolite is a calcium-magnesium silicate, actinolite a calcium-magnesium-iron silicate; the former is white, the latter green in colour. Like the pyroxene, jadeite, with which it is often confused, nephrite is exceedingly tough. It has a splintery fracture and a glistening lustre. The hardness ranges from 6 to 6½, and the density from 2.96 to 3.1. See JADE.

Nephritis (Gr. *nephros*, 'kidney'), inflammation of the Kidneys (q.v.).

Nepomuk (or POMUK), JOHN OF, the patron saint of Bohemia, who is honoured as a martyr of the seal of confession, was born at Pomuk, a few miles SE. from Pilsen, about 1330. Having studied at the university of Prague and taken holy orders, he held various ecclesiastical offices in Prague, and was appointed confessor to Sophia, wife of King Wenceslaus IV. For refusing to betray to this monarch the confession of the queen John was put to the torture, then tied hand and foot, and flung into the Moldau, in March 1383. His memory was cherished with peculiar affection by the Bohemian people, and in 1729 he was canonised by Pope Benedict XIII. His memory is celebrated on 16th May. By some historians two distinct personages of the same name are enumerated—one, the martyr of the confessional, the other, a victim to the simoniacal tyranny of Wenceslaus; but the identity of the two is sustained by Palacky, *Geschichte von Böhmen*, iii. 62. In 1855 Abel tried to prove that John of Nepomuk was a merely Catholic transformation of the people's darling, the heretical John Huss. See Wratistaw's *Life, Legend, and Canonisation of St John Nepomucen* (1873).

Nepos, CORNELIUS, a Roman historical writer, was a native of Pavia, as Mommsen thinks, of Hostilia (now Ostiglia), as its citizens believed they proved by erecting a statue in 1868. He was the contemporary and friend of Cicero, Atticus, and Catullus, and was probably still alive in 25 or 24 B.C. The ancients ascribed to him the following works: *Chronica*, *Exemplorum Libri*, *Lives of Cato and Cicero*, and *De Viris Illustribus*. The last is supposed to have consisted of sixteen books, but only twenty-five brief biographies of warriors and statesmen, mostly Greeks, have survived. These biographies are untrustworthy as history, but are written in a clear and elegant style, although affected archaisms and euphuistic mannerisms are not unfrequent. Until the middle of the 16th century they were generally ascribed to Æmilius Probus (4th century); but in 1569 the famous Dionysius Lambinus claimed them as part of the lost work of Cornelius Nepos. Other good editions are those of Fleckeisen (1884), Browning and Inge (1888), Lindsay (N.Y., 1895), and Nip-

perdey (10th ed. 1896). See FREUDENBERG'S *Questions historice* (1839).

Nepotism (Ital. *nepote*, 'a nephew'), a word used to signify the system or custom practised by several popes subsequent to Innocent VIII. of granting high honours, dignities, offices, pensions, and the like to their family relations, generally their nephews, altogether irrespective of merit.

Neptune, the Italian god of the sea. Attempts have been made to show that his worship goes back to Aryan times, by identifying his name with the Sanskrit and Iranian Apām Napāt, 'offspring of the water.' But this is one of those unfortunate identifications which show that comparative mythologists are not always comparative philologists. Further, as there is nothing whatever to make it in the least probable that Neptune was ever anything but a sea-god, and as the primitive Aryans were not acquainted with the sea, it is evident that he cannot have been an Aryan deity. Indeed, as it was not until after the Italians had entered Italy that they became at all familiar with the sea, it was probably not until after they had settled in Italy that they made acquaintance with Neptune. Nor in all probability was he their own invention. We may conjecture that he was borrowed by them from the Etruscans, a maritime nation, who worshipped as their sea-god Nethuns or Nethunus. Had the Italians never come in contact in historical times with the Greeks, Nethunus or Neptunus would have remained a mere abstraction, like all other Italian deities, who were rather *numina* than personal beings. But communication with Greece resulted in the Italians identifying their god of the sea with Poseidon (q.v.), the Greek god of the sea.

Neptune. See PLANETS.

Neptunist Theory. See GEOLOGY.

Nerbudda (more correctly NARBADA), a river of India, rises on the Amarkantak plateau, 3493 feet above sea-level, in 22° 41' N. lat., 81° 49' E. long., and flows west, through the Central Provinces, past Jabalpur (190 miles from its source), through the great depression between the Vindhya Mountains on the north and the Satpura Mountains on the south, known as the Valley of the Nerbudda, and reaches the Gulf of Cambay half-way between Baroda and Surat. It has a total length of 800 miles, and drains 36,400 sq. m. It is navigable as far as Broach, 30 miles from its mouth. The river ranks as a sacred stream in the eyes of the Hindus; some have held it likely to supersede the Ganges in sanctity. It is regarded as a meritorious act to walk from the sea to its source and back again alongside the river.

Nerchinsk. See NERTCHINSK.

Nereid. See NYMPH.

Nereis, a common genus of marine worms or Chaetopods, the members of which live in the sand or more freely in the sea. See CHAETOPODS, and WORMS.

Neri, ST PHILIP, the founder of the Congregation of the Oratory, was born at Florence, 21st July 1515. His uncle wished to make him his heir; but the youth, abandoning all worldly pursuits, left his family and betook himself in his eighteenth year to Rome. A Florentine gentleman gave him a small room as a lodging and a daily allowance of meal. Philip spent most of his time in visiting the sick, in instructing the poor and ignorant, and in solitary prayer in the catacombs. It was not till 1551 that he was persuaded to become a priest. He now took up his quarters in the little church of S. Girolamo, and, gathering round him a number of disciples, started the exercises of devotion which made his name famous. At

first these simple services or prayer-meetings were held with a few young men in his own room. In 1558 they were transferred to an oratory which he was permitted to build over the nave of the church. These daily services, which were a great novelty at the time, consisted of three sermons of about half an hour's duration, delivered in a familiar style, and interspersed with vernacular hymns, reading, and prayers. The preachers were for the most part laymen. During the day Philip took many of his penitents round the hospitals. His object was to make religion attractive, especially to the young. At the carnival or in holiday seasons he instituted musical entertainments and the acting of religious dramas. At other times he took numbers of men in procession through the streets on a pilgrimage to the seven churches, alternately singing hymns and praying in silence. This work was more fully developed in Rome, whither in 1564 Neri was summoned by the Florentines settled there, who put under his charge their church of San Giovanni dei Fiorentini, and beside it built for him in 1574 an oratory or mission-hall. Having had some of his companions ordained priests, he established them here as a community. One of these was Cesare Baronio, the historian of the church, and afterwards cardinal. Ten years later the community, now much increased in number, moved to S. Maria in Vallicella, on the site of which Philip built a larger church, known as the Chiesa Nuova, or New Church. Here the institute of the Oratory received the formal approbation of the pope, and here Philip died, 25th May 1595.

A notable phenomenon connected with his life is one which is to Philip what the stigmata were to Francis of Assisi—a strange palpitation of the heart and fracture of the ribs attributed to the supernatural effects of divine love—which came upon him suddenly one day at prayer in the catacombs. Philip was canonised with Ignatius Loyola and others in 1622.

Philip's literary remains consist of a few letters (8vo, Padua, 1751) and some sonnets printed in the collection of the *Rime Oneste*. See the lives by Gallonio (1600), and by Bacci (1622; trans. by Faber, 1849); *The Spirit and Genius of St Philip Neri*, by F. W. Faber (1850); the life by Mrs Hope (1859), and that by Archbishop Capececiatello (1879, 1884; trans. 1882, 1894); and the articles in Wetzer and Welte and in the *Catholic Encyclopedia*. For the Congregation of the Oratory in Italy, France, and England, see ORATORY, NEWMAN, FABER.

Néris-les-Bains. See MONTLUÇON.

Nero, the last of the Cæsars and the mystic antichrist of primitive Christian tradition, Roman emperor from 54 to 68 A.D., was born at Antium, on the coast of Latium, 15th December 37, and was the son of Cn. Domitius Ahenobarbus and of the younger Agrippina, the daughter of Germanicus Cæsar, and sister of Caligula. His mother became the wife of the Emperor Claudius, who adopted him (50), his name, originally L. Domitius Ahenobarbus, being changed to Nero Claudius Cæsar Drusus Germanicus. After the death of Claudius (54) the Prætorian Guards, at the instigation of Afranius Burrus, their prefect, declared him emperor, instead of Claudius's son Britannicus, and their choice was acknowledged both by the senate and by the provinces. His reign began with the semblance of moderation and good promise, under the guidance of Burrus and his tutor Seneca the philosopher; but the baleful influence of his mother, together with his own moral weakness and sensuality, frustrated their efforts, and he soon plunged headlong into debauchery, extravagance, and tyranny. He caused the young Britannicus, the son of Claudius, to be treacherously poisoned in order to please his infamous and ambitious mistress Poppæa Sabina. To marry her

he divorced and put to death his neglected wife Octavia, the sister of Britannicus. The affairs of the empire were at this time far from tranquil. In 61 an insurrection broke out in Britain under Queen Boadicea, which was suppressed by Suetonius Paulinus. Next year saw an unsuccessful war against the Parthians in Armenia. At home the emperor was lampooned in verse; and even Seneca, though no rigid moralist out of his books, thought it only decent to remove from court. In July 64 occurred a great conflagration in Rome, by which two-thirds of the city was reduced to ashes. Nero himself is stated by all authorities later than Tacitus to have been the incendiary. But he found a convenient scapegoat in the mysterious sect of the Christians, many of whom were put to death with unheard-of cruelties, such as being wrapped in cloth steeped with pitch, and set on fire in the imperial gardens. Moreover, he rebuilt the city with great magnificence, and reared for himself on the Palatine Hill a splendid palace, the famous 'golden house,' and in order to provide for this expenditure and for the gratification of the Roman populace by spectacles and distributions of corn Italy and the provinces were plundered without ruth. A conspiracy against Nero in the year 65 failed, and Seneca and the poet Lucan fell victims to his vengeance. In a fit of passion he murdered his wife Poppæa, by kicking her when she was pregnant. He then offered his hand to Antonia, the daughter of Claudius, but was refused, whereupon he caused the too fastidious lady to be put to death, and married Statilia Messallina, after putting her husband to death. He also executed or banished many persons highly distinguished for integrity and virtue. His undignified vanity led him to seek distinction as a poet, a philosopher, an actor, a musician, and even a charioteer, and he received sycophantic applause, not only in Italy, but in Greece, to which, upon invitation of the Greek cities, he made a visit in 67. But in 68 the Gallic and Spanish legions, and after them the Prætorian Guards, rose against him to make Galba emperor, and Nero fled from Rome to the house of a freedman, Phaon, about four miles distant. The senate now declared him an enemy of his country, and the trembling tyrant saved himself from execution by suicide, 11th June 68. His last words throw light on his pitiful vanity and on the cruel irony of fate that placed him on a throne—'What an artist is lost in me!'

Neroli, OIL OF. See **ORANGE**.

Nertchinsk, a town of eastern Siberia, on the Nertcha, a tributary of the Shilka (which is a head-stream of the Amur), 875 miles E. of Irkutsk. The district of which it is the centre yields silver, lead, zinc, tin, and gold; and the town is a trading centre for Russians, Mongols, Turkomans, and Tunguses, exchanging tea, gunpowder, tobacco, and furs. Pop. 10,000.

Nerthus. See **HERTHA**.

Neruda, JAN. See **CZECHOSLOVAKIA** (*Literature*).

Neruda, WILMA. See **HALLÉ**.

Nerva, M. COCCÆUS, a Roman emperor, elected by the senate after the murder of Domitian, 18th September 96 A.D. He was born in 32, of a family belonging to Narnia, in Umbria, and twice held the honour of consulship before his election to the dignity of emperor. He displayed great wisdom and moderation, rectified the administration of justice, and diminished the taxes; but find-

ing himself, on account of his advanced age, not vigorous enough to repress the insolence of the Prætorian Guards, he adopted M. Ulpius Trajanus, then at the head of the army of Germany, who succeeded him on his death, 27th January 98.

Nerval, GÉRARD DE, the adopted name of Gérard Labrunie, one of the most attractive but ill-starred figures among the French Romanticists, was born at Paris, May 21, 1808, son of an officer in the Grand Army. He was educated along with Gautier at the Lycée Charlemagne, and early took to letters, publishing at twenty a translation of *Faust* which pleased Goethe, and gave his choruses to Berlioz. Desultory work, a love-affair cut short by death, fits of restless travel, of dissipation, and of gloom that at times deepened into mental darkness, and at last death, almost certainly by his own hand, 25th January 1855, sum up the wretched story of his life. He moved in a romantic dream-world all his days, squandered money when he had it prodigally upon *bric-à-brac*, read deeply in Greek, Italian, German, English, and Arabic, and wandered carelessly over Italy, Germany, Greece, Syria, Palestine, and Egypt. Gérard de Nerval wrote admirably alike in prose and verse, his style ever delicate, natural, and original, informed with a subtle personal charm of a quite remarkable character. But his travels, criticism, plays, and poems, good literature as they are, are far less interesting than his *Aurélien, ou le Rêve et la Vie* (1855), an experience of his own madness. 'This strange work,' says Andrew Lang, 'does for insanity what the *Dream of Gerontius* has done for death.' In *Les Illuminés, ou les Précurseurs du Socialisme* (1852), he discusses the mysticism of certain highly endowed men in its relation to mental alienation. But his most delightful work will be found in his fantastic short tales, which have an exquisiteness of their own that approaches near perfection. These are the *Contes et Facéties* (1852), and the semi-autobiographic series of *Filles du Feu*, containing *Sylvie, Angélique, Jenny, Octavie, Isis, Emilie, Corilla* (1856). Another book of singular interest is the mélange entitled *La Bohème Galante*. Some of his most charming poems are graceful adaptations of French peasants' folk-songs, the beauty of which he had ears to hear.

His works were collected in 1868. See Andrew Lang in *Fraser* (1873); and works by Ferrières (1906) and Marie (1915).

Nervii, a powerful and warlike people of the ancient Gallia Belgica, whose territory stretched from the Sambre to the ocean, not subdued by Cæsar without an obstinate resistance.

Nervous Diseases. See articles in this work on Alcoholism, Aphasia, Apoplexy, Appetite, Brain, Chorea, Cretinism, Delirium, Delirium Tremens, Epilepsy, Headache, Hydrocephalus, Hypochondriasis, Hysteria, Insanity, Locomotor Ataxia, Meningitis, Myelitis, Neuralgia, Paralysis, Sciatica, Spinal Cord, Sunstroke, Tetanus, &c.

NERVOUSNESS is a term somewhat vaguely used, both popularly and by medical men, to express an unduly excitable condition of the nervous system, manifested by unusually ready manifestation of emotion—e.g. starting at slight causes—by morbid sensitiveness, by unreasonable apprehension, by trembling of muscles, and in many other ways. The condition may be natural, or produced by ill-health or acute disease. It is more common in children than in adults, and in the female sex than the male. Care should be taken to improve the general health by good nutrition, regulation of the bowels, open-air exercise, bathing, change of air and scene, and the ordinary tonic remedies; stimulants and drugs should be avoided save under the special direction of a medical man.

Nervous System, the mechanism by which an animal acquires a knowledge of the external world, and by means of which the great functions of the absorption of food, the elimination of waste products from the body, the respiration, circulation, and muscular action, are regulated and controlled. In its simplest form, in some of the lowest animals, it consists merely of nerve-fibres going to and from a small group of nerve-cells; but from this elementary condition there is an ever-increasing degree of complexity till its highest development, which alone is included in the following description, is reached in man. In the articles on Birds, Fishes, Reptiles, Mollusca, &c., will be found paragraphs on the nervous systems of the various classes of animals.

Fig. 1.

a, cerebrum; *b*, cerebellum; *c*, medulla oblongata; *d*, spinal cord, from which the spinal nerves arise; *e*, brachial plexus; *f*, sciatic nerve.

The nervous system is composed of a series of organs—nerve-cells, nerve-fibres, and nerve end-organs. The nerve-cells are situated for the most part in the brain and spinal cord, but also in other parts of the nervous system. Their function is either to receive, to send out, or to modify as they transmit, nervous impulses. The nerve-fibres transmit nerve impulses to and from the nerve-cells. For this reason groups of nerve-cells are often conveniently spoken of as nerve centres, their relation to the nerve-fibres being analogous to that of a telegraph-office to the wires connected with it. The end-organs are the special structures for receiving impressions, such as the various organs of special sense, smell, sight, hearing, taste, touch (see NOSE, EYE, EAR, TASTE, TOUCH), and for transforming outgoing impulses into muscular contractions or secretion, &c. The nerve-fibres thus connect either an end-organ with a nerve centre, or two nerve centres with each other. These three sets of organs, nerve centres, fibres,

and end-organs, are grouped into two great systems—the *cerebro-spinal* (fig. 1) and the *sympathetic* (fig. 10) system. The former is composed of the brain, spinal cord, and the cranial and spinal nerves respectively connected with them. The sympathetic system is formed by a double chain of small swellings, called ganglia, on either side of the front of the spinal column, and connected with each other, with the spinal nerves, and the internal organs by fine nerve-fibres (figs. 7 and 10).

The nerves are whitish cords varying greatly in size. They are composed of nerve-fibres which are bound together by fibrous tissue. This forms a sheath on the outside (the *perineurium*), and sends processes inwards between the individual nerve-fibres (fig. 4 shows a transverse section of part of a nerve, with the bundles of connective tissue passing inward). In the spinal cord and brain the nerve-fibres are held together by a special kind of connective tissue, called *neuroglia*.

Structure of Nerve-fibres.—A fibre from a spinal nerve has the following structure. In the centre is a very fine fibre or thread called the *axis cylinder*. This runs without any interruption along the whole length of the nerve. It can be traced into a nerve-cell at one extremity, and into an end-organ at the other; and there is reason to believe that it is really an outgrowth from a nerve-cell. It is the essential constituent of a nerve, that namely along which the nervous impulse travels. The axis cylinder is in its turn composed of still finer fibrillæ, which may break up into finer nerve-fibres. Except at its origin and termination, the axis cylinder is covered by a tubular membrane called the *medullary sheath*, or the white substance of Schwann, a whitish substance of a peculiar fatty nature. This is interrupted at intervals of about $\frac{1}{16}$ th of an inch by constrictions which (fig. 2) pass completely through its thickness. When a nerve is stained with nitrate of silver a black colour is formed at the intersections, and for a short distance along the axis cylinder (see fig. 3, where two are represented). These interruptions are called *nodes of Ranvier*, after their discoverer, and are supposed to allow of the percolation of lymph to nourish the axis cylinder. When a nerve

Fig. 2.

Small part of a nerve-fibre with axis cylinder, surrounded by medullary sheath. The primitive sheath passes over the constriction in the medullary sheath.

Fig. 3.

Nerve-fibres, stained with nitrate of silver, showing two nodes of Ranvier.

is divided transversely, and stained appropriately, the axis cylinder appears as a small point surrounded by a ring of the whitish medullary sheath (fig. 4). This sheath is enclosed by a continuous investment, the *primitive sheath*. This is colourless, and very delicate, and has a nucleus on its inner side corresponding to each segment of the medullary sheath. In the sympathetic system the medullary sheath is absent; while the fibres of the

brain and spinal cord retain the medullary sheath, but want the primitive membrane. The sympathetic fibres are often called gray or non-medullated; the others, white or medullated. The nerve-fibres in the limbs are about $\frac{1}{1000}$ th of an

Fig. 4.

inch in diameter; in the brain they may be nearly ten times finer.

Nerve-cells vary in size and form. Some are bipolar, others multipolar (fig. 5, A and C). Many, especially in the cortex of the brain, are pyramidal in shape (fig. 5, B), with fine processes, termed *dendrons*, coming off at various points and breaking up immediately into smaller branches ending in fine twigs, and one special branch which becomes the *axis cylinder process* of the nerve fibre, termed briefly

Fig. 5.—Nerve-cells:

A, from sympathetic ganglion; B, from cerebrum; C, from spinal cord; a.p., axis cylinder process.

the *axon*. The term *neurone* is applied to the complete nerve unit, i.e. the body of the cell and all its branches. Impulses reach a nerve-cell by the dendrons and pass out by the axon. Each neurone is anatomically independent of every other neurone; there is no true anastomosis of the branches from one nerve-cell with those from another, the arborisations interlace and intermingle, and nerve impulses are transmitted from one nerve unit to another through contiguous, but not through continuous, structures. This intermingling of arborisations is termed a *synapse*.

Fig. 6.

The various end-organs are described under the special sections. Fig. 6 shows the manner in which the fibres of a nerve end in a muscle.

The nerves arising from the brain are arranged

in twelve pairs. The first, or olfactory, is the nerve of smell. The second, or optic, is the nerve of sight. It arises from the retina, meets with its fellow in the optic chiasma, and is distributed half to each side of the brain, terminating partly in the corpora quadrigemina (for the reflex movements of the eye), and partly in the optic thalamus, passing thence to the occipital lobe of the cerebrum (for the sense of sight). The third or oculo-motor nerve arises under the corpora quadrigemina, and passes to all the muscles of the eye except two, which are supplied by the fourth and sixth pairs. The fourth nerve, arising immediately behind the third nerve, supplies the superior oblique muscle of the eye; while the sixth pair, arising from a nucleus near the middle of the floor of the fourth ventricle, supplies the external rectus muscle of the eye. The fifth pair has a very long origin from a point at the level of the third nerve down to the upper part of the spinal cord. It is the motor nerve to the muscles of mastication, and the sensory nerve to the face, front of the head, teeth, tongue, and is the nerve of taste of the anterior part of the tongue. It is this nerve which is concerned in neuralgia of the head and face and teeth. The seventh pair arises from the lower part of the pons Varolii (see BRAIN), and is the motor nerve to the facial muscles of expression. Injury to or disease of this nerve causes facial palsy, or Bell's paralysis. The eighth pair, or auditory nerve, supplies the internal ear. It is divided into two parts, one of which supplies the cochlea, and is the nerve of hearing proper, while the other supplies the semi-circular canals, and is concerned in the maintenance of the equilibrium of the body. The nerve arises from the lateral and posterior part of the pons Varolii and medulla oblongata. The ninth pair, or glosso-pharyngeal nerve, is the special nerve of taste, and supplies the hinder third of the tongue, with the taste bulbs of which it is connected. The tenth pair, or pneumogastric nerve, has a very wide area of distribution to the lungs, heart, stomach, &c.; it is partly motor and partly sensory in function. The eleventh pair, or spinal accessory nerve, is the motor nerve to the larynx, and to certain muscles in the upper part of the neck. These three nerves arise from a groove in the side of the medulla oblongata and upper part of the spinal cord. The twelfth pair, or hypoglossal nerve, is the motor nerve of the tongue. Its origin is near the floor of the fourth ventricle, close to the middle line, and it emerges from the anterior surface of the medulla oblongata in a shallow groove between the anterior pyramids and the inferior olivary body (see BRAIN).

The spinal nerves arise from the spinal cord in pairs, thirty-one in number, and are named according to their relation to the vertebrae—cervical, dorsal, lumbar, and sacral. Their mode of origin will be understood from fig. 7, which represents diagrammatically the first part of their course, and on one side their relations with the sympathetic system—C 1-8 represents the eight pairs of cervical nerves; D 1-12, the twelve dorsal pairs; L 1-5, the five lumbar pairs; S 1-6, the five sacral pairs and the coccygeal pair. Each spinal nerve arises by two roots, an anterior and a posterior (fig. 8, a and p; see also SPINAL CORD). These roots pass outwards, and unite before they leave the spinal canal. Before their union a small oval swelling is found on the posterior root, and is called its *ganglion*, g. The united nerve leaves the spinal canal by a small aperture between adjacent vertebrae. It almost immediately gives off a fine medullated nerve to its corresponding sympathetic ganglion, a branch which can be traced into one of the internal organs. It also receives from the ganglion a non-medullated or gray fibre, which is distributed to

the muscular coat of the blood-vessels, especially the arteries. The nerve thus altered passes outwards, dividing as it goes to send its ultimate branches into the fibres of the muscles, into the cells of the skin and connective tissues, tendons, and bones. In the dorsal region each nerve passes

to its distribution without entering into connection with its neighbours, but in the cervical, lumbar, and sacral regions the nerves split up and form new junctions with each other, or *plexuses* as they are called. (These are indicated in fig. 1, and on the right-hand side of fig. 7, but the detailed description of them is impossible within the limits of this article.)

Functions of the Spinal Nerves.

—Sir Charles Bell discovered that division of the anterior roots was followed by loss of power of voluntary motion, and that division of the posterior roots destroyed the power of sensation. He termed the anterior root motor, and the posterior sensory. It has since been ascertained that the anterior roots carry outwards other impulses that do not result in motion, and that the posterior roots carry inwards impulses which may not result in sensation. Therefore, it is more correct to term these roots respectively *afferent* and *efferent*. If the anterior root be divided between the point of its origin from the cells of the anterior horn of the spinal cord and its junction with the posterior root, the part unconnected with the cord will waste along the whole length of the nerve, and the muscles which it supplies will waste also. The

cells in connection with the anterior roots, therefore, not only send out motor impulses, but exert a nutritive or *trophic* influence on the nerve and muscle. Division of the posterior root beyond its ganglion is followed by wasting of the corresponding fibres of the nerve to their ultimate termination. If the root be cut between the ganglion and the spinal cord, the part attached to

Fig. 7.

Fig. 8.

the ganglion remains unaltered, while that connected with the spinal cord wastes. This shows that the ganglion of the posterior root exerts a trophic influence on the fibres connected with it. If the nerve be divided after the junction of the two roots, the whole of the nerve farthest from the spinal cord will waste.

The afferent nerve impulses which pass along the posterior roots comprise those which give rise to the sense of touch, pain, and temperature, and to reflex movements of various kinds without necessarily exciting our consciousness, such as those concerned with the maintenance of the equilibrium

of the body, and with the functions of the internal organs.

Reflex Action.—The function of the nervous system is to bring any part of the organism into relation with any other part without the necessity of direct nervous connections from every part to every other part. It is like a telephone exchange where each subscriber has a central terminal which can be put into connection with that of any other subscriber. The nervous system, however, is more efficient, as the channels which bring in messages from different parts of the body (afferent fibres from sense organs) are different from the fibres (efferent) which convey messages outwards to organs which perform some action in response. The simplest mechanism consists of a sensory or receptive neurone and a motor neurone. This is a *reflex arc* in which a sensory impression gives rise to a motor response. It is the functional unit of the nervous system, as the neurone is the anatomical unit. As the organism increased in complexity, a third or association neurone arose which connected the neurones of one segment with those of another segment. The progress of the nervous centres in complexity and efficiency depends essentially on the formation of longer and longer association neurones which extend farther and farther from the original reflex arc, and thus the most highly developed part of the nervous system, the cerebral cortex, consists largely in man of association neurones.

A reflex arc usually consists of at least three neurones, a sensory, an association, and a motor (fig. 9). The simplest reflexes take place in the spinal cord, but the more highly complicated and specialised reflexes are carried out through the brain, which exerts a controlling influence upon all reflex response, inhibiting, exciting, changing excitation to inhibition, or *vice versa* as required, and thus constituting voluntary or volitional action. It is possible to explain the whole action of the nervous system as the result of the integration, co-ordination, interaction, combination, and adjustment of reflex activity.

The *sympathetic nervous system*, in contrast to the cerebro-spinal system which is under the control of the will, supplies those organs whose functions are not under voluntary control. It innervates the heart-muscle, the plain muscle in the walls of the blood-vessels, and in the walls of the other contractile viscera, such as the stomach, intestine, bladder, and reproductive organs, and supplies secretory fibres to the glands. It is not an independent nervous system, but an outflow from the cerebro-spinal, and is distinguished by its connections with neurones lying outside the latter, together with its formation of peripheral plexuses at the places of its distribution. It is entirely efferent. Its overflow from the central nervous system occurs at four regions, the mid-brain, the medulla oblongata, the dorsal and the sacral regions of the spinal cord. The cells of origin in the spinal cord are situated in the lateral horn of gray matter, and are known as the *intermedio-lateral*

Fig. 9.

A, sensory neurone; a, sensory spinal connection; b, sensory pathway to brain; B, association neurone; C, motor neurone; c, motor fibre from brain; M, muscle; S, sensory end-organ; A.C.C., anterior cornua cell (motor); P.G.C., posterior ganglion cell (sensory); S-A-b, sensory connection with brain; c-B-C, motor pathway from brain; S-A-a-B-c, reflex arc.

tract (see SPINAL CORD). The outflow is by the anterior roots.

Fig. 10.—The Sympathetic Nervous System; the right lateral walls of the chest and abdomen, and the stomach, intestines, liver, spleen, and pancreas being removed to bring it in view:

1, 2, 3, the superior, middle, and inferior cervical ganglia; 4, the two lines from this figure include the twelve dorsal

ganglia; 5, include the four lumbar ganglia; 6, include the five sacral ganglia; 7, the ganglion impar; 8, cardiac plexus; 9, solar plexus; 10, aortic plexus; 11, hypogastric plexus; a, the larynx; b, the trachea; c, arch of the aorta; c', external carotid; c'', internal carotid; d, the heart; e, e, the diaphragm; f, the cardiac end of the esophagus; g, thoracic and abdominal aorta; h, the kidney; i, the supra-renal capsule; k, the sacrum; l, the section of base of the skull; m, the bladder; n, the lower portion of the rectum.

The sympathetic nervous system consists of a series of ganglia situated on either side of the spinal column along its whole length. In the dorsal, lumbar, and sacral regions the ganglia correspond in number to the vertebræ; but in the cervical region there are only three, of such large size, however, that they are generally supposed to represent the fusion of a number of ganglia. Below, the two chains unite in front of the coccyx in a single ganglion. These ganglia are formed of multipolar nerve-cells (fig. 5, A), and are united with each other by gray nerve-fibres. Each ganglion gives to its corresponding spinal (or cranial) nerve a gray non-medullated nerve, and receives from it a fine white medullated nerve. The fibres of distribution may be studied in fig. 10. They pass to the blood-vessels and to the mucous membranes and muscular coats of the various internal viscera, and become united with each other in fine networks or plexuses, on many of which nerve-cells or ganglia are situated.

The sympathetic chain is continued upwards as a fine plexus of nerves on the internal carotid artery, on the various branches of which it is distributed. From the superior cervical ganglion also fibres pass to the various arteries in the neck and face, and to form, along with the pneumogastric and glosso-pharyngeal nerves, the pharyngeal plexus on the muscles and mucous membrane of the pharynx.

From some of the cervical and upper thoracic ganglia fibres pass into the chest, to form also, along with the pneumogastric nerve, two important plexuses, named pulmonary and cardiac, from which branches pass to the lungs and heart, and undoubtedly influence their functions. From the thoracic ganglia also arise the three splanchnic nerves which pass into the abdomen to enter the solar or epigastric and the renal plexus. The solar plexus is situated at the pit of the stomach, and is connected with two large semilunar ganglia, which send branches to all the blood-vessels and to all the organs within the abdomen. It is owing to the relations and functions of the solar plexus that blows in this region are so dangerous. The hypogastric plexus arises from the lumbar ganglia, and sends branches to the blood-vessels and to the organs in the lower part of the abdominal cavity, more especially the organs of generation, the lower bowel, and the bladder.

In the more primitive animals the sympathetic system is less conspicuous, its place being taken by masses of cells known as *chromaffine* cells. These cells contain adrenalin, and are found best developed in man in the medulla of the suprarenal glands. The tone of the vascular system depends on a continuous outflow of adrenalin into the blood, the sympathetic nerves alone being unable to maintain this tone in its absence.

The tissues and organs supplied by the sympathetic system all possess two sets of nerve fibres. These are opposite in function, one set being motor, the other inhibitory. The motor or accelerator fibres arise exclusively from the dorsal outflow from the spinal cord, while the inhibitory fibres arise from the remaining three regions. The latter have been termed 'parasympathetic' in contrast to the former, to which the term 'sympathetic' is becoming restricted. The heart, for instance, is supplied by an accelerator group of

fibres which quickens its action, and by an inhibitory group which slows it; the blood-vessels are supplied by vaso-constrictor and vaso-dilator fibres, &c. The characteristic quality of the innervation of all these tissues is due to the fact that their functions are able to continue independently of the nervous system, although influenced by it.

Although the sympathetic and parasympathetic systems act separately from each other, and may be influenced independently by physiological stimulation and by drugs, and although their actions are antagonistic, it is possible they may both be controlled from some common centre. A disturbance of their normal balance, however, may lead to the ascendancy of either system, and a condition of hypertonus, either vagal or sympathetic, may result with characteristic symptoms of illness.

See Quain's *Anatomy*, vol. iii.; Sherrington, *Integrative Action of Nervous System*; Gaskell, *Involuntary Nervous System*; Keith Lucas, *Conduction of Nervous Impulse*; Schäfer, *Text-book of Physiology*.

Nesle, TOUR DE. The ancient castle of the noble family of Nesle stood, with its gate and tower, at an angle of the city wall of Paris, on the south bank of the Seine, where now stands the palace of the Institute. It came into the hands of the crown, was the scene of events recorded by Brantôme, and was bought by Cardinal Mazarin as the site for his college.

Ness, LOCH, a long, narrow lake of Inverness-shire, the second largest in Scotland, $6\frac{1}{2}$ miles SW. of Inverness. Lying some 50 feet above sea-level, it extends $24\frac{1}{2}$ miles north-north-eastward, and has an average breadth of 1 mile, with an area of $21\frac{1}{2}$ sq. m. It receives the Morriston, Oich, Foyers (q.v.), and other streams, and sends off the river Ness to the Moray Firth. It lies in the valley of Glenmore, on the line of the Caledonian Canal (q.v.), and is enclosed by steep mountains—the highest, Mealfourvie (2284 feet). Owing to its great depth (maximum 754 feet) it never freezes to any considerable extent. See FORT AUGUSTUS.

Nesselrode, KARL ROBERT, COUNT, Russian diplomatist, was born on the 14th December 1780, at Lisbon, where his father, a descendant of an ancient noble family on the lower Rhine, was then Russian ambassador. He gained in a high degree the esteem and confidence of the Emperor Alexander, and in 1814 he accompanied the Russian emperor to France, where he took a principal part in all the negotiations which ended in the peace of Paris; and he was one of the most prominent of the plenipotentiaries in the Congress of Vienna, and one of the most active diplomatists of the Holy Alliance. The Emperor Nicholas reposed in him the same confidence, and amidst the European convulsions of 1848 and 1849 Russia, under his guidance, refrained from interference, till an opportunity occurred of dealing a deadly blow to the revolutionary cause in Hungary. Being one of the chiefs of the moderate party in Russia, Nesselrode exerted himself to preserve peace with the Western Powers; and after the war had broken out in 1854 he undoubtedly strove for the re-establishment of peace. After the accession of Alexander II. he retired from the direction of foreign affairs, and was succeeded by Prince Alexander Gortschakoff, but retained the dignity of chancellor of the empire. He died 23d March 1862, and his autobiography appeared at Berlin in 1866, his *Lettres et Papiers* in 1904–11.

Nessus. See HERCULES.

Nestor, according to ancient Greek legend, the son of Neleus and Chloris, born in the Messenian Pylos, escaped destruction when Hercules slew all his brothers. He married Eurydice, by whom he became the father of a numerous family. In his youth he was distinguished for valour in wars with

the Arcadians, Eleians, and the Centaurs, and in his advanced age for wisdom. Although he was an old man when the expedition against Troy was undertaken, he joined it with his Pylians in sixty ships. Homer makes him the great counsellor of the Greek chiefs, and extols his eloquence as superior even to that of Ulysses. Nestor returned in safety to his own dominions after the fall of Troy, and continued for long to rule over the people of Pylos.—For the birds called Nestor, see KEA.

Nestorius, a native of Germanicia, a city of northern Syria, in the patriarchate of Antioch, was probably a disciple of the celebrated Theodore of Mopsuestia. Having received priest's orders at Antioch, he became so eminent for his zeal, ascetic life, and eloquence in preaching that he was selected by the emperor as patriarch of Constantinople (April 428). Soon after his consecration a controversy arose as to the divine and human natures of our Lord, in which Nestorius took a leading part. The presbyter Anastasius, having in a sermon denied that the Virgin Mary could be truly called the Mother of God (*θεοτόκος*), it being not God the Logos but only the human nature which had a mother and suffered pain and death, Nestorius warmly defended Anastasius, and elaborated his view into the theory which has since been known by his name. He held that Mary was the Mother of Christ (*χριστοτόκος*), or the Receiver or Conceiver of God (*θεοδέχχος*), and that, while the divinity of the Logos is to be distinguished from the temple of his flesh, yet there remained but one person in the God-man. By his antagonists he was accused of exaggerating the distinction of two natures into a co-existence of two persons (*προσώπων ἑνους*)—the human person of Christ and the Divine Person of the Word. A vigorous controversy ensued, which extended from Constantinople to the other patriarchates, and drew from Cyril of Alexandria a formal condemnation of the doctrine of Nestorius in twelve anathemas, and a similar condemnation, accompanied by a threat of deposition and excommunication, from Celestine, Bishop of Rome, unless he would withdraw the obnoxious doctrine. Nestorius remaining firm in his opinions, a general council was convened at Ephesus in 431, at which Cyril took the most active and prominent part, and in which, notwithstanding the absence of John the Patriarch of Antioch and his bishops, Nestorius was condemned and deposed. Considerable opposition was offered to this judgment for a time, but ultimately the emperor was led to side with Cyril. Nestorius was confined in a monastery, and, after four years, banished to Petra in Arabia. He next found shelter in the Greater Oasis in Upper Egypt, and, after several changes of his place of confinement, died in exile, time and place alike unknown. His *Bazaar of Heracleides of Damascus* shows that he must have been alive just before the Council of Chalcedon (451), and that he was himself opposed to the so-called Nestorianism that the Council of Ephesus condemned.

See Bethune-Baker, *Nestorius and his Teaching* (1908); F. Loofs, *Nestoriana* (1905), and *Nestorius and his Position in the History of Christian Doctrine* (1914); and his own *Bazaar of Heracleides* (ed. Bedjan, 1910; trans. Driver and Hodgson, 1925).

The sect of the NESTORIANS, formed in the 5th century, was, after its exclusion from the Roman empire, extended into Persia, India, and even China. The teachers who were driven out of Edessa (489) settled at Nisibis, which soon became an active centre of learning and missionary enterprise throughout Persia. Babæus, Bishop of Seleucia (498–503), assumed the title of patriarch, and under his successors the sect grew rapidly and produced many learned theologians and philoso-

phers, and not a few very eminent physicians. Under the rule of the khalifs the Nestorians enjoyed toleration, and spread in Arabia, Syria, and Palestine, and even to Samarkand, Herat, and China. The Prester John (q.v.) of romance was a Christian of this colour, and there is a tradition that Mohammed learned what he knew of Christianity from Sergius, a Nestorian monk. In the middle of the 13th century as many as twenty-five metropolitans owned the jurisdiction of the Nestorian patriarch, but after the persecutions of Tamerlane they dwindled away. Meantime the Roman Catholic Church had been active in missionary labours amongst them. In the 16th century a great schism took place, a portion renouncing their distinctive doctrine, and placing themselves under the jurisdiction of the Roman pontiff, to whom, under the title of Chaldean Christians, they have since remained faithful. Their patriarchs still bear the traditional name of Joseph. The others to the present day maintain their old creed and their ancient organisation. Their chief seat is Kotchanes, near Djulamerk, in the mountain-ranges of Kurdistan. They are at present a poor and illiterate race. Their patriarch since the close of the 17th century has borne the name of Simeon. The bishops are bound to observe celibacy, but marriage is permitted to the priests and inferior clergy. Their liturgical books recognise seven sacraments, but confession is infrequent, if not altogether disused. Marriage is dissoluble by the sentence of the patriarch; communion is administered in both kinds; and although the language of the liturgy plainly implies the belief in transubstantiation, yet that doctrine is not popularly held among them. The fasts are strict, and of very long duration, amounting to very nearly one-half of the entire year. They pray for the dead, but are said to reject the notion of purgatory, and the only sacred symbol which they use or reverence is the cross. The Nestorians of Kurdistan, like the Christians of the Lebanon, have suffered much from time to time through the fanaticism of the wild tribes among whom they reside. There has been among them since 1834 an active American mission, which has translated the Bible into their speech—a dialect of the old Aramaic.

There is another body of Nestorians who have existed in south India from the period of the early migrations of the sect, known as Syrian Christians or Christians of St Thomas (see THOMAS, CHRISTIANS OF ST), and works there noted.

See GREEK CHURCH; Maclean, *The Catholicos of the East and his People* (1892); Parry, *Six Months in a Syrian Monastery* (1895); Hefele's *Councils*; Perkins's *Residence of Eight Years in Persia among the Nestorian Christians* (Andover, 1843); Badger's *Nestorians and their Rituals* (1852); Anderson's *Oriental Churches* (1872); Dean Stanley's *History of the Eastern Church*; Wigram, *The Assyrian Church* (1910); Heazell and Margoliouth, *Kurds and Christians* (1913); and books on the Nestorian monument at Si-ngan-fu in China by Legge (1888), Havret (*Variétés Sinologiques*, 1898), Carus (1909), and Saeki (1916).

Nests, structures prepared for egg-laying, brooding, and nursing. The word is also applied to a shelter for the adult animals, apart from eggs or young. Nest-making reaches its finest expression in birds, but many other kinds of animals make nests—e.g. squirrels and harvest-mice, sticklebacks in the shore-pool and Antennarius among the Sargasso Weed, some spiders, and many insects like bees and wasps. See ANT, BEE, BIRD, &c.; Alfred Russel Wallace in *Contributions to the Theory of Natural Selection*; C. Lloyd Morgan's *Habit and Instinct* (1897); W. P. Pycraft's *History of Birds* (1910); J. Arthur Thomson's *Biology of the Seasons* (1911).

EDIBLE BIRDS' NEST, a nest chiefly composed by the consolidated whitish isinglass-like mucous secretion formed by the salivary glands of diminutive swifts belonging to the genus *Collocalia*. About a dozen species are known in the Indian and Australian regions; they nest in caves which are also tenanted by bats, and they fasten their saucer-shaped nests to the walls. In some species there may be an admixture of seaweed, lichen, moss, feathers, &c., along with the salivary secretion; or this may be the case when the bird makes a second nest after the first has been removed. The nests of the Esculent Swiftlet (*C. fuciphaga*) are particularly pure, and over 3½ millions have been known to be exported from Borneo alone.

The Edible Nest of the Swiftlet of South Java.

in one year. They are used in various Chinese 'birds' nest soups,' and are often said to be worth their weight in silver. The import to Canton has sometimes amounted to 25 million nests in a year. The birds are occasionally called Salangane, from one of the islands which they frequent. The nests have been analysed by Dr J. R. Green, who found that the chief constituent was allied to mucin. A similar material is secreted by many animals, and many swifts use it in glueing the materials of their nests. What is peculiar in *Collocalia* is that the secretion of the salivary glands is very copious. The persistent belief that the mucilage of the nest is partly extrinsic, and derived from seaweed, fish-spawn, and the like, seems unwarranted. See articles by Green, Layard, and Pryer in *Nature*, vols. xxx.-xxxiv.; Green in *Journal of Physiology*, vi. pp. 40-45; Pryer in *Proc. Zoological Soc.*, 1885, pp. 532-58; Annandale in *Chambers's Journal* (1901); McGregor, *Philippine Birds* (1909); and Newton's *Dictionary of Birds* (1896), p. 936.

Netherlands, the north-west corner of the great north European plain, a triangular region between France, Germany, and the sea, lying mainly in the basins of the Scheldt, the Meuse, and the lower Rhine, is now divided into nearly equal parts between the kingdoms of Holland and Belgium. The official designation of Netherlands is retained by what we commonly call Holland (q.v.), and under that head the early history common to the two is discussed; while the history of the 'Spanish Netherlands' falls mainly under the head of Flanders (q.v.) and Belgium (q.v.). The history of the Dutch and Flemish language and literature will be found under HOLLAND.

Netherlands Company. See JAVA.

Nethersole, ORGA, an actress born in London in 1870, who made her début at Brighton in 1887, and from 1889 played at the Garrick under John Hare. She became lessee and manager of the Court Theatre in 1894, subsequently managed the

Adelphi and Her Majesty's, and made tours in Australia and the United States, and played in Paris.

Néthou. See PYRENEES.

Netley, a place on the east side of Southampton Water, 3 miles SE. of Southampton, with a ruined Cistercian abbey, founded in the time of Henry III., and the Royal Victoria Hospital. The latter superb building (begun 1856) is for the reception of invalids from the army on foreign service, and from the troops serving in the adjoining military districts. The Army Medical School formerly attached has been superseded by the Royal Army Medical College in London.

Nets. A net is a kind of trap formed of string worked into open meshes and used for capturing fishes, birds, and other animals, and for other purposes. The string is knotted at the intersections so as to keep the meshes of their original size.

Remains of nets belonging to the stone age have been found at Robenhauseu and Vinelz in Switzerland. Not only do the paintings on ancient Egyptian monuments show that in the days when these were executed nets were in common use, but portions of actual nets of great age have been obtained in Egypt. They are also represented on the monuments of ancient Greece. The Eskimo and Tchukchis make nets of twisted sinew or of strips of seal-skin, and the Chinese construct fine nets from the cocoons of the wild silkworm, which are soaked in oil so as to render them barely visible. Silk nets also are used in Greece. In some parts of the world nets are made of the fibres of plants but little known; but in civilised countries the chief materials used in their construction are hemp and cotton, and to a less extent flax. More nets are now made of cotton than of hemp, because, although the former are less durable, they are of lighter weight, more easily managed, and a smaller number of corks and bungs suffices to float them.

The making of nets by hand is an extremely simple operation. Only two instruments are required—viz. a netting-needle like *a* in the figure, for meshes above one-half inch in width, or one like

b for meshes under this size, and a mesh-pin, which is simply a straight piece of wood of oval section and a few inches long, upon which the loops are formed. If the meshes are to be one inch from knot to knot, then the circumference of the mesh-pin requires to be two inches. There are two ways of forming the knots on hand-made nets (see KNOTS, figs. 11 and 13), but both are equally simple, and the whole process can be learned in a few minutes by seeing an operator at work. In some countries nets are still largely made by hand.

Netting-machines are now extensively used. The looms are of complicated construction, and it would require a considerable number of illustrations and detailed descriptions to give even a general idea of how they perform their work. One of the most successful of these is known as the Paterson net-loom. It was invented by James Paterson, brought into a more practical shape (1835) by Walter Ritchie, both of Mussel-

burgh, and since improved by Messrs J. & W. Stuart. (The knot made by this loom is the same as fig. 13 of KNOTS.) It works by a peculiar arrangement of hooks, needles, and sinkers. An improved form of a net-loom, on a different principle, invented by a Frenchman named Pecqueur, in 1840, was improved by MM. Baudouin and Jouannin.

A variety of nets are used by fishermen, but the principal kinds are the *seine*, the *drift-net*, the *moored-net*, and the *trawl* (see FISHERIES). The net used for taking the tunny in the Mediterranean is often nearly a mile long, and some Russian hand-made nets are 3000 feet in length. Means are adopted to increase the durability of cotton and hemp nets, especially of the former. One plan is to tar them; but, although this to some extent prevents the injurious action of sea-water upon them, it has the disadvantage of hiding faulty parts. They are, however, much more frequently 'barked' in an infusion of cutch (see CATECHU), which like tar lessens the action of salt water upon them and at the same time admits of the state of the meshes being better seen. A solution of alum is also useful in preserving the fibre of the string of which nets are made.

One or two kinds of nets are made for catching birds, such as *fly-nets* for waders frequenting the seashore, and *clap-nets* for small birds (see WILD-FOWL). Fine nets are used to capture insects, and by the inhabitants of some countries as a protection from mosquitoes.

Nettle (*Urtica*), a genus of plants of the natural order Urticaceæ, having unisexual flowers, the male and female on the same or separate plants; the male flowers with a 4-parted perianth and four stamens; the female flowers with a 2-parted perianth and a tufted stigma; the fruit an achenium. The species are herbaceous plants, shrubs, or even trees, many of them covered with stinging Hairs (q.v.), which pierce the skin when touched, and emit an acrid juice, often causing much inflammation and pain. When a nettle is grasped in such a way as to press the hairs to the stem no stinging ensues; but the slightest inadvertent touch of some of the species produces very severe pain. The acidity which is characteristic of all nettles, more or less, is by some said to be due to bicarbonate of ammonia, or according to others free formic acid being present in the limpid juice secreted by the glandular hairs of the leaves and stems. The stinging of the native nettles of Europe is trifling in comparison with that of *U. spatulata*, the *Devil's Leaf* of Timor. Of British species the most venomous, but the most rare, is the Roman Nettle (*U. pilulifera*); next to it is the Small Nettle (*U. urens*), frequent about towns and villages, and in waste and cultivated ground; whilst the least venomous is the most common and only perennial species, the Great Nettle (*U. dioica*), everywhere abundant, but particularly near human habitations, or their former sites, the desolation of which it may be said to proclaim. The roots of nettles, boiled with alum, afford a yellow dye; and the juice of the stalks and leaves has been used to dye woollen stuffs of a beautiful and permanent green. The young shoots of *U. dioica* have been much used in some parts of Scotland and other countries as greens, and their peculiar flavour is much relished by some, although, in general, the use of them is confined to the poor. They are valuable as antiscorbutics, but are gritty to the taste from the quantity of crystals (Cystoliths) contained. The stinging power of nettles is dissipated by boiling and drying. Their high value as food for swine and poultry, especially turkeys, is well known in many countries. The seeds

are extremely nutritious to poultry, and are given to horses by jockeys, in order to make them lively when they are to be offered for sale. The stalks and leaves of nettles are employed in some parts of England for the manufacture of a light kind of beer, called *Nettle Beer*. The bast-fibre of nettles is useful for textile purposes. Yarn and cloth, both of the coarsest and finest descriptions, can be made of it. The fibre of *U. dioica* was used by the ancient Egyptians, and is still used in Piedmont and elsewhere, as it has been in Germany since the Great War. It makes excellent gasmantles. When wanted for fibre the plant is cut in the middle of summer, and treated like hemp. The fibre of *U. cannabina*, a native of the south of Siberia, central Asia, is much used. The seeds and herbage of *U. membranacea* are used in Egypt as emmenagogue and aphrodisiac; and somewhat similar properties are ascribed to *U. dioica*.—The Dead-nettle (q.v.) is quite a distinct plant; so is the Nettle-tree (q.v.).

Nettle-cloth. See *BOEHMERIA*.

Nettlerash, or *URTICARIA* (Lat. *urtica*, 'nettle'), is the term applied to a common form of eruption on the skin. The eruption consists of wheals, or little solid eminences of irregular outline, and either white or red, or most commonly both red and white, there being a white centre with a red margin. The rash is accompanied with great heat, itching, and irritation, but is always aggravated by scratching; the appearance on the skin and the sensation being very much like the appearance and feeling produced by the stinging of nettles; and hence the origin of its names. The eruption is characterised by the extreme rapidity with which it appears and disappears; the whole duration of the attack may be a few hours or even less; but it is extremely apt to recur at regular or irregular intervals: it is very rare for the wheals to persist more than a day.

The disease may be either acute or chronic. In the acute form feverishness may precede the rash by a few hours, or may be altogether absent. The disorder is often connected with some derangement of the digestive organs, and may be traced to the imperfect digestion of special articles of food, such as oatmeal, the kernels of fruit, strawberries, cucumbers, mushrooms, and especially oysters, mussels, and crabs, which are eaten with perfect impunity by most persons. It may be brought on also by local causes of irritation, and frequently complicates other irritable diseases of the skin.

The chronic form is often very troublesome, and frequently comes on periodically in the evening. Cases are reported in which persons have been afflicted for ten years continuously by this form of the disease. It is characterised by constant recurrence during long periods, not by persistence of a single outbreak of the eruption. In the treatment of the acute form local causes of irritation must first be looked for and removed. Where it is brought on by some article of diet relief is often obtained by taking ten grains of bicarbonate of soda (baking-soda); but it may be necessary to administer emetics and purgatives, if vomiting and diarrhoea do not occur spontaneously. In the chronic form the patient should, in the first place, determine whether the rash is caused by any particular article of diet, and if this seems not to be the case an attempt must be made to improve the state of the digestive organs. A few grains of rhubarb taken daily, just before breakfast and before dinner, will sometimes effect a cure. Numerous other remedies have been recommended; perhaps the most generally useful is a powder containing rhubarb two grains, bismuth

carbonate twenty grains, and bicarbonate of soda ten grains. Although external applications are usually of little avail, dusting the itching surface with boric and talc powder sometimes affords temporary relief; and a still more useful application is a lotion composed of a drachm of the carbonate of ammonia, a drachm of the acetate of lead, half an ounce of laudanum, and eight ounces of rose-water.

Nettle-tree (*Celtis*), a genus of deciduous trees of the natural order *Ulmaceæ*, with simple and generally serrated leaves, considerably resembling those of the Common Nettle, but not stinging. The genus is distinguished chiefly by its fruit, which is a fleshy, globose, or sub-globose 1-celled drupe. The Common or European Nettle-tree (*C. australis*) is a native of the south of Europe, the west of Asia, and the north of Africa. It grows to a height of 30 to 40 feet, and is a very handsome tree, often planted along public walks in the south of France and north of Italy. The wood is very compact, very durable, and takes a high polish. It was formerly much imported into Britain for the use of coachmakers, and is used in Italy by musical-instrument makers for flutes and pipes. The flowers are inconspicuous, axillary, and solitary; the fruit black, resembling a small wild cherry, not eatable till after the first frosts, and then very sweet. The kernel yields a useful fixed oil. The tree succeeds well in the south of England. *C. occidentalis* is a native of North America from Canada to Texas, and is also called Hackberry. Its leaves are much broader than those of *C. australis*, its fruit very similar. It is a much larger tree, attaining a height of 60 to 80 feet. The Sugar-berry is *C. mississippiensis*. See also *LAPORTEA*.

Neu-Brandenburg, a town of Mecklenburg-Strelitz, is situated on Tollense See, 20 miles NNE. of Neu-Strelitz by rail; pop. 13,000.

Neuchâtel, or *NEUFCHÂTEL* (Ger. *Neuenburg*), a canton in the west of Switzerland, between the Lake of Neuchâtel and the French frontier. Neuchâtel lies in the midst of the Jura Mountains, four chains of which, running from north-east to south-west, traverse the canton, and are separated by elevated longitudinal valleys. The greater number of the numerous streams which water the canton flow into the Rhine; several are feeders of the Lake of Neuchâtel, which, lying 1420 feet above sea-level, and 472 feet deep, is 25 miles long by from 3 to 6 wide. The Thiele serves as its outlet, and carries its waters into the neighbouring lake of Bienne, and thence into the river Aar. Pop. of the canton (1870) 97,284; (1920) 131,349, of whom three-fourths speak French, and four-fifths are Protestants. Asphalt is exported; good wine, chocolate, electrical apparatus, and lace are made; but the speciality of the canton is watch-making. The history of Neuchâtel was identical with that of Burgundy till the 11th century; and after the principality had been for a time incorporated with the territories of the Counts of Chalon, to whom it had been granted in 1288 by Rudolph of Hapsburg, it passed to the House of Longueville. In 1707, on the extinction of the Neuchâtel branch of the latter family, some fifteen claimants came forward to advance more or less valid pretensions to the Neuchâtel territory. Frederick I. of Prussia, who based his claim to the principality of Neuchâtel on the ground of his descent from the first Prince of Orange, a descendant of the House of Chalon, was the successful candidate; and from his time it continued associated with Prussia, till 1806, when Napoleon bestowed it upon General Berthier; but in 1814 it was restored to the House of Brandenburg. A republican constitution was adopted in

1848, in spite of Prussian protest; and there was civil war in 1856. The connection with Prussia was wholly dissolved in 1857, and Neuchâtel is now a member of the Swiss Confederation.

NEUCHÂTEL, chief town of the canton, occupies a magnificent site on the north-west shore of the Lake of Neuchâtel, 85 miles by rail NNE. of Geneva. It is noted for its many charitable, educational, and artistic institutions, and has a château (restored 1866), a university (1909), a statue of Farel (1875), &c. There are manufactures of watches, jewellery, &c. Pop. 23,000.—The famous Neuchâtel cream-cheeses are made, not here, but at Neuchâtel-en-Bray, a small Norman town, 25 miles SE. of Dieppe by rail.

Neuhoff. See THEODORE (of Corsica).

Neuilly, or NEUILLY-SUR-SEINE, immediately north of the Bois de Boulogne, is practically a suburb of Paris. Near the Seine stood the Château de Neuilly, built by Louis XV., but burnt at the revolution in 1848. Peace with Bulgaria was signed in the Town Hall, 27th November 1919. Pop. 50,000.

Neumes. See MUSIC.

Neumünster, a prosperous manufacturing town of Holstein, 20 miles by rail S. by W. of Kiel. Its tanning industry is very important. Pop. 36,000.

Neunkirchen, a town of Rhenish Prussia (Saar basin), 38 miles SE. of Trier, has important coal-mines and iron-works; pop. 38,500.

Neunkirchen, a town of Lower Austria, 38 miles SSW. of Vienna, in a mining district, with iron-foundry and other industries; pop. 11,000.

Neu-Pommern. See NEW BRITAIN.

Neuralgia (Gr. *neuron*, 'nerve'; *algos*, 'pain') is a term employed to designate pain of a purely nervous character, usually unaccompanied by inflammation, fever, or any appreciable change of structure in the affected part. The pain, which occurs in paroxysms, usually followed by complete remissions, is of every possible degree and character, being described in different cases as piercing, tearing, burning, &c. These paroxysms may occur at intervals of a few seconds only, or they may take place daily or on alternate days, or they may be separated by much longer intervals, which are often, but by no means always, of a regular length. The pain is usually felt not only at the place where the nerves terminate, but along their course. It is usually confined to one side of the body, and is very rarely, if ever, quite symmetrical. In prolonged cases 'tender points' are developed along the course of the affected nerves. After the pain has subsided the painful parts are usually tender to the touch. Very frequently the sensibility of the skin supplied by the affected nerve is somewhat diminished. With the pain there is frequently spasmodic twitching of the adjacent muscles. The duration of the disease is very uncertain. The patient may have only a single attack, or he may be liable to recurring attacks for months, years, or even for his whole life; it is, however, very seldom that the disease occurs but once. Death scarcely ever results directly from this affection, but the pain may, by its severity and persistence, gradually undermine the constitution.

The disease may attack any part of the body where there are nerves; but in no part does it occur so frequently as in the face, its seat being in the facial branches of the fifth pair of nerves (the trifacial nerves; see NERVOUS SYSTEM). The most severe form of facial neuralgia, happily rare, is known as *tic douloureux*. 'The absolute suddenness with which the pain comes on is one of its most remarkable characters. The patient is per-

haps sitting quietly reading, when he jumps up from his seat, and rushes up and down the room with his hand forcibly pressed against his cheek. Or he may rock himself backwards and forwards in his chair, crying out or uttering deep groans. In ten or twenty seconds, or a minute at the longest, the paroxysm is over. It ceases as abruptly as it began.' 'The paroxysms may return every few minutes.' 'Sometimes remissions occur, the patient remaining free from the disease for several days together, or even for months. But presently it returns, and is as severe as ever.' 'A patient who suffers under *tic douloureux* acquires an expression of intense distress and suffering; his countenance is worn and wrinkled, and looks like that of a much older person' (Fagge, *Practice of Medicine*).

'The paroxysms of suffering in this frightful disease are apt to be brought on by apparently trivial causes—by a slight touch, by a current of air blowing upon the face, by a sudden jar or shake of the bed on which the patient is lying, by a knock at the door, or even by directing the patient's attention to his malady, by speaking of it or asking him questions about it. The necessary movements of the face in speaking or eating are often sufficient to provoke or renew the paroxysm. At the same time, firm pressure made upon the painful part frequently gives relief, and causes a sense of numbness to take the place of the previous agony' (Sir J. Watson).

Facial neuralgia of a less severe type than *tic douloureux* is very much more common, in fact it is by far the most frequent form of the disease; the reason probably being that the trifacial nerve, lying superficially, and being distributed over a part of the surface which is usually unprotected by any artificial covering, is very liable, for that reason, to be affected by exposure to atmospheric influences, which are undoubtedly to be included among the exciting causes of this disease. Amongst other seats of neuralgia may be mentioned the arm, especially the forearm, the spaces between the ribs, especially between the sixth and ninth, and the lower extremity, where it most frequently affects the sciatic nerve, giving rise to the affection known as *Sciatica*, which, however, not always being pure neuralgia, will be noticed in a separate article. The internal organs may also be the seat of neuralgia—e.g. the heart (some cases of *Angina Pectoris*, q.v.), stomach, or kidney.

The causes of neuralgia are various. Excluding inflammation of the nervous trunk or *neuritis*, the pain may be excited by a tumour pressing on the nerve or originating in its substance, or by roughness of a bony surface with which the nerve may be in contact, as when it passes through a foramen. Sometimes, again, irritation applied to one branch of a nerve will give rise to pain at the extremity of another branch of the same nerve, the sensation being reflected along the branch which is not directly exposed to the irritation. Thus, facial neuralgia very frequently depends upon diseased conditions of the teeth, even if they themselves are not painful. In this way we may explain the pain in the shoulder which often accompanies disease of the liver; the pain in the thigh, which is often associated with irritation of the kidney; the pain in the left arm, which is often coincident with disease of the heart, &c. Persons suffering from debility, *anæmia*, and a gouty or rheumatic constitution are so especially liable to neuralgia that these conditions, as also the presence of chronic malaria, must be placed among the predisposing causes. Amongst the exciting causes exposure to cold and wet, or to a cold dry east wind, is the most frequent; but fatigue, strong mental emotions, the abuse of tea, coffee, tobacco, and alcoholic drinks, a wound or bruise, the retrocession of gout,

rheumatism, or cutaneous eruptions, &c., occasionally suffice to excite the disease. The condition is often due to the effects of lead-poisoning, or of prolonged alcoholic indulgence, or it may follow some infectious disease like typhoid fever, diphtheria, &c.

Treatment.—In the first place, a careful search must be made for any possible local source of irritation; and next, hygienic conditions must be very carefully attended to; fresh air, regular bodily exercise, freedom from worry and overstrain of mind, plenty of sleep, an abundant supply of wholesome nourishment, are each essential. Fatty food, as cod-liver oil, butter, cream, is of especial importance.

Of drugs which give immediate relief to the pain, morphia, especially when administered hypodermically (q.v.), holds the first place. But it must be used with great caution, and not entrusted to the patient himself, lest a 'morphia habit' become established. Antipyrin, phenacetin, exalgin, and aspirin sometimes take the place of morphia, and are free from some of its disadvantages. Butyl-chloral and gelsemium are often useful in facial neuralgia. Bromides may give sufficient relief in milder cases. Relief from the suffering is often the first step towards recovery.

But in most cases some treatment is necessary to remove the constitutional state on which the neuralgia depends. Iron, quinine (especially when the pain recurs at regular intervals), arsenic, phosphorus, chloride of ammonium, are the medicines most generally useful. But the treatment must of course be adapted to the disorders, frequently digestive, present in each particular case.

Local applications can be of no permanent service in cases where the pain results from organic change, or from general constitutional causes; they will, however, often give considerable temporary relief. Amongst the most important local applications may be mentioned laudanum, tincture of aconite or aconitina ointment, belladonna-plaster, and chloroform (which should be applied upon a piece of linen saturated with it, and covered with oiled silk to prevent evaporation), mustard leaves or poultices, and small fly-blisters. The injection of cocaine or alcohol directly into the affected nerve sometimes effects a cure. Galvanism is also valuable.

Lastly, neuralgia, being a purely nervous affection, is often influenced by means calculated to make a strong impression on the mind of the patient; and hence it is that hypnotism and other applications which act more upon the mind than upon the body occasionally effect a cure.

In cases which have resisted all other modes of treatment surgical measures are sometimes necessary—viz. acupuncture, nerve-stretching (see under SCIATICA), or, in the last resort, removal of a portion of the affected nerve.

Neuritis, a term applied to inflammation of the nerves. The symptoms are those of neuralgia, with impairment of sensation, or localised paralysis, according as sensory or motor nerves are affected.

Neurone. See NERVOUS SYSTEM.

Neuroptera. See INSECTS.

Neu Sandec. See SANDEC (NEU).

Neusatz (Serb. *Novi Sad*; Magyar, *Ujvidék*), a town of Yugoslavia, on the left bank of the Danube, opposite Peterwardein (q.v.); pop. 40,000.

Neusiedler See (Magyar, *Fertő Tava*), a small lake on the frontier of Austria and Hungary, 22 miles SE. of Vienna. It is shallow (13 feet), and has lost much of its former area (133 sq. m.) by the draining of the adjoining marshes. From 1865 to 1870 it was dry. A canal carries flood water to the Rubnitz River.

Neuss, a town of Rhenish Prussia, near the Rhine, 4 miles W. of Düsseldorf. Its church of St Quirinus, a notable specimen of the transition from the round to the pointed style, was founded in 1209. Its west tower was accidentally burned down in 1914. Neuss has flourishing ironworks, foundries, flour mills, and manufactures of cottons, woollens, leather, paper, chicory, &c. In 1875-1919 the population grew from 15,600 to 40,000.

Neustadt, a town of Upper Silesia, 25 miles SW. of Oppeln. It is the seat of considerable industry, woollen and linen fabrics and carpets being the staple manufactures. Pop. 20,000.

Neustadt, or WIENER-NEUSTADT, one of the most beautiful towns of Lower Austria, is situated 32 miles S. of Vienna by rail. The town is overlooked by a large old castle, whose fine Gothic chapel (1460), rich in painted windows, is the burial-place of the Emperor Maximilian I. The old church dates from 1230, and was restored in 1890; a Cistercian abbey (1444) and a town-house are notable buildings. Locomotives and machinery, wire, bells, pottery, starch, leather, and ribbons are amongst the manufactures. The city, called the 'Ever-faithful,' was founded in 1192, and was rebuilt after a great fire in 1834. Pop. 37,000.

Neustadt-an-der-Hardt, a town of Rhenish Bavaria, at the foot of the Hardt Mountains, 20 miles W. of Speyer. Its church, with several curious monuments, dates from the 14th century. It manufactures paper, cloth, soap, wine, brandy, &c. Pop. 20,000.

Neustrelitz, capital of Mecklenburg-Strelitz, pleasantly situated in a hilly district, between two lakes, 62 miles NNW. of Berlin. Founded in 1733, it is built in the form of an eight-rayed star, and contains the palace, with magnificent gardens. Pop. 11,500.

Neustria, the name given in the times of the Merovingians and Carolingians to the western portion of the Frank empire, after the quadruple division of it which took place in 511. Neustria contained three of these divisions. It extended originally from the mouth of the Scheldt to the Loire, and was bounded by Aquitania on the S., and by Burgundy and Austrasia (*Francia Orientalis*) on the E. The principal cities were Soissons, Paris, Orleans, and Tours. See the historical maps at EUROPE.

Neutral Salts. See SALTS.

Neutrality. Neutrals are states which in time of war take no part in the contest, but continue pacific intercourse with both belligerents. The aim of the doctrine of neutrality is to reconcile the right of belligerents to carry on their warlike operations with the no less undeniable right of other nations to pursue peacefully their ordinary business. For many years after the rise of modern international law the conduct of warfare was discussed only with reference to belligerents, and no intermediate relation between an ally and an enemy was recognised. Not, indeed, till the middle of the 18th century did the terms 'neutral' and 'neutrality' come into general use; for not till then was a systematic effort made to regulate the relations of belligerents to nations standing aloof from the war, or to define their reciprocal rights and duties.

As between belligerent states and neutral states, the principles whence spring the complicated rules of modern neutrality are in themselves extremely simple. On the one hand, the neutral, being neither judge nor party, must show absolute impartiality in his dealings with both belligerents; on the other hand, the belligerent must pay scrupulous respect to the sovereignty of his neutral neighbours. Accordingly, throughout a

war, neutrals continue diplomatic intercourse with both belligerents. The Hague Conference of 1907 expressly provided in the fifth convention, dealing with land warfare, that the territory of neutral powers is inviolable, and in the thirteenth convention, dealing with maritime warfare, that any act of hostility, including capture and the right of search committed by belligerent warships in the territorial waters of a neutral power, constitutes a violation of neutrality, and is strictly forbidden. Further, it is not permissible for a belligerent to organise or fit out combatant forces within neutral territory, or to use neutral land or waters as a base of operations against the enemy. On the other hand, a neutral state is not permitted to give armed assistance or to supply munitions of war to either belligerent; nor to lend money to either side or guarantee such loan. Under the fifth Hague Convention of 1907, a neutral power is expressly prohibited from allowing the passage of the land forces of a belligerent across any portion of its soil; but the neutrality of a power is not affected by the mere passage through its territorial waters of warships or prizes belonging to belligerents. Moreover, a neutral state is entitled to permit the passage over its territory of sick and wounded belonging to the belligerent armies. When bodies of belligerent troops are driven by the enemy across neutral borders, the practice is for the neutral state to disarm them as soon as they cross the frontier, and to intern them in the neutral territory until the conclusion of the war. During the Great War aircraft and their crews landing on neutral territory were as a rule interned. Prisoners of war who escape to neutral territory are set at liberty. A neutral power is bound to prevent the setting up of a belligerent prize-court in its territory or the use of any part of its territory as an information station by a belligerent. A neutral state is entitled to exclude impartially belligerent warships from entering its ports, subject only to the exception that such ships, if driven by stress of weather or reduced to an unseaworthy condition, have a right to shelter. It is usual, however, for neutral powers, instead of exercising the right of exclusion, to permit the entry into their ports of belligerent warships of both sides. When such permission is granted it is incumbent on the neutral power, in fulfilment of its obligation to refrain from aiding or increasing the fighting strength of either belligerent, to regulate the length of stay allowed to belligerent warships and their prizes in its ports, and the amount and nature of the supplies or equipment that may be taken in and of the repairs that may be executed. In the case of the *Appam*, a British vessel captured by the Germans in 1916, and taken into a port of the United States with a prize crew on board, it was held by the Supreme Court of the United States that the vessel, not having been brought into the neutral port on account of unseaworthiness, stress of weather, or want of fuel or provisions, must be released to the British owners. Regulations made by a neutral state for the protection of its neutrality must be scrupulously observed by the belligerents; and, on the other hand, a belligerent injured by the failure of a neutral to fulfil the obligations laid on it is entitled to demand reparation.

The property of private citizens of neutral states, if situated in belligerent territory, may sustain incidental damage during legitimate warlike operations; and such damage does not entitle the neutral owner to compensation. Under the Right of Angary (Low Latin *angaria*, 'forced service,') the property of neutral subjects within the limits of belligerent authority may be requisitioned or utilised by the belligerent to the extent required by urgent

military needs, subject to the payment of compensation. Thus, in 1918 Great Britain, in pursuance of the right of angary, requisitioned neutral Dutch ships temporarily within its control, making full compensation. In the same year this course was also adopted in the case of Dutch ships by the United States, France, and Italy. The contention of the Dutch government that the right of angary was in disuse was unavailing. At sea the commercial interests of belligerent and neutral merchants are so interwoven that it is difficult to separate them and strike at an enemy without injuring a friend; hence ever and again have arisen bitter controversies regarding the extent of a belligerent's power over the property of neutral citizens at sea. Two distinct principles for regulating the maritime capture of neutral property have at different times prevailed. By the one principle, the nationality of the ship determined liability to capture, so that neutral goods on hostile ships were liable to confiscation, while hostile goods on neutral ships went free. By the other principle, the nationality of the property determined its liability, so that neutral goods went free even though found on hostile ships, and hostile goods were liable to seizure even though found on neutral ships. In 1856 the Declaration of Paris provided (Art. 2) that the neutral flag should cover an enemy's goods, except contraband of war; and (Art. 3) that neutral goods, except contraband of war, should not be liable to capture even under the enemy's flag. The law, as thus laid down, is the old rule, 'Free ship, free goods,' without the corollary, 'Hostile ship, hostile goods.' Attempts had frequently been made at an earlier period, particularly by Prussia in the Silesian Loan controversy and by the Armed Neutralities of 1780 and 1800, to incorporate this principle into international law. The rules of the Declaration of Paris, which had been regarded as an acknowledged part of the law of nations, were, however, treated with scant respect during the war of 1914-18. The methods of naval warfare adopted by Germany and Austria—their ruthless submarine policy, their indiscriminate use of mines, and their declaration of 'prohibited zones,' affecting neutral vessels and extending over wide areas of the open sea—rendered it necessary for Great Britain and France, as a measure of reprisal, to treat the second and third articles of the Declaration of Paris as no longer binding on them. Experience in the Great War having revealed the inadequacy of the existing rules for the protection of neutral commerce, it is generally recognised that there is an urgent need for the formulation of new rules or a modification of the old rules, to meet the changed conditions of naval warfare. The treaty between the British Empire, the United States, France, Italy, and Japan, signed at Washington on 6th February 1922, contains important provisions, accepted as binding as between the signatory powers, dealing with the use of submarines as commerce-destroyers, and designed to secure more adequate protection for the lives and property of neutrals at sea.

Belligerents have the right of intercepting, even on board neutral vessels, such articles as are deemed contraband of war. In the war of 1914-18 the list of articles falling within this description was enormously extended (see CONTRABAND). Another instance in which a belligerent is entitled to interfere with the ships and property of neutral citizens is furnished by the law of blockade (see BLOCKADE). Neutral merchantmen sailing under belligerent convoy render themselves liable to capture by the warships of the other belligerent. Again, if during a war ships belonging to neutral citizens perform certain kinds of services on behalf of one of the belligerents, the other belligerent is entitled to

confiscate these ships. Among such un-neutral services against which a belligerent is entitled to protect itself, are reckoned voyages specially undertaken with a view to the transport of passengers who are embodied in the armed forces of the enemy, or with a view to the transmission of intelligence in the interest of the enemy; voyages undertaken under the orders or control of an agent placed on board by the enemy government; and, generally speaking, any act done by a neutral vessel which puts her in the position of taking a direct part in hostilities. The repression of contraband, the enforcement of blockade, and the exaction of penalties for un-neutral service lie, by international law, with the belligerent alone, and not with the neutral. The aggrieved belligerent does not complain to the neutral state, but strikes at the neutral citizen directly by capturing his property and condemning it in his own prize court.

Many questions arise with respect to the extent of the obligations, imposed on a neutral state, of restraining the conduct of its own citizens, and of enforcing the due observance of neutrality on all persons within its jurisdiction. Citizens of a neutral state may legitimately do many things which the government of the state is not permitted to do. Thus a neutral state is under no obligation to prevent its subjects from lending money to, or taking stocks in loans issued by, belligerents. So, too, a neutral state is not bound to forbid the export or transit by its subjects of munitions of war, or other articles, for the use of one or the other of the belligerents. On the other hand, a neutral government has a duty to employ the means at its disposal to prevent the fitting out or arming of any vessel within its jurisdiction which it has reason to believe is intended to cruise or engage in hostile operations against a power with which that government is at peace. In recent times the tendency has been towards extending the measure of diligence required of neutral states in exercising surveillance over the acts of their subjects. The movement was commenced by the Neutrality Act of the United States, passed in 1794, and re-enacted, with additions, in 1818. The principles of these American statutes were adopted by Great Britain in the earlier Foreign Enlistment Acts, passed with a view to arming the British government with sufficient powers to enable it to fulfil the obligations of neutrality. But the events connected with the escape of the *Alabama* (see ALABAMA) and other Confederate cruisers during the American civil war revealed the inadequacy of the then existing law of Great Britain on the subject, and led to the passing of the more stringent Foreign Enlistment Act of 1870. In the Treaty of Washington, 1871, Great Britain not only accepted the principle that the failure of a neutral power to fulfil the obligations laid on it by international law gave rise to a claim for redress on the part of the belligerent injured by such negligence, but also consented to the application by the arbitrators of three new rules, known as the Rules of Washington. These rules were substantially adopted as universally binding in the Hague Convention of 1907, dealing with neutral rights and duties in maritime war.

A state may be neutralised in the sense that the condition of neutrality is imposed on it by international agreement. Three European states—Belgium, Luxemburg, and Switzerland—were formerly thus neutralised, their perpetual neutrality being guaranteed. The violation of the neutrality of Belgium by Germany in 1914 was the decisive consideration which led Great Britain, in fulfilment of her obligations under the international treaty, to enter into the Great War. By the Treaty of Versailles, 1919, Belgium and Luxemburg have

ceased to be neutralised states; and at the present time Switzerland is the only European state which occupies a position of guaranteed neutrality.

Neuve Chapelle. See WAR (GREAT).

Neuville, ALPHONSE MARIE DE (1836-85), French painter and illustrator, born at St Omer.

Neuwied, a town of Prussia, on the right bank of the Rhine, 8 miles below Coblenz, was capital of the mediatised principality of Wied; the castle of the princes has a beautiful garden, in which are many Roman antiquities discovered here. The town contains an important institute of the Moravian Brethren, and there are some minor manufactures. Pop. 20,000.

Neva, a river of Russia, flows westward from the south-west corner of Lake Ladoga to the Bay of Cronstadt, in the Gulf of Finland, passing through St Petersburg, and carries to the sea an enormous volume of water (greater than that of the Rhine) from the lakes Ladoga, Onega, Ilmen, and others. Its total length, with windings, is about 40 miles; in places it is over 4000 feet wide, elsewhere the channel is narrowed to 180 feet; and in one or two places the navigation is embarrassed by reefs and rapids. It is frozen on an average from 25th November to 21st April. By the Ladoga Canal the Neva communicates with the vast water-system of the Volga, and so joins the Baltic with the Caspian Sea. In strong westerly winds the waters are dammed back at the mouth, and the delta flooded.

Nevada, one of the Mountain states of the American Union, popularly 'Sage-brush State,' lies between Oregon, Idaho, Utah, Arizona, and California. Its greatest length from north to south is a little less than 500 miles, and its greatest width from east to west is more than 300 miles. In area (110,700 sq. m.) it is the sixth largest state of the Union; in population it is the lowest—(1870) 42,491; (1880) 62,266; (1900) 42,335; (1910) 81,875; (1920) 77,407. Nearly the whole of Nevada is included in the Great Basin (q.v.), once occupied by a great inland sea, and afterwards by several great lakes which have also disappeared. Some of the deepest depressions are yet marked by Walker, Humboldt, Carson, Pyramid, and Winnemucca lakes, and by other 'sinks' and *playas*. The ancient shore-lines are clearly visible in certain places, and the climate, now arid and nearly rainless, was once moist. The soil of the Great Basin at some time produced an abundant vegetation, whereas it is now almost totally unfit for agriculture, frowned upon by barren treeless mountains, and traversed by regions of nearly absolute desert. At present Nevada is a high plateau with an average altitude of 4000 feet, crossed by numerous ranges of mountains which as a rule are parallel and separated by valleys from 5 to 20 miles in width. Some of these valleys are barren and desolate; others, through which the rivers flow, have areas of arable land. The mountains contain rocks of every geological period; many of them are volcanic, and there are striking exhibitions of metamorphic rocks. In the valleys lie the sedimentary deposits of ages mixed with cinders and other volcanic products which fell in many cases on the surface of the extinct lake, and at the mouths of the cañons are vast moraines. The mineral production of Nevada, especially of silver, has been enormous (see COM-STOCK LODE). The production was at first so great as materially to change the value of the precious metals, and to promote Nevada hastily from an uninhabited desert to a state of the Union. Mining is still the chief interest, and the yield of silver, gold, copper, &c., is still considerable. A small area in the north is drained by the Owyhee River,

a tributary of the Snake, and another portion of the state in the south belongs to the Colorado valley. Otherwise Nevada lies wholly in the great basin of interior drainage, where none of the water reaches the sea. The streams disappear in the sand or flow into 'sinks,' salt or brackish lakes, or *playas*, which are shallow mud lakes that evaporate when the supply of water fails. The Humboldt River pursues a winding course of 350 miles. There are numerous hot springs, many of which are surrounded with incrustations of tufa, often in weird and fantastic forms. Some of the lakes are nearly saturated solutions of borax and salts of sodium and potassium, and in the valleys are tracts of glistening alkaline deposits, which mark the beds of extinct lakes.

The atmosphere is dry, remarkably clear in winter, but filled in summer with minute particles of dust, which produce endless and extraordinary effects of colour on the sunlight. The temperature is subject to extremes, and the rainfall is exceedingly light. It nowhere exceeds 15 inches, and scarcely averages more than 5 inches. Some sections receive no rain for several successive years. Sage-brush and other desert plants capable of enduring drought form the native vegetation. It has been estimated that with careful irrigation about 3 per cent. of the land may be successfully cultivated. The Mormons established a few temporary camps in 1848, and in 1850 a settlement was made at Genoa; but the real history of the state begins with the discovery of silver in 1859. Nevada was separated from Utah territory in 1861, and in 1864 was admitted to the Union as a state. There are seventeen counties in the state. The largest town is Reno (population, 12,000), on the Comstock Lode. Carson is the capital. Within the state there are over 2300 miles of railway. The public schools are under the control of a state board of education, and there is a state university at Reno. There are nearly 11,000 Indians in the state, mostly Pah-Utes and Shoshones, and the schools on the reservations are well attended.

Nevers, the capital now of the French department of Nièvre, and formerly of the province of Nivernais, is picturesquely seated on a hillside, 600 feet above sea-level, at the influx of the Nièvre to the Loire, 159 miles by rail SSE. of Paris. The *Noviodunum* of Caesar, it has been the seat of a bishop since 506; its beautiful cathedral, restored in 1879, belongs mainly to the 13th century. The stately *palais-de-justice*, dating from 1475, was formerly the castle of the Dukes of Nevers; and there are also a fine public garden, a bridge of fourteen arches over the Loire, a mediæval gateway, and a triumphal arch (1746) commemorating Fontenoy. The industries comprise the manufacture of cannon, iron cables and chains, porcelain (introduced by Italians about 1565), &c. Pop. 30,000.

Neville, RICHARD. See WARWICK (EARL OF).

Neville's Cross. See DAVID II.

Nevis, one of the Leeward Islands, 2 miles SE. of St Christopher (q.v.), with which it has been since 1882 administratively connected. It is circular, rises in the centre to a wooded ancient crater (3200 feet). The lower slopes are cultivated. Sugar-cane, cotton, coconuts, limes, and oranges are grown. The capital is the port of Charlestown (pop. 1000). Nevis was discovered by Columbus in 1498, and colonised by England in 1628. It was one of the principal slave marts in the West Indies. The island has suffered much at various times from hurricanes and earthquakes. Area 50 sq. m.; pop. 13,000.

Nevis, BEN. See BEN NEVIS.

New Albany, capital of Floyd county, Indiana, is on the north bank of the Ohio River, nearly opposite Louisville. The city is well built, and is the principal manufacturing town in the state. It contains rolling-mills, flour, woollen, cotton, and planing mills, &c. Pop. (1880) 16,423; (1920) 22,992.

New Almaden. See ALMADEN.

New Amsterdam. See NEW YORK, GUIANA.

Newark, (1) a port of entry and the capital of Essex county, New Jersey, is on the Passaic River, 9 miles by rail W. of New York. It is a handsome city, with several beautiful little parks and wide streets shaded with lines of elms. It produces brass and iron work, hardware and machinery, carriages, saddlery, boots and shoes, cotton thread, clothing, jewellery, &c., and has a long line of docks. Newark was settled in 1666 by a colony from Connecticut, and received a city charter in 1836. Pop. (1870) 105,059; (1900) 246,070; (1920) 414,524.—(2) Capital of Licking county, Ohio, off the Licking River (here crossed by four iron bridges), 33 miles by rail E. by N. of Columbus. Stoves and furnaces, boilers, machinery, wagons, flour, woollens, and glass-ware are among its manufactures. Pop. 27,000.

Newark-upon-Trent, a town of Notts, on a navigable branch of the river Trent, 18 miles by rail NE. of Nottingham and 120 N. by W. of London. It is approached from the north by a causeway, $1\frac{1}{2}$ mile long, constructed by Smeaton in 1770, and carried over the flat island formed by the Trent on the west and the Newark branch on the east. The fine parish church, built mainly between 1350 and 1489, has an octagonal spire 223 feet high, and contains a good brass of 1361. Other edifices are the town-hall (1805), corn exchange (1848), hospital (1881), coffee-palace (1882), free library (1882), and grammar-school, founded by Archdeacon Magnus in 1529. Newark has a very important corn-market and great malting industries, besides iron and brass foundries, manufactures of boilers and agricultural implements, and plaster of Paris works. Incorporated by Edward VI., it returned two members to parliament till 1885. Pop. (1851) 11,230; (1921) 16,957. A British town and Roman station, Newark in Saxon times became the seat of a castle, which was rebuilt in 1125 by Alexander, Bishop of Lincoln (hence the name *New Work*), and which long bore the name of the 'key of the north.' King John died in it (1216); and in the Great Rebellion it stood three sieges, in the second of which it was relieved by Prince Rupert (1644), whilst in the third it was surrendered to the Scots by order of Charles I., who had just delivered himself up (5th May 1646). It was then dismantled, and is now represented only by a very picturesque ruin, in a public garden.

New Australia, a pastoral and agricultural settlement in Paraguay, founded in 1893 by an Australian journalist, William Lane, and other Australians, as an experiment in Communism. See Stewart Grahame's *New Australia* (1910).

New Bedford, a city and port of entry of Massachusetts, is on the Acushnet estuary (here crossed by a bridge 4000 feet long), 3 miles N. of Buzzard's Bay and 56 miles by rail S. of Boston. Many of its private residences are very handsome, while the public buildings include a city hall of granite, a custom-house, a public library, and a fine high school. There is a broad drive (4 miles) round Clark's Point, at the extremity of which there is a strong granite fort. For a century (1755-1854) New Bedford was the chief centre of the American whale-fisheries; but this industry

has since declined, and the people have turned their attention mainly to manufactures. Besides several great cotton-mills, the city contains manufactures of drills, cordage, silk, rubber, glass, plated ware, &c. Pop. (1880) 26,845; (1900) 62,442; (1920) 121,217.

New Bern, a city and port of entry, capital of Craven county, North Carolina, is situated at the junction of the navigable Neuse and the Trent (here crossed by a long bridge), 107 miles by rail SE. of Raleigh. It exports cotton, lumber, and early vegetables for the North. It manufactures cotton-seed oil, wood-pulp, &c., and cans oysters. Pop. 12,000.

Newbery, JOHN (1713-67), a London bookseller, intimately associated with Dr Johnson, Goldsmith, Christopher Smart, Smollett, and many other men of letters, was descended from an old bookselling family, and born a farmer's son, in Waltham St Lawrence parish, Berks. He sold general wares at Reading, and about 1744 settled in London as a vendor of books and such medicines as Dr James's Powder—the panacea of Horace Walpole as of Goldsmith. He was the first to publish little books for children, and he was himself, in conjunction with Giles and Griffith Jones (1722-86), and perhaps Goldsmith, part author of some of the best of the series, as the histories of Goody Two-Shoes and Giles Gingerbread and the Travels of Tommy Trip. In 1758 he started the *Universal Chronicle, or Weekly Gazette*, in the numbers of which the celebrated *Idler* was first printed, and in 1760 *The Public Ledger*, in whose early numbers appeared Goldsmith's *Chinese Letters*, later reprinted as *The Citizen of the World*. He had a genius for advertising, even bringing in allusions to his books and wares in the text of his stories. Johnson sketched him humorously as 'Jack Whirler' in No. 19 of the *Idler*. In *The Vicar of Wakefield* he is immortalised as 'the philanthropic bookseller in St Paul's Churchyard, who has written so many little books for children. He called himself their friend, but he was the friend of all mankind.' See Charles Knight, *Shadows of the Old Booksellers* (1865); and Charles Welsh, *A Bookseller of Last Century* (1885).

Newbolt, SIR HENRY JOHN, poet, was born 6th June 1862 at Bilston, Staffordshire, son of the vicar; was educated at Clifton College and at Corpus Christi, Oxford; from 1887 to 1899 practised as a barrister; and from 1900 to 1904 edited the *Monthly Review*. He secured popularity by the patriotic ring and fervour of his verse in *Admirals All* (1897), *The Island Race* (1898), *The Sailing of the Long Ships* (1902), and other volumes, collected later as *Poems New and Old* (1912, 1919). He wrote also plays, prose romances, naval and military histories, *A New Study of English Poetry* (1917), and other works, and edited anthologies.—His daughter, MARGARET CECILIA FURSE, has published poems (*The Gift*, 1919).

New Britain, a manufacturing city of Connecticut, 9 miles by rail SW. of Hartford, engaged in the production of hardware, cutlery, locks, jewellery, hosiery, &c. It is a pleasant city, with large parks, and contains the state normal school. Pop. (1880) 11,800; (1900) 25,998; (1920) 59,316.

New Britain, by Germans called NEU-POMERN, an island of the Bismarck Archipelago, separated from the north-east coast of New Guinea by the Dampier Strait. The interior is almost wholly unknown. In the forest-clad interior there are several volcanoes, active and quiescent, the highest being the Father (7000 feet). The climate is hot and moist. Coconuts, yams, bananas, bread-fruit, betel-nuts, and the like are the chief

products. Fish are caught in great numbers. The natives, cannibal Melanesians, warlike, suspicious, and crafty, make handsome canoes, with sails and outriggers, earthenware vessels, baskets, mats, &c. The sling, stone axe, and spear are their favourite weapons. Area, 9600 sq. m.; pop. 50,000.

See Romilly, *The Western Pacific and New Guinea* (1886); Powell, *Wanderings in a Wild Country* (1883); Parkinson, *Im Bismarck-Archipel* (1887), and *Dreissig Jahre in der Südsee* (1909).

New Brunswick, a province of the Dominion of Canada, is bounded on the N. and NW. by the province of Quebec, from which it is separated by the river Restigouche; on the N. by the Chaleur Bay; E. by the Gulf of St Lawrence and Northumberland Straits—the latter separating it from Prince Edward Island; S. by the Bay of Fundy and part of Nova Scotia; and on the W. by the state of Maine, the boundary with the latter being the St Croix and St John rivers. It has an area of 27,987 sq. m.—rather smaller than Scotland. Its coast-line is 600 miles in length, interrupted only at the point of juncture with Nova Scotia, where an isthmus not more than 15 miles broad connects the two provinces, and divides the waters of Northumberland Straits from those of the Bay of Fundy, across which isthmus is the abandoned Chignecto Ship-railway. The surface of the country is generally undulating. There are low hills skirting the Bay of Fundy and the rivers of St John and Restigouche. A feature of the coast-line is the number of fine harbours, of great value for exporting the timber for which the country is famous.

Several important rivers traverse the province; among the principal is the St John, 450 miles in length, and navigable for vessels of 100 tons to Fredericton, the capital of the province, 80 miles from the sea. Above this point smaller craft ascend for 125 miles. The country drained by the St John and its tributaries comprises about nine million acres in New Brunswick, as well as eight million in Quebec and the state of Maine. The Miramichi River, 220 miles long and 7 miles wide at its mouth, is also navigable for some distance. The Restigouche is 3 miles wide at its entrance into the Chaleur Bay, and over 200 miles in length. The lakes are numerous but small, the largest being Grand Lake, 30 miles long and 3 to 7 miles wide, communicating with the St John River, 50 miles from the sea.

The population of the province at the census of 1881 was 321,129; of 1921, 387,876. In 1921 there were 170,531 Catholics, 86,254 Baptists, 47,020 Anglicans, 41,277 Presbyterians, and 34,872 Methodists. The population included 131,664 persons of English origin; 68,670 Irish; 51,308 Scottish; 1331 American Indians; 1698 Germans; 121,111 French. The principal cities are St John (47,166) and Fredericton, the capital (8114). The provincial government is administered by a lieutenant-governor, assisted by an executive council, and a legislative assembly of forty-eight members, elected by the people. The province sends ten members to the senate, and eleven to the Dominion House of Commons.

Like that of many other parts of Canada, the climate of New Brunswick is subject to extremes of heat and cold. If, however, the climate of a country is to be judged by its effects on animal life, that of New Brunswick may be pronounced one of the best in the world.

The educational institutions supported by law are the Provincial University at Fredericton, the training or normal school for teachers, and a complete system of free common schools. There are also universities at Sackville (Methodist) and St Joseph (Roman Catholic).

Agriculture is the chief industry in New Brun-

wick. Except a portion of country adjacent to the coast of the Bay of Fundy the soil is very fertile, and almost every kind of grain and roots can be grown. Attention has been paid to live-stock both by the government and private breeders; and the manufacture of butter and cheese has greatly increased. The province, owing to its cheap coal and proximity to the markets of the world, has also many advantages as a manufacturing country. The principal manufactures are sawn lumber, leather, cotton and woollen goods, wooden-ware, paper, and mill machinery. The manufacture of wood-pulp from spruce, a comparatively new industry, has grown to great proportions. There are indications of considerable mineral wealth, and a number of mines are being successfully worked. The fisheries are very valuable.

It is generally held that New Brunswick, as a part of Nova Scotia, was ceded by France to Great Britain by the treaty of Utrecht in 1713. The boundaries of Nova Scotia, however, were not well defined at that time, and the country along the St John River remained a subject of dispute which was not finally settled until the treaty of Paris in 1763 conceding and guaranteeing to Great Britain, in full right, Canada with all its dependencies. When in 1755 the memorable expulsion of the Acadians from Nova Scotia took place many of these people retired to what is now known as New Brunswick, and settled along the upper St John River, the Miramichi, and in the eastern parts of the province. The first British settlers in the province emigrated from Scotland to the Miramichi district in 1764; and in 1783, at the close of the American revolution, when the exodus of the loyalists from the United States took place, a large body settled near the present city of St John and along the St John River. For the map, see CANADA.

New Brunswick, capital of Middlesex county, New Jersey, is at the head of navigation on the Raritan River, 31 miles by rail SW. of New York, and is the terminus of the Delaware and Raritan Canal. It contains Rutgers College (1771), connected with which are the theological seminary of the Dutch Reformed Church, an observatory, and a state agricultural college and model farm. New Brunswick is noted for its great india-rubber factories, and has also iron and brass foundries, and manufactures of hosiery, needles, paper-hangings, &c. Pop. 33,000.

Newburgh, a royal burgh of Fife, near the Firth of Tay, 11 miles ESE. of Perth. It arose in connection with the neighbouring Benedictine abbey of Lindores (c. 1196); and near it is also the famous Macduff Cross. Pop. 2000.

Newburgh, a city of Orange county, New York, is on the west bank of the Hudson (here $1\frac{1}{2}$ mile wide), 57 miles by rail N. of New York, amid the grand scenery of the Highlands. Its handsome edifices, villas, and gardens, rising 300 feet from the river, command a noble prospect. The city has, besides foundries, shipyards and powder-mills, manufactures of woollen and cotton goods, machinery, felt, plaster, &c. Large quantities of butter, grain, flour, and coal are shipped. Newburgh was the scene of the disbandment of the American army, 23d June 1783; and 'Washington's Headquarters' is preserved as the property of the state. Pop. 30,000.

Newbury, a thriving market-town of Berkshire, on the 'swift' Kennet, 17 miles W. by S. of Reading and 55 from London. Its gray old church, restored in 1867, is a fine Perpendicular edifice, with a noble tower added in 1510 by John Winchcombe or Smallwoode, otherwise 'Jack of Newbury,' a famous clothier, who sent a hundred of his own

men to fight at Flodden. The large Italian corn exchange was built in 1862, in which year was started a great yearly wool-market; later are the handsome municipal offices and the grammar-school, though this claims King John for its founder (1216). Newbury—'new' only as distinguished from the old Roman station of *Spinæ* (now Speen)—besides has many ancient and wealthy charities. It was incorporated by Elizabeth in 1596. Pop. (1801) 4275; (1851) 6574; (1921) 12,290. Two hard-fought battles took place here, one between Charles and Essex, on 20th September 1643; the other between Charles and Manchester, on 27th October 1644. The advantage of the first was, on the whole, on the side of the king, but it cost the lives of Lords Falkland (q.v.), Carnarvon, and Sunderland, to whom a memorial was erected in 1878. The second would have been a decisive royalist defeat but for Manchester's hesitancy.

Newburyport, a city and port of entry of Massachusetts, on the south bank of the Merrimack, 3 miles from its mouth, and 37 miles by rail NE. of Boston. A long, shady High Street, with a pond of six acres, is its chief ornament. Cotton, shoes, combs, &c., are manufactured. Pop. 16,000.

New Caledonia, an island of the South Pacific Ocean, belonging to France, and lying midway between the Fiji Islands and the east coast of Queensland. The Loyalty Islands, Isle of Pines, and some others, with a total area of 1250 sq. m., are politically dependent upon New Caledonia. This principal island is about 250 miles in length, 30 in average breadth, and has an area of 6450 sq. m. The long axis runs from north-west to south-east; the interior is greatly broken by irregular mountain-chains (highest point, Mount Humboldt, 5380 feet). Below the bare summits are well watered, thickly wooded, and vegetated slopes. The entire island is surrounded by coral-reefs. There are good harbours on the east coast, but the only one used is Nouméa, with railway connections on the south-west coast. The vegetable products include coconuts, coffee, maize, tobacco, manioc, rice, cotton, fruits, &c. But the most valuable natural products are minerals, especially nickel, with chrome, copper, manganese, cobalt, antimony, &c. There are several useful timber-trees. Cattle-raising is of some importance. Turtle and fish are abundant. Locusts frequently devastate the crops. Besides the smelting of the minerals, meat is preserved and sent to France, and some soap and tapioca are manufactured. Nickel, cobalt, chrome ore, silver, lead ore, preserved meat, copra, coffee, &c., are exported. The total population is about 50,000, of whom some 28,000 are Melanesians and Polynesians, 19,000 Europeans. Nouméa (the capital) has a pop. of 10,000. The island was discovered by Captain Cook in 1774, and was annexed by France in 1853. She used it as a convict station, but the practice of sending convicts there was practically abandoned by the end of the 19th century. The aborigines are a mixture of two types, one resembling the Polynesians, the other the Papuans. They were formerly cannibals, and delighted in war, yet were hospitable, and skilful tillers of the soil. They live now chiefly on vegetable food. Leprosy is a scourge amongst them. See French works by Lemire (1878-1904), Bernard (1895), and Vallet (1920).

New Castle, capital of Lawrence county, Pennsylvania, on the Shenango River, 50 miles by rail NNW. of Pittsburgh, contains a college, large rolling-mills, foundries, and manufactures of nails, furnaces, and flour; pop. 45,000.

Newcastle, a port of New South Wales, 75 miles NE. of Sydney by rail, at the mouth of the

Hunter River. It is the chief port of the north coast, coal and wool the main exports. The harbour, which is defended by a fort, is dangerous during storms from the ESE. Pop. with suburbs, 90,000.

Newcastle, DUKES OF. See CAVENDISH and PELHAM.

Newcastle-under-Lyme, a parliamentary and municipal borough of Staffordshire, on the Lyme brook, 16 miles NNW. of Stafford. Pop. (1801) 4604; (1921) 20,418, parl. borough 64,409. The aspect of the town was much improved by the widening of the main thoroughfares, and the erection of public buildings, notably the town-hall (1890) and the high school (1876). The latter was reconstructed under a new scheme in 1874 from the amalgamation of various ancient charities (the earliest founded 1602). The parish church, partly Early English and partly Decorated, was rebuilt in 1876 from designs of Sir Gilbert G. Scott, and has a quaint old square tower of red sandstone with pinnacles, and a fine peal of bells. The manufactures include brewing, malting, and the making of fustians, chemicals, paper, and army clothing, whilst the surrounding district is noted for its potteries and coal-mines. Of the castle, from which the town derives its name, all traces have entirely disappeared; it was built by Edmund, Earl of Lancaster, the youngest son of Henry III. Newcastle returned two members to parliament from 1353 to 1885, since that time one.

Newcastle upon Tyne, a city and county of itself, seated on the north bank of the Tyne, 275 miles from London. The city, the seat of a bishopric founded in 1882, has had a Lord Mayor since 1906, and returns four members to parliament. Pop. (1801) 28,294; (1841) 71,850; (1901) 215,328; (1921) 274,955. The annexation in 1904 of the urban districts of Benwell and Fenham and part of the rural district of Kenton increased the area of the city by 50 per cent.

During the Roman occupation of Britain the high ground overlooking the river in the neighbourhood of the castle was the site of the military station of Pons Ælii. The 'Roman wall' would probably form its northern boundary. Soon after the abandonment of Pons Ælii by the Romans the Angles took possession of it. Subsequently it appears to have been a monastic settlement, and at the time of the Conquest was known as Monkchester. Pandon, which until 1299 was a vill quite distinct from Newcastle, is supposed to have been the place where, about 653, Pæda, son of Penda, king of the Middle Angles, and Sigebert, king of the East Angles, were baptised by Bishop Finan. When the Conqueror arrived at Monkchester in 1072 there was nothing to be seen of the bridge above water, and the town was too small or impoverished to victual his army. Robert Curthose, on his return from an expedition against Malcolm in 1080, constructed a fortress here, which was named the New Castle. The south postern is probably a fragment of his work. William Rufus is stated—on doubtful authority—to have rebuilt the castle, and to have granted to the inhabitants of the growing town many privileges and immunities. He besieged the castle in 1095. The present keep—one of the most perfect examples of a Norman stronghold in the kingdom—was built between 1172 and 1177 at a cost of £911, 10s. 9d., and the Great Gate of the castle—the Black Gate as it is now called—in 1247, at a cost of £514, 15s. 11d.

In the time of the first three Edwards the town was enclosed by a wall, 8 feet thick and over 12 feet high, which embraced in its circuit the monasteries of the Black, the White, and the Grey Friars, the Benedictine nunnery of St Bartholomew, together with the vill of Pandon. The levies for

the Scottish wars were usually directed to assemble at Newcastle. In 1644 Newcastle, which had declared for the king, was besieged for ten months by the Scots under General Leslie. Its resistance is commemorated in the motto 'Fortiter Defendit Triumphans.' Events of tragic importance in the annals of the town were the visitations of Asiatic cholera in 1831 and 1853, and the great fire which destroyed much of the old town in 1854.

The city occupies a striking and picturesque site, being built for the most part on steep slopes and gently rising ground. It abounds in contrasts, such as the grim old keep and the High Level Bridge; the modern Grey Street and the ancient Side; the stately stone buildings erected by Grainger and the half-timbered Elizabethan houses with projecting stories and latticed casements; the Elswick Works, considerably over a mile in extent, and Jesmond Dene, one of the loveliest ravines in the country; the closely-packed hillsides and the rolling expanse of common called the Town Moor.

The principal remains of antiquity in Newcastle are the Norman keep; the Black Gate; the cathedral of St Nicholas; the churches of St John and St Andrew; portions of the Edwardian walls, with the Durham, Heber, Mordaunt, and Plummer towers, and the Sally-port Gate; part of the Black Friars Monastery; fragments of the houses of the Austin Friars and the Friars of the Sac; and several mansions of the 16th and 17th centuries. The church of St Nicholas, now the cathedral, is said to have been founded by Osmund, Bishop of Salisbury, in 1091. This early structure was destroyed by fire in 1216. The present building belongs to the Decorated and Perpendicular periods; the nave and transepts dating from 1359, the chancel from 1368, and the tower with its beautiful architectural crown from about 1435. All that remains of the previous edifice is some masonry above the arcades, together with an Early English pillar built up in the north-east pier. The reredos, erected in 1888, is of fine unpolished Uttometer alabaster with splayed screens of Caen stone. In canopied niches around the central figure of Christ are statues of Northumbrian saints and the four evangelists. St John's Church, built in the latter part of Henry I.'s reign, contains much of the original Norman work, with Early English, Decorated, and Perpendicular additions. St Andrew's Church dates from about 1175 to 1185, and retains some interesting Transitional features. All-Saints' Church was rebuilt in 1786–90 on the site of the church of All-Hallows, founded in the 12th century. There are many other places of worship in the city connected with the Established Church; the Roman Catholics have several churches, one being the cathedral of St Mary, erected in 1844 from the designs of Pugin; and the various other religious bodies are well represented.

The central part of Newcastle with its stately and ornate buildings is a monument to the genius of Richard Grainger (1798–1861), a man of lowly origin, educated at St Andrew's Church School, who, by his vast building schemes, quite changed the appearance of his native town. Grey Street and Grainger Street, built in 1834–38, are the finest thoroughfares in the city. Monuments have been erected to Earl Grey (1838), George Stephenson (1862), Queen Victoria, Lord Armstrong, Joseph Cowan, as well as South African and Great War Memorials. The town-hall, built in 1863, stands near the cathedral. Associated with it are the corporation offices and the corn-market. Other public buildings are the guildhall and exchange on the Sandhill, the former (which occupies the site of the hospital of St Catharine) dating from 1658, the Moot Hall (1810), the general post-office (1876), the central police-courts (1874), the gaol

(1823-28), the Wood Memorial Hall (1870), the Trinity House (chapel, c. 1651; hall, 1721; almshouse, &c., 1782-95), the Old Assembly Rooms (1774-76), the Grand Assembly Rooms, the (branch) Bank of England (1834), the Royal Arcade (1831-32), the Butchers, Fruit, Flower, and Vegetable Markets (1835), covering an area of 13,906 sq. yds., and the barracks (1806). There are several theatres in Newcastle. The museum of the Natural History Society, erected in 1883-84, contains valuable collections of British birds, fossils from the Coal Measures, and a unique series of Bewick's drawings. The Literary and Philosophical Society (1793) has an important and voluminous library. The public library (1881) with its various branches is well stocked.

Institutions in Newcastle affiliated to the university of Durham are the College of Medicine (1851), the College of Science (1871), and the Armstrong College (1906). The Royal Free Grammar-school, founded in 1525, stood from 1870 in Westmoreland Road. It now occupies new buildings of a most complete kind, with large playing-fields at Jesmond. Among the various benevolent institutions in Newcastle are the Royal Victoria Infirmary (1751), now situate on the Castle Leazes, the Hospital of the Holy Jesus (1681), the Keelmen's Hospital (1701), the Trinity Almshouses (incorporated 1492), the Northern Counties Institution for the Deaf and Dumb (1861), the Fleming Memorial Hospital (1887), and the Northern Counties Orphan Institution (1876), the Home for Crippled Children, Gosforth (1888), the Maternity Hospital, the Eye Infirmary, the Throat, Nose, and Ear, and other hospitals.

The public pleasure-grounds of Newcastle are Town Moor (987 acres), Castle Leazes, and Nuns Moor, the Leazes, Elswick, Brandling, Heaton, and Armstrong Parks, the Cruddas recreation-ground, and Jesmond Dene. Armstrong Park and Jesmond Dene Newcastle owes to Lord Armstrong.

Newcastle is connected with Gateshead by four bridges: (1) the High Level Bridge, described in the article BRIDGE. (2) The Swing Bridge, erected 1868-76, on the site of the Roman, mediæval, and 18th-century bridges. (3) The Redheugh Suspension Bridge, erected 1868-71, is 1453 feet in length, its height from high-water mark to the under side of the arch being 87 feet. (4) A railway bridge opened in 1906 (see BRIDGE). A new high-level bridge for pedestrian and vehicular traffic is in course of construction. The port of Newcastle is a very ancient and important one. The river is navigable by large vessels to Elswick. Since it came under the jurisdiction of the Tyne Commissioners improvements on a large scale have been made. The corporation quays are 6800 feet in length, and vessels of large size can be moored in safety. As early as the 13th century the chief trade of Newcastle was coal. Thereafter, with the increasing development of the coalfields of Northumberland and Durham, especially after the coming of a new industrialism in the later 18th and early 19th century, the trade grew progressively in importance, the town being famed proverbially as a place of coal export. Among other exports relatively of minor importance are various local manufactures (see below), together with many of the industrial products of northern England. Imports are chiefly of foodstuffs and of raw materials for the large industrial region for which the town is the centre.

Apart from the mining of coal in the neighbourhood, shipbuilding and engineering (marine and locomotive engines and machinery) are the primary industries of Newcastle, the town in both these activities ranking among the first in the country. The production of heavy ordnance is also of much

importance. Stimulated by an abundant fuel supply, there is a great variety of lesser manufactures—chemicals, colours, tar products, glass, bricks, fireclay goods, earthenware, iron and steel and lead goods, grindstones, &c. The most important works at Newcastle are those of Sir W. G. Armstrong, Whitworth & Co., Limited, founded in 1847. They comprise blast-furnaces, engine-shops, foundries, and steel-works, with shipbuilding yards at Elswick and Walker. The firm builds many ships of war. From the engine-works of R. Stephenson & Co. (founded by George Stephenson in 1824), and R. W. Hawthorn, Leslie & Co., locomotive and marine engines have been sent to all parts of the world. Newcastle is the birthplace of Lords Eldon and Collingwood, Mark Aken-side, Charles Hutton the mathematician, and Lord Armstrong.

See Gray's *Chorographia* (1649); and the histories of the town by Bourne (1736), Brand (1789), an anonymous writer—supposed to be the Rev. John Baillie (1801), E. Mackenzie (1827), Welford (3 vols. 1884-87), R. J. Charleton (1885), J. R. Boyle (1890), and Hearnshaw, *Newcastle upon Tyne* (1924).

New Church. See SWEDENBORG.

New-chwang, or NIU-CHWANG, a city of Manchuria, on the river Liao, 20 miles from its mouth and 120 from Mukden. By the treaty of Tientsin (1858) New-chwang was opened to foreign trade. From the accumulation of alluvial soil in the lower reaches of the river vessels are obliged to load and discharge at Ying-tzu, at its mouth. It is there the Europeans are settled, and they call Ying-tzu by the name of the treaty-port New-chwang—which latter is now a greatly decayed place. Ying-tzu exports beans, silk, ginseng, skins, horn, oil, rice, millet, and coal. The port, which is closed four or five months with ice, was captured by the Japanese in 1895; but Russia, taking practical possession of Manchuria (q.v.), connected New-chwang with the Siberian railway, and dominated till the city was again taken by the Japanese in 1904. Pop. 60,000.

Newcomb, SIMON, astronomer, was born at Wallace, Nova Scotia, 12th March 1835, graduated in 1858 at the Lawrence Scientific School at Harvard, was a teacher in Maryland, and in 1861 became a professor of Mathematics in the United States navy. He was appointed at once to the naval observatory at Washington, and in 1877 was placed at the head of the office of the official *American Ephemeris and Nautical Almanac*. He organised the government expedition to observe the transit of Venus in 1874, and in 1882 observed the transit at the Cape of Good Hope. In 1884 he undertook, in addition, the duties of a chair in the Johns Hopkins University. He made notable additions to astronomical science. Not to speak of tables of the constants of astronomy, of the motions of the moon and of eight major planets, and hundreds of articles in scientific journals, his publications include *Popular Astronomy* (1878); *Calculus* (1884); *Principles of Political Economy* (1887); *Elements of Astronomy* (1900); *The Stars, a Study of the Universe* (1902); *Astronomy for Everybody* (1903); *Reminiscences of an Astronomer* (1903); *Compendium of Spherical Astronomy* (1906). He died 11th July 1909.

Newcomen, THOMAS, the inventor of a Steam-engine (q.v.), was born at Dartmouth sometime in the month of February 1663, and died in London in August 1729. In 1705, along with Cawley, a Dartmouth glazier, and Savery, the manager of a Cornish mine, he obtained a patent for what is now known as the atmospheric steam-engine. Some six years later his invention was brought into use for pumping water out of mines.

Newdigate, SIR ROGER (1719-1806), was born and died at Arbury in Warwickshire, having sat for many years in parliament as member for Middlesex and the university of Oxford. He was a great antiquary, but now is chiefly remembered as the endower of the Newdigate prize poem at Oxford, winners of which have been Heber (1803), John Wilson (1806), Milman (1812), Hawker (1827), Lord Selborne (1832), Faber (1836), Stanley (1837), Ruskin (1839), Shairp (1842), M. Arnold (1843), Sir E. Arnold (1852), J. A. Symonds (1860), W. J. Courthope (1864), W. H. Mallock (1871), Sir Rennell Rodd (1881), Laurence Binyon (1890), and Lord Warkworth (1892).

New England, a collective name given to the six Eastern States of the United States of America—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut—embracing an area of 65,000 sq. m. The people, distinctively known as Yankees, are celebrated for industry and enterprise. The joint population in 1920 was 7,400,000; this is almost one-fourteenth of the entire population of the republic, while the area of New England is less than one-fiftieth of the total area of the United States. For the influence of the Puritans who settled here, see Fiske, *The Beginnings of New England* (1889).

New Forest, a triangular district of south-west Hampshire, 9 miles SW. of Southampton, bounded W. by the river Avon, S. by the Solent and English Channel, and NE. by Southampton Water. It measures about 14 by 16 miles. The district seems to have been wooded from the earliest times; but its present name dates from the year 1079, when the Conqueror made a 'mickle deer-frith here,' afforesting the manors, lay and religious, but without expropriating the owners or removing homes or churches. This afforestation was enforced by the savage 'Forest laws,' and regarded as a piece of detestable tyranny; and the violent deaths met by two of his sons (one killed here by a stag, the other by an arrow) were looked on as judgments. The deer were removed under an act of parliament (1851); and under another of 1877 the New Forest now is managed by the court of Verderers as a public pleasure-ground and cattle-farm. Enclosed plantations occupy about one-fourth of the entire area, the remainder being open woodland, bog, and heath. The principal trees are oaks and beech. The former were once much used as timber for the navy; the mast of the latter still feeds large herds of swine. There is also a herd of small, rough-coated ponies. The hollies, the rhododendrons, and therewith the general absence of underwood, give a beautiful park-like aspect to the forest, points within which or on whose verge are Lyndhurst, Beaulieu, and Lymington.

Newfoundland (*Newfundland'*), an island and British dominion in North America, not incorporated with the Dominion of Canada, lies at the mouth of the Gulf of St Lawrence. In shape the island resembles an equilateral triangle, of which Cape Bauld on the north, Cape Race on the south-east, and Cape Ray on the south-west form the angles. It is 370 miles in length, 290 miles in breadth, and has an area of 40,200 sq. m.—a fifth less than England. 'The coast of Labrador from the entrance of Hudson Strait to a line to be drawn due north and south, from Anse Sablon on the said coast to the fifty-second degree of north latitude, and all the islands adjacent to that part of the said coast of Labrador,' is claimed as constituting a dependency of Newfoundland. The boundary with Quebec is disputed. Quebec in 1925 refused to buy Newfoundland's Labrador territory, in whole or in part. During the fishing season in each year about 30,000 in-

habitants of Newfoundland visit Labrador, and live about its harbours, either on shore or in their vessels, for about three months in each year. The population of Newfoundland with its part of Labrador (pop. 3634) amounted in 1901 to 220,249; in 1921 to 263,033 (including 3774 in Labrador). Of these 86,576 were Roman Catholics, 84,665 Anglicans, and 74,207 Wesleyan Methodists.

The island, as seen from the sea, presents a wild and sterile appearance. Its surface is diversified by mountains, ponds, and lakes. The mountains in the Avalon Peninsula (stretching south-east from the main portion of the island, and connected with it by an isthmus of only about 3 miles in width) rise in some cases to over 2000 feet above sea-level. The number of the lakes and 'ponds' is remarkable, and it has been estimated that about one-third of the whole surface is covered with fresh water. The coast-line is everywhere deeply indented with bays and estuaries. These bays vary in length from 25 to 70 miles, are of great breadth, and are lined—as indeed the whole coast is—with excellent harbours. The rivers are narrow and winding. Much of the soil is productive, and there is considerable cultivation along the seaboard of the settled districts, but careful exploration has shown that the best land and timber are in the river-valleys and upon the west coast. Large tracts of very good timber, chiefly pine and spruce, exist in several parts of the island. The great body of the people being employed either in the fisheries or in establishments connected with them, little attention used to be paid to the culture of the soil. In 1845 the only crops raised were oats and hay; but now apples, small fruits, potatoes, turnips, hay, carrots, clover, barley, and oats are cultivated with success. The island possesses many minerals. Iron is worked mainly as yet on the east coast. The chief seat of copper-mining is around the shore of Notre Dame Bay. The ore is found in connection with the serpentine rocks, which are spread over an area of 5000 sq. m. Gold has been found. Rich deposits of lead ore exist in several places. Gypsum and marbles are plentiful. Roofing-slate is found. Coal and iron exist side by side near the west coast, and coal in the interior. Mining in several parts of the island was long hampered by claims set up by the French to a right to use the strand for drying fish 'free from interruption' by the colonists. A great variety of valuable fish is found in the waters of the colony and its dependency, but cod, herring, and salmon are the most important. The capture of seals (harp and hood) and the canning of lobsters also add to the resources of the Newfoundlanders. The skins are sent to the United States and Great Britain; the 'fat' is made into seal-oil, which is used for soap-making, lighting, and lubricating. There are fine pine-forests in the north, and extensive sawmills and pulp and paper factories have been established. The schools are denominational (Church of England, Roman Catholic, and Methodist).

The people chiefly depend for a livelihood upon the product of the cod-fisheries, of which there are three distinct branches—namely, the Labrador fishery, the shore fishery, and the bank fishery. Dried cod-fish and cod-oil are exported. The shore fishery is prosecuted along the whole coast-line in Newfoundland, and is the mainstay of the very large portion of the population who from poverty, age, or disinclination refrain from going either to the Labrador or bank fishery, or divide their time between farming and fishing. The bank fishery is prosecuted upon the Banks, so called, which lie to the southwards of Newfoundland. These Banks are submarine plateaus extending over a tract averaging about 600 miles in length and 200 miles

in breadth. The depth of water over the Banks varies from 100 to 600 feet, and the most productive ground is known as the Grand Bank. American, Canadian, and French fishermen also resort to these Banks to fish, the French using their islands, St Pierre and Miquelon, as a base of operations. After cod the chief export is pulp and paper; next comes iron ore.

The principal imports come from Canada, the United States, and Britain; the principal exports go to Britain, Canada, Spain, Portugal, the United States, Italy, and Brazil.

The trans-insular railway was completed in 1897, with branches to important towns and settlements. The total length of railways is about 950 miles. Communication between coast towns and with the continent is maintained by a fleet of excellent steamers in connection with the railway.

The present form of government, established in 1855, consists of the governor, an executive council or cabinet, a legislative council (appointed by the crown), and a general assembly of thirty-six members (elected by the people). Every male of twenty-one years of age, a British subject and two years a resident in the colony, is entitled to vote at elections.

Of the Beothucks who inhabited Newfoundland before the Micmacs and the white men came, little is known. A very tall, somewhat fair race, they hunted and fished, smeared themselves with red ochre, carved skilfully, used stone adzes and utensils of birch-bark and soapstone but no pottery, and were not quite extinct till 1829. The early history of Newfoundland is involved in obscurity. It was discovered 24th June 1497 by John Cabot, and the event is thus noticed in the accounts of the privy-purse expenditure: '1497, Aug. 10. To hym that found the New Isle, £10.' It was visited by the Portuguese navigator, Gaspar de Cortereal, in 1500; and within two years after that time regular fisheries were established on its shores by the Portuguese, Biscayans, and French. In 1578, 400 vessels, of which fifty were English, were engaged in the fishery. Sir Humphrey Gilbert (q.v.), with his ill-fated expedition, arrived in St John's Harbour, August 1583, and formally took possession of the island in the name of Queen Elizabeth. In the return voyage the expedition was scattered by a storm, and the commander lost. In 1621 Sir George Calvert (afterwards Lord Baltimore) settled in the great peninsula in the south-east, and named it the Province of Avalon. The history of the island during the 17th and part of the 18th century is little more than a record of rivalries and feuds between the English and French fishermen; but by the treaty of Utrecht (1713) the island was ceded wholly to England, the French retaining certain privileges in connection with the catching and drying of fish on the coast extending from Cape Bonavista on the east to Point Riche on the west. By the treaty of Versailles (1783) the boundaries were so changed as to extend from Cape John on the east to Cape Ray on the west, and at the same time the French were promised 'freedom from interruption by the competition of the British.' Friction arose over disputed rights, but, under the Anglo-French Convention (1904), France renounced the privileges given by the treaty of Utrecht, but retained for her subjects, on an equality with British subjects, rights of fishing within the treaty waters in the fishing season. In 1886-1904 French fisheries on the Banks were crippled by an act restricting the taking and export of bait from Newfoundland waters. By the treaty of 1818 American fishermen enjoyed certain rights in these waters. In 1905-6 acts of the colonial government imposing restrictions upon American vessels brought about a dispute with the

United States almost as soon as that with France had been settled. The Hague Tribunal decided in 1910 that Great Britain had a right to make reasonable regulations. If necessary a mixed commission should determine what is reasonable.

See J. G. Millais, *Newfoundland and its Untrodden Ways* (1907); W. Fraser Rae, *Newfoundland to Manitoba*; Murray and Howley, *Geological Survey of Newfoundland* (1881); Hatton and M. Harvey, *Newfoundland* (1883); M. F. Howley, *Ecclesiastical History of Newfoundland* (1888), and *French Treaty Rights* (1890); J. P. Howley, *The Beothucks* (1915); Prowse, *A History of Newfoundland*; Lord Birkenhead, *History of Newfoundland* (1920). See also LABRADOR; and for map, see CANADA.

Newfoundland, a breed of dogs originally introduced into England from the island of Newfoundland, where they were used for draught purposes. As the mastiff at that time was scarce, and the St Bernard had not yet appeared in England, the Newfoundland became exceedingly common, but has since been eclipsed in popularity by these breeds. The Newfoundland is a large and imposing dog, mild in expression, but showing great strength. The head should be large, with ears falling close; neck long, if possible; loins strong and well ribbed up, a point seldom seen; tail long and powerful, as it is much used in swimming; coat long and wiry; colour, black without any white markings. Much discussion was caused by Landseer's well-known picture of a black and white dog entitled 'A Distinguished Member of the Humane Society' (1838). An attempt was made to prove that the black and white dog was the true Newfoundland; but it is now generally regarded as a cross from the black. The black and white variety, now known as the Landseer Newfoundland, has been kept pure for many generations; it is now almost as pure, and certainly as handsome, as the original variety. The Newfoundland is a splendid water-dog, and takes to the sea at an early age. He is also a natural retriever, and, though himself too heavy for field work, has been extensively used to found the ordinary retriever. From his formidable appearance, combined with docility and intelligence, he makes a capital watchdog, for which purpose he is extensively used.

Newgate, a historical London prison, stood at the western extremity of Newgate Street, opposite the Old Bailey. The exterior presented high dark stone walls, without windows. It was long the chief criminal prison of city and county, but it ceased to be a debtors' prison in 1815, and after 1849 it was only used for prisoners awaiting trial. The earliest prison here was in the portal of the *new gate* of the city as early as 1218; and hence the name. About two centuries afterwards it was rebuilt by the executors of Sir Richard Whittington, whose statue with a cat stood in a niche, till its destruction by the great fire of London in 1666. The edifice—that best known in history—was re-erected in 1780, but the new buildings were greatly damaged by fire in the Gordon Riots of that year (see Boswell's *Johnson* under that date), when 300 prisoners, felons as well as debtors, were released and let loose upon the public. This awful scene is described by Dickens in *Barnaby Rudge*. After the passing of the Prisons Bill in 1877 Newgate, being considered a very costly and redundant establishment, was gradually disused, and in 1902-3 was completely demolished. The *Newgate Calendar* contains biographical notices of the most notorious murderers, burglars, thieves, and forgers who have been confined within its walls. See Griffiths, *Chronicles of Newgate* (1884); Ch. Gordon, *The Old Bailey and Newgate* (1903).

New Granada. See COLOMBIA.

New Guinea, formerly known as Papua (Papoo'a), an island of Australasia, the largest in the world except the Australian continent, from which it is separated by the shallow island-studded Torres Strait, 80 to 90 miles wide at its narrowest part. There is now no doubt that the two regions at one time, probably during the Miocene epoch, formed continuous land, and an upheaval of less than sixty fathoms would suffice again to unite them. The hundred-fathom line, as determined by Wallace, would also include the insular groups of Jobi, Biak, Suk, Mafor (Nufor), and Amberpon in Geelvink Bay; Aru, near the south-west coast; Mysol, Salwatty, Batanta, and Waiju at the north-western, and the Louisiade and D'Entrecasteaux Archipelagoes at the south-eastern extremity of New Guinea. But elsewhere the mainland is washed by deep waters, ranging from 500 to 1300 fathoms on the south-eastern and northern seaboard. It is disposed in the direction from north-west to south-east, stretching from Cape Goede Hoop ('Good Hope'), just south of the equator ($0^{\circ} 19' S.$ and $132^{\circ} 30' E.$), for about 1500 miles to South Cape, over 700 miles below the equator ($10^{\circ} 34' S.$

and $150^{\circ} 48' E.$). But owing to its extremely irregular shape, somewhat resembling a huge saurian, the width varies from under 20 miles at the narrowest parts of both extremities to 480 miles at the broadest part, about $141^{\circ} E.$ long., giving a total area roughly estimated at 330,000 sq. m., or six times as large as England. The island thus forms three somewhat distinct geographical divisions—a large central mass from which two peninsulas project south-east and north-west. The south-east peninsula is defined by Huon and Papua Gulfs on the north and south coasts, while the north-west peninsula is separated into two secondary members by the Macuer Inlet, which penetrates from the south-west side to within 20 miles of Geelvink Bay on the north-west coast.

Much of the interior is still a *terra incognita*; but the more salient physical features of the island have already been roughly determined. It is essentially a mountainous and even an alpine region, being traversed in its entire length by lofty ranges, by far the highest in the Oceanic world, and in some places rising more than 1000 feet above

the snow-line. These ranges, which in the two peninsular regions form single continuous systems, develop in the broader central parts two or more parallel chains with a general south-easterly trend, at many points approaching close to the coast-line, and elsewhere enclosing extensive rugged plateaus. Thus, the Arfak Hills of the north-west peninsula (10,000 feet) are continued in the central region by the Charles-Louis range, which, varying in height from 4000 feet to 9000 feet, stretches into the Snowy (Nassau) range, where Mount Wilhelmina, Mount Carstenz, and Mount Idenberg rise to over 15,000 feet. Parallel with this chain runs the northern coast range, known as the Finisterre Mountains (11,500 feet), which terminates eastwards in an imposing headland projecting in the direction of New Britain, and enclosing Huon Gulf on the north side. Between these two chains run the Bismarck and Krätke ranges (10,000 feet), the latter discovered in 1887 by Dr H. Zöller. About the same time Count Pfeil, administrator of German New Guinea, penetrated from the north coast still farther inland in search of expansive tablelands suitable for settlement; but he found the

whole surface broken into a confused mass of steep mountains composed mostly of old sedimentary rocks—altogether 'a rugged, hopeless region' intersected by deep gorges, but few open river-valleys.

All these mountain-ranges converge in the south-east peninsula in a lofty chain which traverses the whole of Papua (formerly British New Guinea). The whole of the more central part of this system in Papua is generally known as the Owen Stanley Range, with Mount Victoria, its highest mountain, over 13,000 feet. Mount Albert Edward, the highest mountain in Papua, lies to the north of the 'Main' or Owen Stanley Range. The prevailing formations appear to be very old plutonic and sedimentary rocks. Gneiss and granites crop out in the Arfak highlands; elsewhere stratified clay-slates and old limestones abound; quartz and greenstones occur on the south-east coast resembling those of the auriferous region in New South Wales, and gold has been worked in several districts. Osmiridium has also been found, and petroleum has been located in both old and new British territories. Copper, now exported, occurs

in large quantities in the neighbourhood of Port Moresby, and a coalfield has been found on the Upper Kiko River. Earthquakes are frequent in some districts, such as the Bismarck Archipelago, and there are numbers of active volcanoes. Extinct craters are common throughout New Guinea.

A number of considerable rivers have been found in New Guinea. The three largest appear to be the Amberno (Mamberamo, or 'Great River') in Dutch, the Kaiserin Augusta, or Sepik, in new and the Fly in old British territory. The Amberno (the Rochussen of Dutch geographers) descends probably from the Nassau Mountains to the east side of Geelvink Bay, where it develops an extensive delta. The Sepik flows mostly from the central water-parting north-eastwards to the coast at Cape della Torre in 4° S. and 144° 30' E., entering the sea in a broad, deep channel without any delta. It is navigable for several hundred miles by vessels of small tonnage, and it has been explored as far as the Papuan border. But the largest of all New Guinea rivers is probably the Fly, which rises on the southern slope of the central water-parting and flows mainly south-east to a delta of vast extent on the west side of the Gulf of Papua. This great estuary, discovered in 1845 by Blackwood, was explored for over 600 miles by Sir William Macgregor. The tides ascend the Fly for 150 miles, and 90 miles higher up it is joined on its left bank by the Strickland. Feeding the lower reaches of the Strickland is a lake of some size, which has been named Lake Murray after the lieutenant-governor of Papua at the time of its discovery. North-eastwards, round the head of the gulf, are the deltas of three other great rivers—the Bamu, Turama, and Kiko, the last two flowing a long distance east-south-east, parallel to the Sir Arthur Gordon Range, before turning to the sea. Farther east comes the Purari, which runs by Mount Murray (8000 feet), and is navigable by steam-launch for 120 miles from its mouth. Among other navigable rivers on the south side of the main watershed are the Lakekamu, entering the gulf at Port Chalmers, the St Joseph, the Vanapa, and the Kemp Welch. On the north-east coast may be mentioned the Mambar, flowing at first north-west, the upper reaches being known as the Yodda; the Markham, which flows into the Huon Gulf; and the Ramu, which, after a course of over 400 miles, reaches the sea near the Sepik.

In 1908-9 Mackay and Little ascended the Purari River 100 miles farther than Macgregor had done. Captain Rawling's expedition (1909-11), in the Dutch territory, surveyed a large tract of country, and explored the Kapare and other rivers; while a Dutch expedition reached the snow-line of the central (Nassau) range. Staniforth Smith's expedition (1910-11), in the British territory, found that its western division—except along the coast and the navigable rivers—was a lofty plateau, and roughly defined the watersheds of the great rivers flowing into the Gulf of Papua. Subsequent patrols in Papua have opened up many new areas, and have penetrated to the former German boundary at several points.

The whole of New Guinea lies within the track of the south-east trade-winds, which prevail from March to October, and which are charged with much moisture from the Pacific. These are followed for the rest of the year by the north-west monsoons, whose rain-bearing clouds are condensed on the cold alpine slopes of the island. The consequence is that the rain or snow fall is considerable in every part of the country, and this, combined with an average high temperature of from 80° to 90° F., results in a hot, moist climate on all the low-lying coast-lands and fluvial valleys. Hence malaria is generally endemic in the low-

lands, and is sometimes conveyed to a considerable height above sea-level. But it has become rare at the chief settlements (Port Moresby, Samarai, &c.), where due precautions are taken against mosquitoes. In any case New Guinea, as a whole, seems unsuitable for permanent settlement by European races; but much of the soil is excellent for the cultivation of tropical produce by coloured labour (native or imported) under white direction. For instance, in Papua there are plantations of coconuts, sisal hemp, rubber, &c.; and 60,000 acres of land were under commercial cultivation in 1921 as compared with 1500 in 1907. Some of the uplands are suitable, if not for permanent colonisation, at least for the establishment of health-resorts for officials, traders, and missionaries.

Thanks to its abundant rainfall, varying altitudes, high temperature, and position intermediate between the Asiatic and Australian botanical areas, New Guinea is almost everywhere clothed with a rich and highly diversified flora. The vegetable zones appear to be even superimposed as in Mexico, and as Sir W. Macgregor states, after passing successively through the domains of tropical plants, such as the coconut, sago, banana, mango, taro, and sugar-cane, and of such temperate or sub-tropical growths as the cedar, oak, fig, acacia, pine, and tree-fern, he was gladdened on the higher slopes by the sight of the wild strawberry, forget-me-not, daisy, buttercup, and other familiar British plants. Towards the summits these were succeeded by a true alpine flora, in which Himalayan, Bornean (Kinabalu), New Zealand, and sub-antarctic forms were all numerous represented. In general, arboreal vegetation ceases at about 11,000 feet, and shrubs at 12,000, the latter being overlapped by the alpine zone. In New Guinea the Asiatic and Malayan floras are far more richly represented than the Australian, as shown by the rarity of the eucalyptus, a great number of varieties of which occur in the southern continent. Indigenous forms are numerous, and include many species of palm.

On the other hand, the New Guinea fauna is much more closely related to that of the Austral than to that of the northern hemisphere. This is seen in the almost total absence of placental mammals and the presence of over thirty species of marsupials, such as the cuscus and kangaroo, as well as the bower-bird, of which two new species were discovered on the Owen Stanley Range. Here also were found the European lark and blackbird in curious association with the bird of Paradise, of which typical New Guinea bird many species occur. Scarcely any birds of prey are found, a circumstance which may explain the presence of so many forms—parrots, cockatoos, pigeons, &c.—remarkable for their gorgeous plumage. Reptiles are numerous, and include a remarkable python (*Chondropython pulcher*), intermediate between the Asiatic python and American boa. A still more remarkable very primitive form is the spiny ant-eater, of which there are three species; it is allied to the Australian echidna, and like it oviparous. The placental mammals are represented only by some bats and mice, besides the pig and dingo, both probably introduced in early times.

Apparently man has invaded the island more than once, producing a population which differs markedly from that of Australia or Indonesia. Between the Australians and Papuans, who form the bulk of the New Guinea population, there is little in common except the dark colour. But the New Guinea natives are far from a homogeneous people. Three ethnical elements may be distinguished with some clearness: Papuans proper, diffused over the whole region; Negritoes, who

have been found in the more interior districts of Dutch and British territory; and Melanesians, who, mixed in various degrees with indigenous stocks, form over half of the population of former German territory, and, under the name of Papuo-Melanesians, occupy the south-east coastal regions of Papua. Malayan influence is also of importance in the north-west. The mingling of these elements in different proportions has brought about much diversity in the physical appearance, speech, usages, and general culture of the natives. The true Papuans of the Fly River are almost black, usually tall, with frizzled hair; but eastwards, among the Papuo-Melanesians, the stature decreases, colour becomes lighter, and the hair, though generally frizzly, is occasionally wavy. Native dwellings are frequently built on piles, not only in the shallow bays but also inland. Amongst Papuans communal houses are much used. The bow-and-arrow is the principal weapon, but this is replaced by the spear in the east. Cannibalism and head-hunting was prevalent in most districts until recently. The social organisation shows great variation throughout the territory. In some districts strict marital fidelity is customary, in others considerable laxity; government is by hereditary chiefs, or by secret societies, or, in some few cases, is almost anarchic. Though a few tribes are nomadic, most are agriculturists, and the domestic pig plays an important part in native economics. Many groups are industrious and keen traders, displaying remarkable skill, especially in the arts of pottery and wood-carving. In the island-groups lying off the south-east peninsula remarkable forms of trade and native money are characteristic.

New Guinea appears to have been first sighted by A. D'Abreu in 1511, and first visited by De Meneses about 1526, and Alvaro de Saavedra in 1528. It received its present name in 1546 from Ortiz de Retez (Roda), who was struck by the resemblance of its inhabitants to those of the Guinea coast in West Africa. During the flourishing period of the empire of Tidor the Malay sultans of that state extended their sway over the so-called *Raja Ampat* or 'Four Kingdoms' of Waiju, Salwatty, Mysol, and Waigamma, including large tracts on the adjacent mainland. In 1793 the East India Company occupied the island of Manassari in Geelvink Bay; but the British troops were soon withdrawn, and in 1814 the English government admitted the claims of Holland to the *Raja Ampat* as suzerain of the sultan of Tidor. In 1848 the Dutch proclaimed their sovereignty over the western half of the island, and in 1884 the remainder was divided between Great Britain and Germany. In 1920 the Dutch had in view the centralisation of the government in Manokwari, the territory having been previously administered from the residencies on the islands of Ternate and Amboina. In 1914 Rabaul, the capital of German New Guinea, was occupied by an Australian force. In 1921 the Australian military administration was replaced by a civil administration responsible to the Commonwealth of Australia, which holds a mandate under the League of Nations. Subjoined is a roughly estimated table of the areas and populations of the British and Dutch territories:

	Area in sq. miles.	Population.
Dutch New Guinea.....	150,000	200,000
Papua (British New Guinea)....	90,000	300,000
Territory of New Guinea (former German New Guinea)....	90,000	250,000
Total.....	330,000	750,000

In the Dutch section until recently the only settlement of resident officials was at Merauke,

in which district there has been some cultivation. Otherwise little has yet been done to develop the resources of the country. The southern half of the British territory, officially known as Papua, is administered from Port Moresby by a lieutenant-governor, appointed by the Commonwealth of Australia, with executive and legislative councils. An excellent native police force, in the charge of magistrates in fifteen stations, disposed throughout the territory, maintain order amongst the native population. A fair amount has been done to develop the resources of the country since its annexation. Copra, pearl-shell, gold, osmiridium, and copper are among the chief exports. The northern half of British territory, known as the 'Territory of New Guinea,' is administered from Rabaul, on the island of New Britain, by means of machinery modelled largely on that of Papua. Although the exploitation of the territory has been carried much farther than in the case of Papua, exploration has been neglected, nor is the region of government influence over the native population as extensive as in the case of Papua.

New Hampshire, the 'Granite State' and a New England state, is the most northerly of the thirteen original United States of North America, lying between 42° 40' and 45° 18' N. lat., and bounded N. by Quebec, E. by Maine and (for 18 miles) the Atlantic Ocean, S. by Massachusetts; on the W. the Connecticut River separates it from Vermont. Area, 9305 sq. m.—a fourth larger than Wales. The average elevation is about 1200 feet, the general slope being towards the south. The highest point is Mount Washington (6293 feet), in the White Mountains, which include more than a hundred peaks of note, mainly in the northernmost county; among the peaks over 5000 feet high are those bearing the names of the successive presidents, Adams, Jefferson, Madison, and Monroe. Geologically they consist of early metamorphic rocks; immense masses of granite and gneiss constitute the bare peaks that make the name of the range as appropriate in summer as in winter. The largest lake is Winnepiseogee (72 sq. m.); the principal rivers are the Connecticut, Merrimac, and Piscataqua. From Dover Point to its mouth the Piscataqua is about half a mile wide; and the volume and swiftness of its current at ebb-tide prevent the freezing of the water in Portsmouth harbour during the coldest winters. The Merrimac is said to turn more spindles and propel more shuttles than any other river in the world. The state is noted for its salubrious climate and grandly picturesque natural scenery. The mean annual temperature at Concord is 46° F.

The principal agricultural products are hay, potatoes, maize, and oats. There is much forest in the state. Agricultural interests steadily declined for a number of years, but New Hampshire has become very popular as a summer-resort, and the farmers, who owing to the rough and sterile soil could not compete in the great markets with

those of the West, now find a new and important market brought to their very doors. But manufacturing is the leading industry in New Hampshire, the chief centres being Manchester (the largest city), Nashua, and Dover. The chief mineral product is granite.

New Hampshire embraces ten counties, and returns two senators and two representatives to congress. The governor is elected biennially, and appoints the judiciary, who hold office to the age of seventy. The public schools are efficient. The principal college is Dartmouth, founded at Hanover in 1769. The capital is Concord.

History.—The earliest settlements were made in 1623 near Dover and Portsmouth. In 1641–79, 1689–92, and 1699–1741 New Hampshire was under the governor of Massachusetts, but during the intervening dates and until 1775 it was under royal governors of its own. The people took an active part in the revolution. A provisional government was formed in 1776, a state constitution adopted in 1784; and New Hampshire was the ninth state (21st June 1788) to ratify the national constitution. Pop. (1790) 141,885; (1840) 284,574; (1880) 346,991; (1900) 411,588; (1910) 430,572; (1920) 443,083.

New Hanover, an island of the Bismarck Archipelago; area, 570 sq. m. Its physical characteristics resemble those of New Britain (q.v.).

New Harmony, a village of Indiana, 28 miles by rail N.W. of Evansville, was first settled in 1815 by a German community of religious socialists, called Harmonists, under the leadership of George Rapp (q.v.). In 1824 the village and domain was purchased by Robert Owen for an experimental community on his system, but this failed after a test of nearly three years.

Newhaven, a seaport of Sussex, at the mouth of the Ouse, $8\frac{1}{2}$ miles E. of Brighton and 56 S. of London. It has risen into importance through its steamboat traffic, particularly to Dieppe (2 $\frac{1}{2}$ hours), and has a large fort (1864–69) and a little Norman 12th-century church, with an east tower and small semicircular apse, curiously like that of Yainville-sur-Seine. Pop. (1921) 6436.

Newhaven, a fishing-village, now within the burgh of Edinburgh. Dating from about 1490, it has a tidal harbour, and is famous for its fish dinners and fishwives.

New Haven, the chief city and seaport of Connecticut, and capital of New Haven county, at the head of New Haven Bay, 4 miles from Long Island Sound, and 73 miles by rail E.N.E. of New York. Its broad streets are shaded with elms, and the public squares, parks, and gardens, with its handsome public and private edifices, make it one of the most beautiful of American cities. It is the seat of Yale College (q.v.), the Sheffield Scientific School, the Peabody Museum, &c.; and also of the Hopkins grammar-school (1660). Its other public buildings include the former state-house, the city hall, and United States government building. The port has a large trade. But New Haven is of more consequence as a manufacturing town, employing many thousands of hands in its large works, and producing hardware, wire, clocks, cutlery, fire-arms, corsets, india-rubber goods, carriages, paper, musical instruments, &c. New Haven was settled in 1636 by a company from London, and the colony was not united to that of Connecticut until 1662; and till 1873 it was recognised as, jointly with Hartford, the capital of the state. It was incorporated as a town about 1665, and chartered as a city in 1784; and it retains a town as well as a city administration, choosing select-men, &c., besides a mayor, aldermen, and council. Pop. (1850) 22,529; (1900) 108,027; (1920) 162,537.

New Hebrides, a chain of islands in the Western Pacific, extending NNW. to SSE., and lying W. of Fiji and N.E. of New Caledonia. There are in all some thirty islands (area, 5500 sq. m.), of which twenty are inhabited, the people, mostly of the Melanesian race, numbering about 60,000. Some of the islands—e.g. Ambrym, Tanna, and Povei—have active volcanoes. The larger islands are Espiritu Santo (70 miles long by 40 wide), Mallicolo (56 miles by 20), Ambrym (22 miles by 17), Efate or Sandwich (30 miles by 15), Erromango (30 miles by 22), Tanna, Aneityum, Epi, Maiwo (Aurora), and Aragh (Pentecost). All are wooded, and some lofty, reaching 3000 feet. The climate is moist, but clear and healthy. This chain was discovered by the Portuguese navigator Quiros in 1606, and was thoroughly explored by Captain Cook in 1773. The chief exports are copra, maize, cocoa, cotton, and coffee, which go principally to Sydney and Nouméa (New Caledonia). The islands are under joint French and British administration.

New Holland. See AUSTRALIA.

New Holland, a port on the Humber opposite Hull, with which it is connected by steam ferry.

New Ireland, or NEU-MECKLENBURG, the largest island of the Bismarck Archipelago; area, 4900 sq. m.; length, 300 miles; width, 15 miles. The hills rise to 6500 feet, and they and the whole of the interior are richly wooded. The climate, products, and inhabitants resemble those of New Britain (q.v.).

New Jersey, a Middle Atlantic state and one of the thirteen original states of the Union, is bounded on the N. by New York; E. by Hudson River, Staten Island Sound, Raritan Bay, and the Atlantic; SW. by Delaware Bay; and W. by the Delaware River, which separates it from Pennsylvania. Its greatest length is 167 miles; its width varies from 32 to 59 miles. It has an area of 8224 sq. m.; it is the smallest of all the states save three, but it ranks just about midway amongst them in population.

In the north-west part of the state there are two portions of the Appalachian system. The Blue or Kittatinny Mountains extend along the Delaware from the Water Gap up, attaining a height of 1400 to 1800 feet. The highlands south and east of these consist of many ridges, their greatest height 1488 feet. In this part of the state are many small lakes. The Palisades, the Orange Mountains, and other hills are in the red sandstone region, which extends from the north-east to the central part of New Jersey. The Navesink highlands (282 feet), south of Sandy Hook, are the only considerable elevation on the Atlantic coast south of New England. The central portion of the state is generally level and fertile; the southern part is in large measure sandy, covered with pine-woods, and marshy near the coast. The state is abundantly watered; its chief rivers, the Passaic, Raritan, Little and Great Egg Harbor, flow south-east into bays. The coast from Sandy Hook to Cape May is generally protected by peninsula or island beaches; the only considerable exception to this rule being the strip of mainland, about 18 miles long, between Monmouth and Squan beaches.

In agriculture the state occupies a prominent position in proportion to its area. About 60 per cent. of the total land area is included in farms. While the average acreage of the farms decreased from 115·2 in 1850 to 76·8 in 1920, the number of farms largely increased. The chief products are maize, oats, wheat, rye, hay, potatoes and sweet potatoes, cattle, butter, milk, and market-garden produce. The leading mineral products are iron ore, limestone, zinc, potash, and slate. After oil-

refining, glass, pottery, machinery, leather, clay, cement, silk, and woollen and cotton goods are among the chief manufactures.

New Jersey returns two senators and twelve representatives to congress. The state legislature meets at the capital, Trenton, in January; a senator is chosen from each of the twenty-one counties (one-third each year) for three years; the assembly has about sixty members, who serve one year. There are (besides several county asylums) two large lunatic asylums near Trenton and Morristown, the latter accounted a model. Princeton (q.v.) University, founded in 1746, is the most famous institution in the state. There are many colleges and other institutions at or near Trenton (q.v.), at New Brunswick (q.v.), and at Hoboken (q.v.).

New Jersey has two canals, the Morris and the Raritan, and nearly 4000 miles of railroads. The position of the state, between the two great eastern cities and bordering upon both, has powerfully stimulated travel, industry, and population. Its south-west portion has Philadelphia for a market; its north-east section, including its two largest towns, is a suburb of New York. Its coast from Navesink to Squan is covered with villas, cottages, and hotels. Cape May, Long Branch, and Atlantic City are noted seaside resorts. Asbury Park, Ocean Grove, Seabright, &c., are growing places, crowded in summer. Newark and Jersey City are by far the largest cities; next come Paterson, Trenton, Camden, Elizabeth, Bayonne, Hoboken. Pop. (1800) 211,149; (1840) 373,306; (1880) 1,131,116; (1900) 1,883,669; (1910) 2,537,167; (1920) 3,155,900.

History.—In 1617 the Dutch settled at Bergen, near New York. In 1623 Cornelius May ascended the Delaware and built a fort 4 miles below the site of Camden. Some English colonists in that region were driven away in 1638 by the Swedes, who were conquered in 1655 by Peter Stuyvesant. In 1664 the territory was granted by Charles II. to the Duke of York, and by him to Lord John Berkeley and Sir George Carteret, with full power of government to them and their assignees. There was no trouble with the Indians, whose titles were peacefully purchased. The proprietors soon divided the territory into East and West Jersey. In 1674 Berkeley sold West Jersey to two Quakers, who settled Salem and Burlington; and in 1682 a society under Penn bought the Carteret rights in East Jersey. In 1702 the proprietors surrendered their power of government to the crown, and the two provinces were reunited; and from 1738 New Jersey had its own royal governors, always at issue with the assembly and the people. New Jersey bore its part in the colonial wars, contributed 10,726 men to the Continental army, besides militia, and spent over \$5,000,000 in the cause of liberty. It suffered heavily during the revolution, and was the scene of several important campaigns and battles. The state sent nearly 7000 men to the war of 1812, and for the civil war thirty-seven regiments of infantry, three of cavalry, and five batteries.

New Jersey Tea, a common name of Red Root (q.v.).

New Jerusalem Church. See SWEDEN-BORG.

New Lanark. See LANARK.

New London, a port of entry of Connecticut, is on the right bank of the river Thames, 3 miles from Long Island Sound, 51 by rail E. of New Haven, and 126 NNE. of New York, with which it has a daily steamboat communication. It has a court-house, a brown-stone city hall, and a granite custom-house. The manufactures include woollens,

sewing-silk, machinery, and hardware. The harbour is one of the best in the United States, and many vessels engaged in the coasting trade, and in sealing or fishing, are owned there. On the left bank of the river is a United States navy yard; and there are two forts, though no longer effective. New London was settled in 1645, and in 1781 was burned by Benedict Arnold. Pop. (1850) 8991; (1920) 25,688.

Newman, FRANCIS WILLIAM, brother of the Cardinal, was born in London in 1805, and educated at a private school at Ealing and at Worcester College, Oxford, where he obtained first-class honours in classics and mathematics in 1826, and, in the same year, a fellowship in Balliol College. This fellowship, however, he resigned; and he withdrew from the university in 1830, at the approach of the time for taking the degree of M.A., declining the subscription to the Thirty-nine Articles, which was required from candidates for the degree. After a three years' stay in the East, he was appointed classical tutor in Bristol College, 1834. In 1840 he accepted a similar professorship in Manchester New College, and in 1846 his reputation led to his being appointed to the chair of Latin in University College, London, which he held till 1869; meanwhile he was an active contributor to numerous literary and scientific periodicals, and to various branches of ancient and modern literature. In controversies on religion he took a part directly opposite to that chosen by his elder brother, being no less eager for a religion in his view more world-wide, and including whatever is best in the historical religions. *Phases of Faith* is by far the most widely diffused of his works, simply because it was mainly negative; but it was preceded by a book called *The Soul* (1849), which aimed to show a solid ground for divine aspirations in the human heart. He died at Weston-super-Mare on the 4th of October 1897. His works include four volumes of *Miscellanies* (1869–90); a *History of the Hebrew Monarchy* (1847); a *Dictionary of Modern Arabic*, in Romanised type (2 vols. 1871); a *Handbook of Modern Arabic* (1866), giving the dialect now used by literary men in all Arab-speaking regions; and a *Libyan Vocabulary* (1882), in which, cutting out the Arabic, he tried to reproduce the old Numidian, Mauretanian, and Gætulan. He also published mathematical volumes, including one on *Elliptic Integrals* (1889); and a small book on the earlier life of his brother, Cardinal Newman (1891). See I. G. Sieveking, *Memoir and Letters of F. W. Newman* (1909).

Newman, JOHN HENRY, CARDINAL (1801–90), the leader of the Oxford Tractarian movement of 1833 in the Church of England, who joined the Roman Catholic Church in 1845, and was made a cardinal by Leo XIII. in 1879. He was born in London on the 21st February 1801. His father was John Newman, a member of the banking firm of Ramsbottom, Newman, & Co. His mother was the child of an old Huguenot family which had settled in London as paper-manufacturers. She was a moderate Calvinist, and taught her children to love the school of Scott, Romaine, Newton, and Milner. Her children learned early to take great delight in the Bible, and Newman has always ascribed the utmost influence over his early religious views to his mother's teaching. From Scott, the commentator on the Bible, he learned two principles which may be traced in all his subsequent career. The first was to prize 'holiness before peace'; the second was that 'growth' is 'the only evidence of life.' From his reading of Law's *Serious Call* he dates his firm inward assent to the doctrine of eternal punishment, which he always held as taught by our

Lord himself; a doctrine, however, of which he often endeavoured to attenuate the mystery—notably in *Callista* (chap. xix.). Milner's *Church History* first attracted Newman to the writings of the early Fathers. Yet at the same time he derived from Newton's book on the prophecies a belief which more or less biased his mind long after he had ceased to accept it as a truth—that Rome is Antichrist. In the autumn of 1816 a belief took possession of him, as he tells us in his *Apologia*, that he was to lead a life of celibacy; and this belief held its ground, with certain brief intervals of 'a month now and a month then,' up to the age of twenty-eight, after which it remained absolutely fixed. Newman went to a private school at Ealing. The stoppage of his father's bank compelled him to take his degree at Oxford as early as possible without taking full time to read for honours, and he actually took it (from Trinity College) in 1820, when he was only nineteen, but overwork resulted in a partial failure. In 1821 he wrote jointly with a friend two cantos of a poem on St Bartholomew's Eve, but the fragment has never been republished. It should be added that Newman was always passionately fond of music, and showed delicacy and skill as a violinist.

In 1822 Newman was elected to a fellowship in Oriel College, then the most distinguished in the university; and it was here that, after a period of some loneliness, he formed his close intimacy with Dr Pusey, and subsequently with Hurrell Froude, whose dash and genius exerted a great influence over Newman, and who had a great share in starting the Tractarian movement of 1833. In 1823, too, Newman first read Butler's *Analogy*, from which he tells us that he learned to interpret the less certain aspects of natural religion in the sense of revealed religion, and especially to interpret natural phenomena in the sense of the sacramental system—i.e. as conveying mystical spiritual influences of which there is no external sign. Keble's *Christian Year* (1827) fell in exactly with this impression of the mystery at the heart of apparently purely physical influences. From Bishop Butler Newman also derived the principle that 'probability is the guide of life,' which, however, he more or less modified when he became a Roman Catholic, holding thenceforward that in all matters of first-rate religious importance certitude can be attained and not merely probability. At Oriel Newman formed cordial relations with Dr Hawkins, afterwards the provost of the college, and Whately, afterwards Archbishop of Dublin. Both of them exercised great influence over him by teaching him to define his thoughts clearly; and he afterwards expressed surprise that the casuistry of the Roman Church should have been credited with those habits of subtle discrimination which he had really gained from his Oxford colleagues.

Newman's first book, completed in 1832, but not published till 1833, was that on *The Arians of the Fourth Century*. It was a very careful and scholarly production, intended to show that the Arian heresy was not, as had been supposed, of Alexandrian origin, but was one of the Judaizing heresies which sprang up in Antioch. The book is a powerful vindication of the Athanasian doctrine of the divine nature of Jesus Christ from the imputation of being arbitrary, or in any way an unauthorised ecclesiastical addition to the essence of the Pauline and Johannine theology. Newman insists on the dogmatic definition of the Son as being 'of one substance' with the Father, and not merely 'of like substance,' as the only escape from either creature-worship on the one hand or the impossible assertion of the voluntary self-sacrifice of an eternal creator on man's account on the other.

In the late autumn of 1832 Newman accompanied Hurrell Froude and his father in a Mediterranean tour undertaken in the hope of restoring the health of the former. It was on this tour that the seed gradually germinated which was to bear fruit in the Anglican movement of 1833. Most of Newman's smaller poems were written on this voyage, and were soon afterwards published with the signature δ in the *Lyra Apostolica*, a volume of verse the object of which was to reassert for the Church of England her spiritual authority and mission with something of the ease and buoyancy of poetic license. It was on this tour that Newman first saw Monsignore (afterwards Cardinal) Wiseman in Rome, and told him gravely in reply to the expression of a courteous wish that Hurrell Froude and he might revisit Rome, 'We have a work to do in England.' At Rome Newman left his friends to go alone to Sicily, where he fell ill of malarial fever. His mind was deeply possessed during this illness by the idea of the work he had to do in England, and the delay in finding passage to England was very trying to him. He spent much of his time in the Roman Catholic churches, which he had up to this period refrained from visiting, and speaks with great feeling in one of his poems of the good offices of that church, though a 'foe,' in ministering to his sickness, like the good Samaritan to the wounded Jew. At last he got passage on an orange boat to Marseilles. Becalmed in the Straits of Bonifacio, he wrote the best known of all his poems, 'Lead, kindly Light.' From Marseilles he travelled straight to England, reaching home in time to be present at Keble's Oxford assize sermon on National Apostasy, which he always regarded as the date at which the Tractarian movement began. It was preached on July 14, 1833.

Into the series of *Tracts for the Times* which now commenced Newman threw himself with great energy; indeed he himself composed a considerable number of them. In the very first page of the first tract, which was his own, he told the bishops that 'black event though it would be for the country, yet we could not wish them a more blessed termination of their career than the spoiling of their goods and martyrdom.' The tracts which now began to pour forth were all intended to assert the authority of the Anglican Church, to claim apostolical descent for the Anglican episcopate, to advocate the restoration of a stricter discipline and the maintenance of a stricter orthodoxy, to insist on the primary importance of the sacraments, and the duty of loyalty to the church—Newman persuaded a friend to stay away from the marriage of a sister who had seceded from the Anglican Church—and in general to preserve the dogmatic purity of the church as well as to guard her divine ritual. But while he was full of confidence in these principles, which he held in common with Rome, what puzzled him was to justify adequately the strong anti-Romanist language of the greater Anglican divines; and a great part of his time was given during the Tractarian movement to laying down clearly the doctrine of the *via media* or midway course between popular Protestantism and Roman Catholicism, which he claimed that the Anglican divines of the 17th century had taken up. Up to nearly the end of his Anglican period he disapproved strongly the cultus of the Virgin Mary and the saints as interfering with the true worship of God. In 1837 he made an attempt to distinguish the Anglican *via media* from the doctrine of the Church of Rome in a course of lectures on 'The Prophetical Office of the Church viewed relatively to Romanism and Popular Protestantism.' In these lectures

he contrasted the attitude of the Anglican and Roman churches in reference to the use and abuse of private judgment, their attitude towards the principle of infallibility, their very different use of Scripture, and their view of the fortunes of the church. But while defending and defining as far as possible the *via media* of Anglicanism, Newman frankly admitted that it had never been practically enforced, and that it was a theoretic line on which no actual ecclesiastical policy had been founded. This it was which it remained for the Tractarians to do.

In 1838 Newman followed up his discussion of the *via media* so far as it affects authority with a volume on the *via media* in its relation to the doctrine of justification by faith. Again he taught that the Anglican Church takes a middle course between the Roman Catholic Church and popular Protestantism in maintaining that justification by faith—or the *imputation* without the *reality* of righteousness—must precede sanctification, which gives the reality, though sanctification must necessarily follow; while the Roman Catholic theology regarded sanctification as the whole substance of justification.

In Tract 85, which was also published in 1838, Newman made an effort to apply the theology of the *via media* to the interpretation of Scripture. He held that the Roman Catholic Church takes a view too independent of Scripture, while the Anglican Church is right in asserting that all revealed doctrine is to be found in Scripture, though it could not be found on the mere *surface* of Scripture, since it needs the guidance of the church's traditions to help us to find it there. He admitted most fully that the stress which one might expect to be laid is not laid in Scripture on baptism, on confession, on absolution, nor even on public worship itself, and that we can only find these doctrines in Scripture by attaching the importance which tradition teaches us to attach to the hints and *obiter dicta* of Scripture. Scripture, he held, *verifies* the teaching of the church rather than systematically inculcates it. Tract 85 was one of the most careful and characteristic of all Newman's essays as a Tractarian.

Tract 90, which appeared early in 1841, and which gave rise to so much agitation in Oxford, was the most famous, but certainly one of the least interesting of the tracts. The right wing of the Tractarian party, headed by William George Ward (q.v.), was at this time urging Newman to reconcile his High Church doctrines with the Thirty-nine Articles. This Newman thought a comparatively easy matter. The Articles recognise the teaching of the Books of Homilies as 'godly and wholesome;' and Newman contended that there was therefore ample evidence that the intention of the Articles was Catholic in spirit, and that they were aimed at the supremacy of the pope and the popular abuses of the Catholic Church in practice, and not at Catholic doctrine. The Homilies regard the first seven hundred years of the Catholic Church as quite pure, recognise six councils as received by all Christians, and speak of many of the Fathers as inspired by the Holy Ghost. Clearly therefore, in Newman's opinion, they were meant to gain over the moderate Romanists; and clearly they were not directed against the Council of Trent, for when the Articles were promulgated the council was not over. But in spite of this really substantial defence for the Anglican view of the Articles, Tract 90 provoked an explosion which was the end of the Tractarian movement, and brought on the conversion to Rome of those of the Tractarians who were most logical as well as most in earnest. The tract was repudiated by those in authority; the bishops almost all declared against

the movement; Newman struggled for two years longer to think his position tenable, but in 1843 resigned the vicarage of St Mary's, which he had held since 1828, and retired to Littlemore (q.v.). The magnificent university sermon on 'Development in Christian Doctrine,' which was the preliminary stage of his *Essay on Development*, was the last which he preached in the university pulpit—viz. on the 2d February 1843. During his life at Littlemore he was a man suspected of all sorts of disloyalty to his church—for example, of being a Roman Catholic already, who only concealed his change of faith in order to exert more influence over other Anglicans—a course of which he was quite incapable. On the 8th October 1845 he invited the Passionist Father Dominic to his house at Littlemore in order that he might be received into the Roman Catholic Church, and on the following day he was received; and within a few months he had left Oxford, which he never saw again for thirty years.

Of Newman's life as a Roman Catholic it is necessary to speak only briefly. It was, however, in a literary point of view much more free and natural than his somewhat repressed and severely reined-in life as an Anglican. He first went to Oscott to be confirmed; then he went to Rome for a year and a half; and on his return in 1848 he published *Loss and Gain*, the story of an Oxford conversion very different from his own, but full of happy and delicate sketches of Oxford life and manners. Shortly afterwards he began, but did not at that time conclude, *Callista*, the story of a martyr in Africa of the 3d century. The little book is full of literary genius as well as of religious devotion, and it contains a most vivid picture of the devastation worked by the locusts in that country, as well as a still more impressive picture of Newman's conception of the phenomenon of demoniacal possession. In 1848 Newman established a branch of the brotherhood of St Philip Neri (q.v.) in England (see ORATORY). Newman established himself at Edgbaston, a suburb of Birmingham; and here he did a great deal of hard work, devoting himself to the sufferers from cholera in 1849 with the utmost zeal. The lectures on *Anglican Difficulties*, intended to show that Tractarian principles could only issue in submission to Rome on the part of any Tractarian who had a logical perception of what the movement meant, was the first book which drew public attention to Newman's great power of irony and the singular delicacy of his literary style. These lectures were delivered and published in 1850, and were followed in 1851 by the Lectures on 'Catholicism in England,' in which the Protestant prejudices and prepossessions about Roman Catholics were painted with a great power of ridicule and even caricature. This was the book which gave occasion to Dr Achilli's action for libel against Newman, tried by Lord Campbell, in which the verdict went against Dr Newman so far as this, that the jury thought that he had not succeeded in justifying the libel, and awarded damages of £100 against him, while the costs of the case are said to have amounted to £10,000. Lord Campbell's charge was deemed very one-sided even by Protestants.

Newman will probably be longer remembered as a great preacher than in any other capacity. His long series of Oxford sermons contain some of the finest ever preached from an Anglican pulpit, and his Roman Catholic volumes—*Sermons addressed to Mixed Congregations* (1849) and *Sermons on Various Occasions* (1857)—though less remarkable for their pathos, are even fuller of fine rhetoric, and show the rarest finish. In 1864 a casual remark by Canon Kingsley in *Macmillan's Magazine* on the indifference of the Roman Church to the virtue of truth-

fulness, an indifference which he asserted that Dr Newman approved, led to a correspondence which resulted in the publication of the remarkable *Apologetica pro Vita Sua*, afterwards slightly recast as *A History of My Religious Opinions*. In this book Dr Newman gave us much the most fresh and effective religious autobiography of the 19th century, and completely vindicated the simplicity and candour of his own theological career. It is perhaps the most fascinating of his many works, as it is of course the most personal. In 1865 Newman wrote a poem of singular beauty, giving his view of a good Roman Catholic's experience in death, called *The Dream of Gerontius*. It is a poem of marvellous subtlety and pathos, as unique in treatment as it is in subject, and is now republished in the volume of *Verses on Various Occasions* (1874), which contains also all the pieces originally published in the *Lyra Apostolica*. In 1870 he published his *Grammar of Assent*, a book on the philosophy of faith, based on the view that a believing and even credulous attitude of mind clears itself much more easily of false beliefs than a sceptical attitude of mind clears itself of false denials. In the controversies which led to the Vatican Council Newman sided with the Inopportunist. He believed that the decree of the pope's personal infallibility in putting forth *ex cathedra* definitions on theology or morals intended to teach the church would alienate many Anglicans from the Roman Church, and he thought the doctrine, though true, not ripe for definition, nor pressed upon the attention of the church by any heresy. He was at this time in vehement opposition to the Ultramontanes under Archbishop Manning and William George Ward, and the bitterness between the two parties ran very high. Under Leo XIII. the policy of the church altered, and the new pope was anxious to show his sympathy with the English Catholic moderates; and in 1879 Newman was summoned to Rome to receive the cardinal's hat. In acknowledging congratulations he renewed his protest against liberalism in religion, the depreciation of revealed dogma, and the popular view that one creed, honestly held and practised, is as good as another. In the last eleven years of his life his most notable publication was an essay in attenuation of the difficulty of treating Scripture as plenary inspired, suggesting that inspiration does not necessarily include mere matters of detail in history, unless these are of the nature of what are called 'dogmatic facts'—facts which lie at the basis of revealed truths, such as the supernatural birth of Christ. He died of pneumonia on the 11th August 1890, after a very short illness.

Newman has of late become a recognised spiritual power in France, where many devout and distinguished Catholics have pronounced him the greatest theologian of his time. The modernists claim him as a spiritual father, mainly in virtue of his theory of development; and wide as are their differences in dogmatic detail, Loisy professes discipleship, with obvious grounds of justification. See works by Loisy, Thureau-Dangin, Dimnet, Lucie Félix Faure, Grappe, Raoul Gout, and the Abbé Brémond (1905-12); and on Newman's life generally, the standard Life by Wilfrid Ward (1912); his own letters, edited by Miss Mozley (1891); and works on him by R. H. Hutton (writer of the above article), Waller and Burrow (1901), Whyte (1903), Barry (1904), Sarolea (1908), Bertram Newman (1925).

Newmarket, the 'racing capital of England,' lies in Suffolk on the border of Cambridgeshire, 14 miles ENE. of Cambridge and 69 NNE. of London. Twice almost destroyed by fire, in 1683 and 1700, it chiefly consists of one long street, and contains an unusual number of hotels and fine private houses, belonging to the great patrons of the turf. Principal edifices are the Jockey Club (1773); the adjoining Subscription Rooms (1844);

the King Edward Memorial Hall (1913); the Rous Memorial Hospital (1883), with almshouses for eight jockeys and trainers or their widows; St Mary's Church, Perpendicular in style; and All Saints (1877). The town owes its prosperity to its horseraces, as old at least as 1605; and nearly half the male population are jockeys, trainers, or stablemen (Holcroft the dramatist was once one of their number). The race-ground, on Newmarket Heath, to the west, which is traversed by the Devil's Dyke (see CAMBRIDGESHIRE), is owned by the Jockey Club, and, with its soft elastic turf, is one of the very finest in the world. Of its ten courses, the longest is $4\frac{1}{2}$ miles in circuit. The training-ground bears a like character for excellence, and 400 horses are constantly in training. There are eight annual meetings, the principal events being the Two Thousand at Easter and the Cambridgeshire and Cesarewitch in October. Pop. (1851) 3356; (1921) 9752. See HORSERACING.

New Mexico, a south-western state of the United States, admitted in 1911, an earlier scheme for incorporating it with Arizona as a new state having been defeated (1905) by the opposition of Arizona. Bounded N. by Colorado, E. by Oklahoma and Texas, W. by Arizona, and S. by Texas and Mexico, it has an area of 122,580 square miles, and exceeds in size all the states of the union except Texas, California, and Montana. The population in 1880 was 119,565, and in 1920 360,350. The surface of the region belongs to the great plateau upon which rests the Rocky Mountain system. From an altitude of 6000 to 6500 feet in the north it descends gradually to about 4000 feet along the Mexican border, and sinks to 3000 or 3500 in the Llano Estacado of the south-east. Except in the east the whole region is traversed by broken ranges of mountains having in general a north and south trend. In the northern central part the Santa Fé, Las Vegas, and Taos ranges form part of the main axis of the Rocky Mountains, with a number of peaks over 12,000 feet high. Farther south, and east of the Rio Grande, are numerous broken ranges; and west of the Rio Grande the Sierra Madre rise above the level of the *mesa* (plateau) in various ranges. These mountains and the intervening *mesas* are cut by deep cañons. In the north-west a number of chains cross the Arizona boundary, and the San Juan Mountains enter the territory from Colorado. Among the mountains, especially in the north-east, are many 'parks' noted for their beauty and fertile soils. The surface rocks belong mainly to the Cretaceous period, with belts of Triassic formation. The mountain-chains and great part of the Sierra Madre plateau are much older. There are many tracts of metamorphic rock and lava overflows, some of which appear to be of comparatively recent date.

The precious metals are found in almost all parts of the state. Some of the most important mines are in the south-west near Silver City, Deming, and Lordsburg, others in the central region in the vicinity of Socorro, and farther north near Santa Fé. There are also valuable mines in San Juan county. Some of these mines were rudely worked by the early Spaniards, who compelled the Pueblos to labour like slaves. In several places old shafts have been discovered which were filled in by the Indians when they successfully revolted from this tyranny. Iron, lead, and copper occur in valuable deposits, and near Santa Fé are famous turquoise mines. There are also fields of both bituminous and anthracite coal. Mineral and hot springs are numerous.

The great mountain-divide causes the drainage of the region to flow south to the Gulf of Mexico, and west to the Pacific Ocean. The Rio Grande

traverses the central part of the state and receives many tributaries. The Rio Pecos which joins it in Texas drains the south-eastern part. In the north-east are streams which unite to form the Canadian River, and in the west are the headwaters of the San Juan, Little Colorado, and Gila, all affluents of the Colorado. In the river-valleys the soil is fertile and produces excellent crops; and many acres elsewhere may be (and are) successfully cultivated by irrigation. Specially notable is the vast Elephant Butte reservoir on the Rio Grande, 45 miles long, completed in 1916. The climate is healthful, and on the whole remarkably uniform, and the atmosphere is very pure and dry. The death-rate from pulmonary diseases is the lowest in the country. The rainy season occurs between the middle of July and the middle of September, lasting about a month. There are extensive forests on the mountains, and in the hilly regions of the western part of the state, and on the pastoral plains nutritious grasses which support great numbers of cattle and sheep. The yucca and cactus are characteristic forms of vegetation, especially in the Llano Estacado. Stock-raising is one of the leading industries. The flocks and herds need no housing in the winter, but of late years more attention has been given to improvement of the breeds, and the stock, instead of roaming at will, is often confined within enclosed ranges.

Though one of the most recently settled portions of the Union, New Mexico was among the earliest regions occupied by the white man, and Santa Fé, originally an Indian pueblo, claims the title of the oldest town in the country. When the Spaniards first visited this region they found a people living in communities with substantial dwellings, and marking the decay of a civilisation which had flourished in previous centuries. Excavation is yielding good results. In 1822 the people of New Mexico, in common with the other inhabitants of Mexico, of which it then formed a part, threw off the Spanish yoke. By the treaty of Guadalupe Hidalgo in 1848, after the war between Mexico and the United States, part of the territory was acquired by the latter nation. Additions were made by a later purchase from Mexico and by a cession from Texas. The population still includes about 20,000 'Mexicans,' and 20,000 Indians (see APACHES, NAVAJO, PUEBLOS). Santa Fé (q.v.) is the capital of the state; the state university is at Albuquerque.

Newnes, SIR GEORGE (1857-1910), son of a Matlock Congregational minister, founded *Tit-Bits* (1881), *The Strand Magazine* (1891), and other periodicals, sat as a Liberal for Newmarket (1885-95) and Swansea (1900-10), and was made a baronet in 1895. See PERIODICALS.

Newnham College, Cambridge, dates from 1871, when the Newnham Hall Company opened a house for five resident women students; Professor Sidgwick (q.v.) being from the first one of the most helpful friends of the enterprise. The numbers steadily increased, and in 1875 Newnham Hall was built, providing rooms for the principal, a lecturer, and twenty-six students. Scholarships were given by the London Companies and private friends, the library grew, a chemical laboratory and gymnasium were added, and the whole machinery of the college became more and more complete till, in 1879, the Newnham Hall Company was amalgamated with the Association for the Promotion of the Higher Education of Women. Additional land was acquired, and halls added. Old Hall, Sidgwick Hall, Clough Hall, and Peile Hall (1910), with the Pfeiffer Building (1893), Kennedy Buildings (1906), and a library, now form Newnham College. In 1881 the university

of Cambridge opened to students of Newnham and Girton some of its examinations, but not till 1921 its degrees. Trinity College, Dublin, however, admitted them meanwhile to *ad eundem* degrees. Miss Anne Clough (1820-92), sister of the poet, the first principal of the college, was succeeded by Mrs Sidgwick (see SIDGWICK, HENRY), Miss Stephen, Miss B. A. Clough, and Mrs J. P. Strachey (from 1924).

New Orleans, chief city of Louisiana and one of the greatest commercial cities in the Union, is situated on both sides of the Mississippi River—mostly on the east bank—107 miles from its mouth. The corporate area is 265 sq. m., but a large portion of this is market-gardens, forest, and swamp. The Mississippi makes two bends here, giving the old city a crescent-shaped front, whence its former title, 'The Crescent City,' but it has now the shape of the letter S. The river is from 600 to 1000 yards wide, and 60 to 240 feet deep. The bar at its mouth was removed in 1874-79 by the Eads jetties in South Pass, and vessels of 30 feet now easily reach New Orleans. On the north the city fronts Lake Pontchartrain, which connects directly with the Gulf by two channels, by one of which it is proposed to open communication for ships of 40 or 45 feet between city and sea. In 1923 the Industrial Canal was completed, which runs through the city from the lake to the Mississippi (over 5 miles). The commerce of the city is large, especially in cotton, for it is one of the world's greatest cotton markets, and has a great trade in fish, oysters, and other commodities. Since 1875 it has made great progress in manufactures, particularly in cotton goods, cotton-seed oil, shoes, machinery, lumber, furniture, fertilisers, sugar, rice-milling, cigars, &c.

The land upon which New Orleans is built is perfectly flat, and lies from 3 to 6 feet below the level of the Mississippi at high-water, and is protected from overflow by levees or dykes of earth. Similar levees in the rear keep out the waters of Lake Pontchartrain. The soil is saturated with water, and cellars are impossible. The climate is warm and damp, the mean temperature for the year being 69° F. The summer is tempered by winds from the Gulf, and is not oppressively warm. On account of its situation, the city is badly drained. Its health, however, has greatly improved.

While it possesses few imposing buildings, New Orleans is a picturesque city. There are several parks little improved, but with handsome monuments or statues of Jackson, Lee, Franklin, and others. The custom-house of granite is the largest and most imposing building in the city. The cathedral of St Louis, a Gothic church erected in 1794, is a good sample of the Creole-Spanish architecture. The archiepiscopal palace (1737) is the oldest building in the city. Other noteworthy structures are the cotton exchange, United States branch mint, and Christ and St Patrick's churches. Tulane University (known as the University of Louisiana from 1834 to 1883) is the principal educational institution. The Sophie Newcomb Memorial College (1887) is for the higher education of girls. Loyola University is Roman Catholic. There are colleges for negroes. The Howard Memorial (1888), Tulane, and Louisiana State libraries are all free. The Charity Hospital (1784) is the largest of many.

The site of New Orleans was first visited in 1699 by Bienville, who in 1718 laid the foundations of the city, and in 1726 made it the capital. In 1763 it was ceded to Spain by France, with the rest of Louisiana; but when in 1765 the Spanish governor, Ulloa, attempted to take possession, he was driven out, and the people established a government of their own. In 1769 New Orleans was occupied by the Spanish, and the leaders in the

late movement were shot. It was ceded to France in 1802, and transferred to the United States a few days later. Incorporated as a city in 1804, it was divided in 1836 into three separate municipalities, in consequence of the jealousies between the Creoles and the Americans; but the three were again consolidated into one in 1852. Since then New Orleans has annexed the neighbouring towns of Lafayette, Jefferson, Carrollton, and Algiers. Other outstanding events in the history of the city have been the battle of New Orleans (see JACKSON) in 1815; its capture in 1862 by the Federal fleet under Admiral Farragut (q.v.); serious political troubles in 1874 and 1877, resulting in 1874 in a battle on the levee between the citizens and the police and militia, in which 46 persons were killed and 216 wounded; and the lynching in 1891 of 11 Italian *maffiosi*. In 1880 the capital of Louisiana was removed from New Orleans to Baton Rouge.

Pop. (1769, when it was transferred to Spain) 3190; (1802, when it became American) 10,508; (1840) 102,193; (1880) 216,190; (1900) 287,104; (1910) 339,075; (1920) 387,219. The city is very cosmopolitan in race and language. Italians and Germans prevail among the foreign-born. There are over 100,000 negroes.

New Plymouth, the chief town of the provincial district of Taranaki, New Zealand, 220 miles NW. of Wellington by rail. Two miles from the town is an extensive roadstead. Pop. 13,000.

Newport, since 1891 a county borough of Monmouthshire, and a parliamentary borough (till 1918 combining with Monmouth and Usk), is seated on the river Usk, about 4 miles from its junction with the Severn, 24 miles SSW. of Monmouth and 145 W. of London, and it is one of the principal outlets for the produce of the extensive collieries and iron and steel works in the vicinity. Its shipping trade has greatly increased, and with it its dock accommodation, which now covers more than 100 acres (the Alexandra South Dock being the biggest in England). Newport is the largest iron-exporting port in the kingdom, and ranks third amongst the coal-exporting ports. Iron pyrites and manganese are imported. The town has many fine public buildings, prominent amongst them being the town-hall (1885) and St Woollos' Church, occupying an elevated site, and in style partly Norman and partly Perpendicular. On the creation of the Welsh diocese of Monmouth St Woollos' became its pro-cathedral. A transporter bridge (1903) crosses the river about 1½ mile below the road bridge which carries the traffic between London and South Wales. Besides its shipping trade, Newport has manufactures of india-rubber, gutta-percha, and railway and telegraph plant and wagons, whilst several important brass and iron foundries are in operation, as well as breweries and pottery-works. On 4th November 1839 the town was the centre of a Chartist outbreak, which resulted in the death of twenty persons, and the wounding of many more. Pop. (1801) 1087; (1891) 54,707; (1921) 93,700.

Newport, an urban district of Shropshire, on the Shrewsbury Canal, 11 miles WSW. of Stafford. Chartered by Henry I., and burned in 1665, it has a 15th-century church, a grammar-school (1656), and manufactures of machinery. Pop. 3000.

Newport, the capital of the Isle of Wight, on the navigable Medina, near the centre of the island, 4½ miles S. of Cowes and 10 SW. of Ryde. The church, rebuilt in 1854-56 on the site of one nearly 700 years old, is a fine Decorated edifice, and contains Marochetti's beautiful monument, erected by Queen Victoria in memory of the Princess Elizabeth, who died at Carisbrooke Castle (q.v.) on 8th September 1650. Newport besides has a

town-hall (1810); a free grammar-school (1612), the scene in 1648 of the protracted but fruitless negotiations between the parliamentary commissioners and Charles I., to whose secret 'engagement' a year before with the Presbyterian Scots the town also gave name; a diocesan school (1860); and a literary institute and museum. To the north-west are a reformatory (1838) and barracks (1798). A municipal borough, Newport returned two members till 1867, and then one till 1885. Pop. 11,000.

Newport, a town of Fife, on the Firth of Tay, 1½ mile by water SSE. of Dundee, has a small harbour designed by Telford (1822), and municipal buildings (1890). Pop. 3300.

Newport, (1) a city of Kentucky, is on the Ohio, opposite Cincinnati, and at the mouth of the Licking River, which separates it from Covington; both rivers are bridged. The city contains large rolling-mills and steel-works. Pop. (1880) 15,693; (1920) 29,317.—(2) A port and till 1900 one of the capitals of Rhode Island, on the west shore of the island of Rhode Island, in Narragansett Bay, 5 miles from the ocean, and 69 miles by rail S. by W. of Boston. It has a deep, excellent harbour, defended by Fort Adams. It is noted for fine scenery and sea-bathing, and is one of the most fashionable watering-places in America. In Touro Park stands the 'Round Tower,' or 'Old Stone Mill,' which suggested Longfellow's poem 'The Skeleton in Armour.' It was settled in 1638 by eighteen adherents of Roger Williams, and was an important commercial town prior to the Revolution, which effected its ruin and transferred its trade to New York. Newport was for a time the residence of Bishop Berkeley. Pop. (1880) 15,693; (1900) 22,034; (1920) 30,255.

Newport News, a city and port of Virginia, on the north shore of the estuary of the James River, has extensive shipbuilding yards, iron-works, &c.; pop. 35,600.

Newport-Pagnell, an urban district of Bucks, at the influx of the Ousel to the Ouse, 56 miles NNW. of London. Named from the Paganels, who owned the manor in the days of Rufus, it was taken by Essex in 1643, and held two years later by Sir Samuel Luke, the prototype of Butler's 'Hudibras.' The fine parish church, restored by Street in 1858, is the principal edifice; lace-making has declined. Pop. 4000.

New Red Sandstone. See PERMIAN SYSTEM, TRIASSIC SYSTEM.

New River, an artificial cut, running 38 miles southward from Chadwell Springs in Hertfordshire into reservoirs at Hornsey and Stoke Newington. It was designed for the water-supply of London, and completed (1609-20) at a cost of £500,000 by Sir Hugh Myddelton, goldsmith, who died poor on 10th December 1631. In 1904 the company was taken over by the newly formed Metropolitan Water Board.

New Rochelle, a city of New York, in Westchester county, on Long Island Sound, is a residential suburb of New York; pop. 36,000.

New Ross, a river-port of Wexford, on the Barrow (till 1898 partly in Kilkenny County), 15 miles NE. of Waterford. Old Ross lies 5 miles to the east. Before the Union New Ross returned two members to parliament, and down to 1885 one. It was founded by Strongbow's daughter, and was formerly fortified. Pop. 5500.

Newry, a seaport, till 1918 a parliamentary borough, in County Down, on the Newry River, 38 miles SSW. of Belfast by rail. A canal connects it with Carlingford Lough and with Lough Neagh. The town is handsomely and compactly built, and the port does a large trade with Glasgow

and Liverpool in cattle and other agricultural produce. Flax spinning and weaving, with rope and sail making, tanning, and granite-polishing, are the industries. The place dates from 1131; its castle was taken by Edward Bruce in 1318. Pop. 12,000.

New Shoreham. See SHOREHAM.

New Siberia, a group of uninhabited islands in the Arctic Ocean, lying off the coast of Siberia, between the mouth of the Lena and the mouth of the Indigirka. The principal are Kotelnoi (the largest), Liakhov, Fadeyeff, and New Siberia. The soil contains immense quantities of mammoth and other fossil ivory.

New South Wales, one of the States of the Australian Commonwealth, is the oldest and most populous colony in Australia. The name was given by Captain Cook (at first in the form 'New Wales') to the coast-line which he discovered in 1770, apparently because he saw some resemblance between it and that of Wales; it was therefore applied to the first British colony founded in Australia, which extended nominally from that coast to long. 135° E. As other settlements were made, this area was gradually limited to that of the present state.

The boundaries of New South Wales are: on the north the 29th parallel of south latitude, with two northward bulges near the coast, reaching the Pacific at Point Danger, and separating the state from that of Queensland; on the east, the Pacific Ocean—here known as the Tasman Sea; on the south, a line from Cape Howe to the source of the Murray, and the left bank of that river, separating New South Wales from Victoria; on the west, the 141st parallel of east longitude, separating it from South Australia. The enclosed area is 310,372 sq. m., a tenth part of Australia, but nearly three times as large as Great Britain and Ireland. For the history of the colony, see AUSTRALIA.

Geography.—New South Wales is made up of two series of plains, the coastal and the western, separated by a tableland, which towards the centre of the State has been worn away to a mere watershed. Along this tableland run north and south a series of low ridges with a few peaks, to which different names are given at different points; but the words 'range' and 'mount' must be understood to refer to these plateaux and humps, not to the features which they connote in European usage. Thus Mount Kosciusko, the highest hill in Australia (7328 feet) and the summit of the Australian Alps, is merely one of many hummocks on a plateau well over 6000 feet high. As it extends northwards, the tableland drops to about 3000 to 4000 feet, and ends a little to the north-west of Sydney, where the softer rocks of the great coal-basin have been worn away by the Goulburn River and its tributaries on one side, and the Namoi and its tributaries on the other, of the volcanically formed Liverpool Range. On the northern side of the Namoi valley begins another tableland, the New England Range, whose higher levels reach 4000 feet, while the highest point, Ben Lomond, is another hummock only 500 feet above the railway-line which traverses the tableland. The rivers of both tablelands flow usually northwards at first, then turning east or west to the sea or the plains; in New England they fall suddenly over great cliffs into deep cañons as they turn—farther south they cut huge gorges for themselves before turning seawards; in both cases the westerly-flowing streams descend to the plains by easier grades. The Clarence (190 miles long, draining about 8000 sq. m.) and Macleay (160 miles) are examples of the first kind; the Hawkesbury (335 miles, draining about 8000 sq. m.) and Shoalhaven (220

miles) of the second. The Hunter (340 miles), with its tributary the Goulburn, drains the low land between the tablelands. The western rivers, of which the chief are the Murrumbidgee (1050 miles), Lachlan (850), Macquarie (590), Castlereagh (340), Namoi (430), Gwydir (350), and Macintyre (180), on emerging from the foothills of the tablelands drift slowly to the Murray or its great affluent the Darling; but the bulk of the water they receive from the hills either evaporates in the summer heat of the plain country or sinks through porous soil, mostly replenishing the reservoirs from which artesian wells derive their supply. The Murray itself has 1200 miles of its course in the State, out of a total of 1600; the Darling has 1760 to its junction with the Murray. The lengths given above for the other western rivers are measured to their junctions with the Murray or Darling. There are few real lakes: those on the coast (e.g. Lakes Macquarie and Illawarra) are lagoons connected with the sea; those of the inland plain (e.g. Menindie, Cawndilla, and Victoria) are depressions occasionally filled with flood-water from the Darling; Lake George is a portion of the Murrumbidgee basin isolated by earthquake action, and is often dry for years together; the real lakes of the Kosciusko plateau are of small area. The coast-line is unusually uniform in trend, running from NNE. to SSW. in almost strict parallelism with the great tablelands; the deep and ramifying inlets of the coast just north and south of Sydney are replicas of the deep gorges forty miles inland. Port Jackson, indeed, is a typical Blue Mountain valley. Farther north and south there are few harbours that do not require constant dredging; most of them are river-mouths blocked by bars of their own silt, which a steady north and south ocean current will not allow to be thrust farther seawards—hence the few deltas do not extend beyond the protection of neighbouring headlands. Port Stephens, to the north of the Hunter estuary, and Jervis Bay, south of the Shoalhaven, are the only natural harbours beyond the central (Sydney) area. The principal towns are Sydney (q.v.); Parramatta, just inland from it; Newcastle, Maitland, and Cessnock, in the Hunter valley; Goulburn, on the southern tableland; Lithgow (the future federal arsenal), in the hills between Bathurst and Sydney; and Broken Hill, in the extreme west. Towns with less than 10,000 population, but still worth noting, are Albury, on the Murray; Wagga and Hay, on the Murrumbidgee; Bathurst, on the Upper Macquarie; Armidale on, and Tamworth at the foot of, the New England tableland; and Grafton and Lismore, in the northern coastal valleys.

Geology.—'Physiographically,' says Professor David, 'New South Wales consists of immense tablelands and plains of ancient hard rocks, often highly crystalline, ranging from Archæan to Carboniferous in geological age, and containing lodes and reefs of gold, silver, copper, lead, zinc, tin, antimony, bismuth, molybdenite, tungsten, &c.' A deep hollow in this substructure holds the great central coal-basin, whose centre lies 3000 feet below Sydney, and whose edges, roughly speaking, are lines drawn from Gunnedah, on the Namoi, to Port Stephens and Jervis Bay. A second coalfield of Trias-Jura age occurs in the north-east of the State, and Trias-Jura sandstones underlie the whole of the artesian basin which spreads across the northern plains, bounded on the south by the Macquarie and the Darling as far as Louth. The tablelands are Palæozoic, diversified with volcanic upbreaks, especially in the New England district. Of the western plains two great areas, one stretching from Cobar towards the Darling and Lachlan, the other round Mount Brown and the Barrier

Ranges in the far west, are also Palaeozoic; a third along the Murray and lower Darling is a depression filled with the sediments of an Eocene sea; a fourth is the artesian (Trias-Jura capped with Cretaceous sediments) basin just spoken of. All these are covered for the most part by red and black soils (the latter the mark of ancient river-beds) formed from the disintegration of Desert Sandstone (Upper Cretaceous) deposits. The oldest sedimentary rocks occur in the Barrier Ranges, wherein no fossils have yet been found. A remarkable feature of the State's geology is the occurrence at many points in the southern tableland of oval limestone areas, containing fossil corals and marine shells similar to those now found in the Barrier Reef of Queensland (q.v.). Seventeen of these areas are known, and in most there are caves of the Cheddar type, though much larger. In a series near Wellington the bones of extinct marsupials of great size—e.g. the *Diprotodon*, a wombat 16 feet long—are found under a thin layer of stalagmite.

Industries.—Almost the first, and always the chief, industry of the State has been wool-growing. Its stations in normal years contain over 40 per cent. of the sheep of the Commonwealth, and yield about 47 per cent. of the wool; its horses number nearly a third, and its cattle about a quarter, of the Australian totals. (The best New South Wales cattle, by-the-by, are in its dairy herds; it is the dry inlands of the far north that rear the Commonwealth's finest beef-producing cattle.) The mining industry is next in importance. Coal, which was first discovered at Newcastle and Coal-cliff (near Bulli) almost simultaneously in 1797, is obtained mainly in three districts—Maitland-Cessnock, in the lower Hunter valley; Lithgow, west of the Blue Mountains; and Wollongong-Bulli, in northern Illawarra. A shaft has also been sunk on the shores of Port Jackson, but the mine is worked only intermittently. The famous Newcastle coalfield is now practically worked out. All these fields belong to the great coal-basin; the Trias-Jura coal of the Clarence district is suitable only for local use. Silver production, mainly from the mines at Broken Hill (with lead and zinc) in 1919–20 diminished almost to extinction on account of constant strikes. Gold was discovered in 1851, but the Victorian fields soon outdid the New South Wales yield. Nowadays alluvial gold is chiefly won by dredging, in the Araluen, Adelong, and Gundagai valleys of the southern tableland; the chief quartz-mining areas are near Canbelego on the western plains, and Hillgrove on the northern tableland, but both are almost abandoned. Copper was first mined for in 1844, but the Cobar district, which became the State's main source of copper, was not touched till 1869. The drop in prices of 1919 affected it so seriously that by 1921 it had practically vanished. Tin shows a somewhat steadier yield, chiefly from the Inverell and Emmaville districts on the western slopes of the northern tableland; a new field at Ardlethan in the western plains has been found profitable. The extensive deposits of iron ore, whose existence has long been known, have been of late years systematically developed. The yield of other minerals is commercially of little importance; attempts to develop profitably known deposits of oil-shale have not succeeded, but there are valuable deposits of various clays and pigments, magnesite and tripolite, and at Bulladelah (north of Newcastle) there is the most remarkable deposit of alunite known in the world.

In manufactures New South Wales, largely because of its free trade policy, was, for many years before federation, of much less importance than protectionist Victoria; but when the common federal tariff more or less equalised conditions,

the larger State gradually caught up. Except the great steel works at Newcastle and Lithgow, and the smelting works at Newcastle and Port Kembla, New South Wales has no special lines of manufacture; its clothing and food manufacturing industries are conducted much on the same scale as those of other States, the actual factories being on the whole fewer and larger. The metal works, however, are particularly subject to strikes and the consequent disintegration of industry.

Agriculture, though practised in various forms from the earliest days of the colony, was of little importance for more than a hundred years. Up to 1892 the area farmed had never exceeded an acre per inhabitant; ten years later the proportion had doubled, and in the early years of the Great War more than trebled, but has since declined to pre-war level—about 2 acres per inhabitant, mostly in wheat. The sugar yield, which in the last century was an important part of New South Wales agriculture, fell off greatly in the first years of this century. This was due to the discovery that the north coast valleys and deltas, in which sugar had been grown previously, were admirably fitted for dairying; when, therefore, the introduction of cold storage on the mail-boats enabled dairymen to send their produce direct to the European markets, not only were the cane-fields regrassed for cattle pastures, but a huge area of forest was brought under settlement. In the period 1901–11 the production of butter alone grew from 39,000,000 to 83,500,000 lb., most of it coming from the north-coast districts; while the south-coast farmers supplied Sydney with milk, and made cheese. During and since the war, however, the yield of butter steadied at a lower level. The wheat district lies mainly along the western slopes of the main range; it is at present bounded (roughly speaking) by a line drawn from Moree in the north through Condobolin to Swan Hill on the Murray, which corresponds in most districts to the western limit of 10-inch rainfall between April and October; but south of the Lachlan towards Lake Cargelligo and Hillston, and along the Murray towards Balranald, good crops are obtained on a smaller rainfall. Near Goulburn the wheat-growing area extends across the main range eastward to the upper Shoalhaven. The production has of late years varied between 20,000,000 and 50,000,000 bushels, averaging 11 bushels to the acre; 'bumper' crops in 1915 and 1920 reached 67,000,000 and 56,000,000 bushels respectively. Oats and barley (grown for hay) are hill crops; potatoes also, mainly round Bathurst; maize, grown usually as feed for the dairy herds, is a staple of the coast, averaging from 18 to 30 bushels per acre. (This illustrates a weakness of New South Wales agriculture, the tendency to evade rotation and use the same area for the same crop year after year; in the ten years preceding the war the average maize crop ranged from 40 to 44 bushels.) *Paspalum* grass occupies much of the north-coast pastures, while at the western edge of the tablelands, especially where irrigation is possible, lucerne is a favourite fodder crop. Wine grapes are cultivated and good wine is made near Albury on the Murray, and in the valley of the Upper Hunter; table grapes and citrus fruits round Sydney; English fruits on the tablelands; the northern rivers produce semi-tropical fruits, and near Wagga the fruit-drying industry has been started with success. Timber-felling is, on the whole, carelessly conducted; the State until lately was slow to make, and negligent in enforcing, the regulations necessary for the proper use of existing forests and the reforestation of depleted areas. Fishery has been even more neglected, although the coastal waters are full of edible fish,

and the lagoons afford excellent breeding-grounds; but of late years some attention has been paid to this industry—in 1906 a State hatchery was established on Port Hacking, south of Sydney, and in 1915 three steam trawlers, under government control, began to supply the public (through State retail depots) with excellent fish trawled at less than three hours' steaming distance outside Port Jackson. This enterprise, however, was wastefully managed, lost a great deal of public money, and was closed down in 1923. Refrigerating stations have also been built at Newcastle, Port Stephens, and the Clarence River to store fish caught by local fishermen.

Trade.—The overseas trade of New South Wales has for many years exceeded that of any other State, and is still growing proportionally. More than nine-tenths of it is of internal origin or destination, the rest being in transit to or from other States. As might be expected from the account of industries already given, the chief export is wool, which accounts for nearly 40 per cent. of the total Australian export; for butter and wheat the proportion is about a quarter, for silver four-fifths, for coal practically the whole. The imports from other States, chiefly either foodstuffs or ores for smelting, are balanced by exports to them of coal, &c. (see AUSTRALIA, SYDNEY). Trade within the State is facilitated by about 5500 miles of railway, forming a comparatively aimless network of lines constructed to suit local needs and temporary conditions of finance; when the lines now under construction are completed, the State will have two main lines into Queensland (one along the coast, the other on the New England tableland), one to Melbourne, and one across the inland plains to Broken Hill and South Australia—this is intended to connect up with the federal trans-continental line, and give a direct route from Sydney to Perth. A very important branch line (Binnaway to Werri Creek) opened in 1923 gives for the first time through communication between northern and southern Australia by an inland route, safe from coastal attacks: until its opening the only through line passed over the Hawkesbury Bridge, which is close to and easily accessible by water from the open ocean.

Government.—The State, while for certain purposes administered by the federal government (for which see AUSTRALIA), has still sovereign rights over its lands, railways, education, internal trade, &c. The State governor is appointed by the imperial government for a period of five years. His personal powers, apart from those exercised as the head of the executive council, include that of withholding the royal assent from certain classes of bills and that of granting or refusing a dissolution. The Legislative Council consists of nominees for life—there must be at least 21 members, but the usual number is about two-thirds of the Assembly, i.e. 60. Of late years this proportion has been considerably exceeded, in order to 'swamp' the House with members favourable to its abolition. The Legislative Assembly of 90 members is elected under a system of proportional representation, nine electorates returning 5 members each and fifteen returning 3 each. Until lately members were paid £500 a-year; but in 1921 the amount was increased to £875, and in 1922, after an election at which this increase was one of the issues, reduced to £600.

The population has grown from 1,377,648 in 1901 to 2,189,379 in 1923. (These figures are taken from the federal statistician's publications; the State statistician, for some reason, lessens the first and increases the second computation slightly.) There is a small preponderance of males. The excess of births over deaths is about 16½ per

thousand. About 1 per cent. are of non-European blood; and 1500 full-blooded aboriginals are not included in the total. Over 85 per cent. are Australian-born, and another 12 of British birth. A disquieting feature of the growth is its distribution between town and country. In 1901 less than 36 per cent. of the population was settled in the metropolis; by 1921 the proportion had risen to 43. The percentage of the purely rural population has at the same time sunk from 37 to 32, and that of the population within extra-metropolitan municipalities from 27½ to 25. To put it in another way, in twenty years the population of an already over-grown metropolis increased by nearly 420,000, while all the rest of the State only acquired 330,000 new inhabitants.

See AUSTRALIA and works there cited; also the State's *Official Year Books and Statistical Register*. The *Historical Records of New South Wales* (8 vols. ending with 1811) contain many documents not to be found in the *Historical Records of Australia*, which, as far as New South Wales is concerned, are so far almost entirely confined to governors' despatches. Sir Henry Parkes's *Fifty Years in the Making of Australian History* is valuable, despite its obvious bias, for the political history of the period 1842-93; Dr Lang's *Historical and Statistical Account of New South Wales* gives with greater bias another point of view. An excellent summary of facts of all kinds about the colony covering the period up to 1914 is given in the *Handbook to New South Wales* published in Sydney in connection with the visit of the British Association for the Advancement of Science; this was compiled by experts in all the subjects treated of, and a reprint, if brought up to date, would be of great value.

Newspapers.—Ancient Rome and China had the honour of introducing the newspaper. As early as the 1st century the Roman government issued daily bulletins of official news called the *acta diurna*. These were posted in public places, and circulated to the generals in command of the different armies. These *acta diurna* ceased when the Western Empire fell, about 476 A.D. The *Peking Gazette*—to use its foreign name—has been published regularly since 618 A.D. It was not, however, until the introduction of printing from movable type (about 1450) that anything resembling the modern news-sheet was issued. In this respect the Germans were the pioneers. German news-sheets were started in the early part of the 16th century. The newspaper industry began in England in 1622, when Nathaniel Butter issued the *Weekly News*. The *Oxford Gazette*, predecessor of the *London Gazette*—still the government official organ—first appeared in 1665.

It is estimated that the aggregate number of newspapers in all countries amounts roughly to 34,000, of which 2000 are published in Great Britain and Ireland, 184 being dailies and evenings, 18 Sunday, and 1798 weeklies, but it is difficult to procure precise information regarding newspapers in other countries. The estimate must be taken subject to this proviso.

Cheap paper, the rotary printing-press, and the electric telegraph revolutionised the production of newspapers. These changes date back to 1870, but their full effect was not felt until some twenty-five years later. The result has been an amazing increase in the number of publications and in the size of circulations. Cheap paper was due to the introduction of wood pulp as a paper-making material (see PAPER). Vast forests are now cut down each year in Canada, Newfoundland, Norway, Sweden, and Finland to supply the millions of tons of paper required to produce the newspapers and periodicals of the world. Prior to 1814 all newspapers were printed on hand-driven machines. In that year Mr John Walter, of the *Times*, installed a machine driven by steam, but the practice did

not become general until the introduction of the rotary printing-press, which prints from rolls of paper, the sheet being passed through rapidly revolving cylinders on which are fixed circular metal plates containing stereotyped reproductions of the page as set up in type. The modern rotary presses print at almost incredible speed. Sixteen-page papers can be produced complete at 36,000 per hour (see PRINTING). The first practical rotary, invented by Augustus Applegath, was installed at the *Times* in 1848 by Walter the second, but the machine did not come into general use until much later. Simultaneously with the provision of cheaper paper and improved machinery, increased cable, telegraphic and telephonic facilities entirely revolutionised the collection and distribution of news. Vast news-gathering organisations have been established in most civilised countries. The chief are: in Britain, Reuters, which has world-wide connections, the Press Association, a co-operative society comprising the newspapers of the United Kingdom and Ireland, and allied with Reuters, the Central News, and Exchange Telegraph Company; in America, the Associated Press, the United Press and International News Agency; in France, the Havas Agency; in Germany, the Wolff Agency; in Italy, the Stefani Agency; in Belgium, the Agence Télégraphique Belge; in Spain, the Fabra Agency; in Holland, the Nederlandsch Telegraaf Agentschap; and in Japan, the Kokusai Agency.

Most of these are ordinary commercial undertakings. Many work in co-operation, so that the news collected in one country is available for newspapers elsewhere. By these means the most important parts of the world are bound together for news-gathering purposes. What is collected in Britain, for instance, is available for France, Germany, America, &c. The news agencies in each country are represented by correspondents in the various districts. Most of them are attached to local newspapers, each of which collects the news in its own district. In Britain and America the bulk of the news is supplied to the newspapers by news agencies, but leading papers in all countries have their own correspondents in most of the principal centres both at home and abroad. Large sums are spent in telegraphing or cabling news and comment. Information is often communicated and published with extraordinary rapidity. For instance, when peace was signed at Versailles, the London evening newspapers announced the fact within three minutes after the signatures had been affixed. In Britain, reports of parliamentary proceedings, law reports, and public speeches are usually supplied by the news agencies. In Britain the art of shorthand reporting has been highly developed. In America it is little used.

The modern press has been revolutionised by many important innovations, of which the chief are:—

1. *Illustration by what are known as Half-tone Blocks* (see ILLUSTRATION OF BOOKS).—These blocks, produced by photography, and mostly from photographs, superseded the line engraving in the weekly illustrated papers, such as the *Illustrated London News*, *Graphic*, and *Sphere*, about the year 1890. In the same year the *Daily Graphic*, the first daily illustrated, was published. But it was not until 1904, when the *Daily Mirror* was converted into a picture paper, that daily illustrated journalism achieved its present-day popularity. The success of the *Daily Mirror* led to the publication of half-tone illustrations in the daily, evening, and Sunday papers throughout the country. This may be regarded as a most important journalistic epoch. These activities gave rise to a new pro-

fession, that of the press photographer, one of the most adventurous and daring types in history. These photographers are prepared to take any risks to secure a good picture, even in some cases the risk of unpopularity with their victims.

2. *The Woman's Page—Catering for the Requirements of Feminine Readers.*—Prior to 1895 newspapers did very little for women, except by providing their readers with plenty of scandal. Before 1860 or thereabouts in this respect the press displayed a degree of licence never since equalled. Newspapers of the highest degree published personal paragraphs, the like of which are never seen nowadays. The provision for women readers has not been confined to the woman's page. Many leading English papers now publish serial fiction. This idea was borrowed from France. Generally speaking, this sort of fiction is written by experts who understand the true significance of the phrase, 'To be continued in our next.'

3. *News Treatment.*—The hurry and complexity of modern life, and the creation by the Education Act of 1870 of a new class of reader, inevitably led to the *Tit-Bits* style, first exemplified by that perceptive genius, Sir George Newnes, in 1881. The success of *Tit-Bits* showed journalists, and notably Lord Northcliffe, undoubtedly the outstanding figure of modern journalism, that the public wanted shorter and snappier paragraphs in the newspapers, and more information about the simple things of life. The period when the press enlivened its columns by more or less authentic paragraphs concerning the private lives of more or less distinguished people was followed for the most part by a period of stately dullness, only lit up by occasional verbatim reports of *causes célèbres*. The *Daily Telegraph*, built up by the journalistic skill of the Burnham family, was a notable exception. But the *Daily Telegraph* had a style all its own, of which brevity was not a distinguishing characteristic. The *Daily Mail*, established in 1896, marked a new epoch in daily journalism. Its founder prided himself on picking out the eyes of the news. But this feature was usually supplemented by what unfriendly critics would describe as a 'stunt'—in other words, by lengthy treatment of some startling subject, such as German armaments, standard bread, sweet peas, &c. Another new feature was the adoption, from the *Globe*, now defunct, of brightly-written column articles on subjects of general interest. The leaders also were written in a new style—to use a journalistic phrase, 'with more punch'—and not too long. In the new journalism features and paragraphs were embellished with striking headlines, in marked contrast to the old-fashioned conventional style. It must be admitted, however, that much of this journalistic atmosphere was imported from America, where its protagonist was Mr Pulitzer, the emperor of yellow journalism. The *Daily Mail* was published at one halfpenny, but was not the first London halfpenny morning daily, having been preceded by *The Morning*, issued on 21st May 1892, and the *Morning Leader*, issued on the 23d May 1892. *The Morning* had a short life, but introduced to the British public most of the features of modern journalism. The *Morning Leader* has long since been incorporated with the *Daily News*. The journalistic revolution led to intensified treatment of all departments of information—sport, finance, shipping, markets, literature, &c. To-day most papers devote a large amount of space to racing, football, boxing, and golf. The evening papers issue early editions giving racing news, and every daily, evening, and weekly newspaper has its sporting correspondent, who not only comments upon current events, but provides its readers with prognostica-

tions or 'tips.' Football is one of the best sellers, and most evening papers throughout Britain issue on Saturdays football editions which have enormous circulations.

4. *The Extension of Advertising.*—The vast and varied activities of the modern press involve huge expenditure. To provide this, newspaper proprietors have found it necessary to pay ever-increasing attention to their advertising columns. In former days the advertiser was kept within strict limits. Many newspapers refused to publish display or full-page advertisements. To-day newspapers do their best to cater for the advertiser, and to provide him with full value for his money. Advertising has become a fine art, and advertisement-writing and the placing of advertisements a profession employing large numbers of skilled persons known as advertising agents.

5. *Improved Size, Type, and Make-up.*—The extended scope of newspapers in influence, features, and advertisements has necessitated a great increase in size, rendered possible, as has been said already, by cheap paper, the rotary press, and increased advertisement revenue. Types have also increased in size as compared with former days. The make-up of newspapers and the display of news has also become a fine art.

6. *The Contents Bill.*—The old-fashioned contents bill, containing a number of items in small type, has given place to a bill with not more than three lines in large heavy lettering. Many newspapers use their contents bills as a sort of slogan, intended not only to sell the paper but to emphasise a point of view.

7. *Vast Increase in Circulations.*—In all parts of the world the circulations of newspapers have largely increased, but those of London and Paris still predominate because they have national sales. French newspapers achieve this result by publishing numerous editions circulating throughout France, while the size of Britain, and the excellence of its railway service, enable London newspapers to reach most parts of the country in time for the breakfast-table. In America conditions are different and the sales much smaller. The circulations of the *Daily Mail* and *Daily Mirror* are in the neighbourhood of two million each, while the *Daily Chronicle*, *Daily News*, and *Daily Express* also have huge sales. Those of the *Times*, *Daily Telegraph*, and *Morning Post*, sold at 2d., and catering specially for a different class of reader, are considerably smaller.

8. *The Growth of the Sunday Press.*—Sunday newspapers appealing to the mass of the people have always enjoyed large circulations. Early in its career the *News of the World*, started in 1843 at 3d., had a sale of 250,000 per week—a huge figure in those days. It was followed by *Lloyd's News*, which also attracted a large number of readers. To-day the *News of the World* has a circulation of 3½ millions. The *Sunday Pictorial*, the *Sunday News*, formerly *Lloyd's News*, the *Weekly Dispatch*, *Sunday Express*, *Reynolds's*, the *People*, the *Empire News*, and *Sunday Chronicle*, all have large sales. The aggregate sale of Sunday papers is said to be about 12 millions.

9. *The Growth of the Provincial Press.*—Since 1880 the provincial press has made remarkable progress in importance and circulation. Great papers like the *Scotsman* (as a daily, 1855), *Glasgow Herald* (as a daily, 1858), *Liverpool Post* (as a daily, 1853), *Manchester Guardian* (1855), *Yorkshire Post* (1866), *Sheffield Telegraph* (1855), *Western Mail* (1869), *Birmingham Post* (1857), *South Wales Daily News* (1872), *Western Morning News* (1860), *East Anglia Times* (1874), and others provide their readers not only with local news, but with first-class services of general information.

The circulations of provincial morning papers are limited, but what they lack in numbers they make up in quality, being read by the more influential classes in their respective districts. Probably the sale of no provincial morning exceeds 100,000 per day. But the most marked feature of provincial journalism is the growth in number and importance of evening newspapers. In the chief centres their circulations run into big figures, such as 200,000, 300,000, 400,000, and 500,000. There is hardly a town of any importance that does not possess its evening paper. The aggregate sale of evening papers throughout Great Britain is estimated at six and a half millions.

10. *Improved Methods of Distribution.*—Newspapers are now distributed by means of a vast and complex organisation, employing every type of transport, from aeroplanes and special trains to push bicycles.

11. *Ownership by Companies.*—Formerly most newspapers were owned by individuals, but at the present time practically all the chief newspapers in Britain are owned by companies, many of which have large capitals, and some of which are public companies with thousands of shareholders. Many of these concerns control groups of publications, and are linked up with other concerns controlling other groups.

12. *Organisation of the Trade.*—In Britain the newspaper trade is perhaps the most highly organised of all trades. Employers are united in the Newspaper Proprietors' Association, representing the London daily, evening, and Sunday newspapers, and the Newspaper Society, representing the provincial press. The journalists are represented by the National Union of Journalists and the Institute of Journalists, and the various sections of mechanical workers by their respective trade unions. There is also a Society of Women Journalists. The wholesale and retail newsagents also have their respective associations.

13. *The Trade and Technical Press.*—In Britain, America, France, and Germany there are now large numbers of weekly newspapers dealing with scientific and technical subjects. Every profession and trade has a publication, or publications, devoted exclusively to matters affecting its interests. Some of these publications are very valuable properties, and are conducted with much knowledge and skill. Many of them largely consist of advertisement pages, alike informative for the reader and profitable for the proprietor. In Britain there are at least 450 trade and technical publications.

The Advance of Weekly Illustrated Newspapers.—The *Illustrated London News*, started in 1842, was the first illustrated newspaper of the modern type. It has been followed by many others in most civilised countries. In Britain, the *Graphic* and *Sphere* are two of its most notable successors. Many of these illustrated papers are works of art. They are usually sold at one shilling. Some are devoted more or less to sectional interests. *Country Life*, for instance, as its name implies, is chiefly concerned with country houses and country pursuits. Illustrateds like the *Tatler*, *Sketch*, and *Bystander* are mostly devoted to illustrating the glories of society.

Production of Newspapers.—A newspaper office comprises five departments—editorial, mechanical, commercial, publishing, and advertisement. The two chief executive officers are the manager and editor. Other head officials are the works manager, publisher, and advertisement manager. The editorial staff usually consists of the assistant editor, the news editor, the financial editor, the sports editor, the literary editor, the leader writers, and last, but not least, the sub-editors, reporters, and contributors. The news editor is responsible

for collecting the news, and ensuring that all forthcoming events are covered. The sub-editors are responsible for the treatment of the 'copy' as it is called. They cut down, write up or re-write what goes into the paper, and are also responsible for the headlines. The copy is then passed to the composing room, where it is set up, usually on linotype machines. The proofs are then checked by the 'readers' and submitted to the sub-editors. After the pages have been made-up in the composing room, they are passed to the stereotyping room, where the cylindrical plates are cast. These are then passed to the machine room, where they are fixed upon the presses. The copies are delivered by the machines ready counted for distribution. All these operations are performed in an incredibly short space of time, so that in some instances within a quarter of an hour after the copy has been received by the sub-editor it is published in the paper.

Power and Influence of the Press.—Burke described the press as the 'Fourth Estate,' implying, of course, that the other three were King, Lords, and Commons. Although this phrase is frequently used, it is neither happy nor accurate, as, unlike King, Lords, and Commons, the press has no executive power. It is purely a reportorial and critical institution. During recent years its influence has increased enormously. As the servant of the public it has secured all sorts of privileges for collecting and distributing information. The severity of the libel laws has been mitigated in regard to the publication of the reports of meetings and other matters of public interest. It is difficult to analyse or accurately to appraise the influence of the press. According to Lord Northcliffe, the chief power of the press is 'the suppress'—i.e. silence. But it may be noted that two at least of the epoch-making movements of modern times received little notice from the press until they had arrived, viz. Woman's Suffrage and the formation of the Labour Party, with their respective implications.

The truth seems to be that while vital movements are bound to make way, whether noticed in the press or not, press publicity can do much to further them. It also seems clear that no movement advocated by the press can hope to secure permanent support unless it has the sympathy and is based on the necessities of a large section of the public.

According to post-office regulations, a newspaper can only be registered as such under the following conditions:—(a) The publication must consist wholly or in great part of political or other news, or of articles relating thereto, or to other current topics, with or without advertisements. (b) It must be printed and published in the British Islands, or in some British possession or protectorate (including the Malay States). The Postmaster-General may refuse to register as a newspaper a publication printed and published in a British possession or protectorate unless arrangements have been made to his satisfaction for maintaining a responsible representative of the publication in Great Britain. (c) It must be published in numbers at intervals of not more than seven days. (d) The full title and date of publication must be printed at the top of the first page, and the whole or part of the title and the date at the top of every subsequent page. This regulation applies also to 'Tables of Contents' and 'Indexes.' (e) Any supplement issued with a newspaper must consist wholly or in great part of matter like that of a newspaper, or of advertisements, or engravings, prints, or lithographs illustrative of articles in the newspaper; it must in every case be published with the newspaper, and

have the title of the newspaper printed at the top of every page. Supplements may not exceed the newspaper itself in size or weight.

OVERSEAS NEWSPAPERS.—There are many powerful daily and weekly newspapers published in the Dominions. Some of the chief are the *Sydney Morning Herald* (the oldest Australian paper), the *Melbourne Age* (1854), the *Melbourne Argus* (1846), the *Brisbane Courier* (1846), the *Cape Argus* (1857), the *Cape Times* (1876), the *Natal Mercury* (1852), the *Rand Daily Mail*, the *Toronto Globe* (1844), the *Montreal Star* (1869), the *Montreal Herald* (1811), the *Calcutta Englishman* (1833), and *The Statesman* (1873).

Canada has 1202 newspapers, of which 116 are dailies and evenings, 3 Sunday, and 1083 weeklies.

Australia has 844, of which 84 are dailies and evenings, 10 Sunday, and 750 weeklies.

New Zealand has 222, of which 62 are dailies and evenings, and 160 weeklies.

South Africa has 175, of which 24 are dailies and evenings, 2 Sunday, and 149 weeklies.

The *Newspaper World* is the organ of the British press. Price 2d.

America is said to boast 17,327 newspapers, of which 2421 are dailies and evenings, 50 Sunday, and 14,856 weeklies. More than 1000 are published in foreign languages. Mostly American dailies are published seven days a week. The Sunday newspaper is one of the chief features of American journalism. It is usually made up in several sections profusely illustrated, each section being devoted to some special subject, such as sport, real estate, women and children, finance, comics, &c.

Germany has 3167 newspapers, of which 2055 are dailies and evenings, and 1112 weeklies.

France has 1288, of which 225 are dailies and evenings, and 1043 weeklies.

Italy has 488, of which 148 are dailies and evenings, and 340 weeklies.

The Press of Britain.—In London: *The Times* (2d.), started 1785 by John Walter, carried on by the Walter family until 1908, when the paper was acquired by a company formed by Lord Northcliffe. On his death in 1922 his shares were purchased by Major Astor, M.P. Now vested in a trust with object of ensuring that the paper shall be conducted as a national organ. *The Daily Telegraph* (2d.; Conservative), started 1855 by Colonel Sleigh. Acquired shortly afterwards by Mr Joseph Moses Levy, grandfather of Viscount Burnham, present managing proprietor, now assisted by his nephew Colonel Lawson. Viscount Burnham is chairman of the Newspaper Proprietors' Association, Empire Press Union, and Newspaper Press Fund. *Morning Post* (2d.; Conservative), started 1772. Now owned by company formed of leading Conservatives. *Morning Advertiser* (2d.), started 1794. Owned by Association of Licensed Victuallers. Represents the trade. *Daily News* (1d.; Liberal), started 1846. Edited by Charles Dickens from January to March in that year. Now owned by company in which shares are chiefly held by the Cadbury family. Absorbed *Morning Leader*, one of the first halfpenny papers, in 1812. Company also own *Star* (1d.) evening newspaper, started 1888. *Daily Mail* (1d.; Independent), started 1896 by Lords Northcliffe and Rothermere and late Mr Kennedy Jones at price of 3d. Increased to 1d. in 1917; owned by Associated Press Ltd.; also proprietors of *Evening News* (1d.), started 1881, and *Weekly Dispatch* (2d.), started 1810; control continental *Daily Mail*. Shares in company widely held by public, but principal shareholder Viscount Rothermere. Chairman, Mr Thomas Marlowe; deputy chairman, Sir Andrew Caird. *Daily Chronicle* (1d.; Liberal), established 1855 as *Clerkenwell News*. In 1904 price reduced to 3d. Raised to 1d. in 1917. Now owned by United Newspapers (1918), Ltd. Bulk of shares held by Lloyd George interest. Editor, Mr Ernest Alfred Ferris. Company also owns *Sunday News* (2d.), started 1842 as *Lloyd's News*. *Daily Express* (1d.; Independent), started 1900 by late Sir Arthur Pearson. Now controlled by Lord Beaverbrook and Mr Ralph D. Blumenfeld, editor since 1904. *Daily Herald*

(1d.; Labour), started 1912. Owned and controlled by trade unions. *Westminster Gazette* (1d.; Liberal), started 1893 as evening paper. In 1921 converted into morning paper, owned by company in which Lord Cowdray is understood to be chief shareholder. *Daily Mirror*, picture paper (1d.; Independent). Started 1903 by Viscount Northcliffe. Owned by company controlled by Viscount Rothermere. Associated with *Sunday Pictorial* (2d.), started 1915, published from same offices and owned by similar company. *Daily Graphic* (1d.; Independent), started 1890. First daily picture paper. Owned by company controlled by Messrs Berry. *Daily Sketch* (1d.; Independent), started 1910 by Sir Edward Hulton. Associated with *Illustrated Sunday Herald* (2d.), started 1915, published in same offices. Now owned by company controlled by Viscount Rothermere. Managing director, Mr James Heddle. *Evening Standard* (1d.; Independent), started 1827. Now owned by company controlled by Lord Beaverbrook. *Financial News* (2d.), started 1884. Owned by company. *Financial Times* (2d.), started 1888. Owned by company controlled by Messrs Berry. *Sporting Life* (2d.), started 1859. Owned by company controlled by Messrs Odhams.

Sunday Newspapers.—*News of the World* (2d.; Independent), started 1843. Owned by company of which Lord Riddell is chairman. Editor, Sir Emsley Carr. *Observer* (2d.; Conservative), started 1791. Owned by Lord Astor. Editor, Mr J. L. Garvin. *Sunday Times* (2d.; Independent), started 1822. Owned by company controlled by Messrs Berry. Editor, Mr Leonard Rees. *Reynolds's* (2d.; Liberal), started 1842. Owned by company controlled by Lord Dalziel. *People* (2d.; Conservative), started 1881. Owned by company controlled by Messrs Odhams. *Referee* (2d.), started 1877. Devoted to theatrical and sporting matters. Owned by company controlled by Sir Oswald Stoll.

The chief Irish papers are *The Irish Times* (1859), *The Belfast News Letter* (1737), *The Belfast Evening Telegraph* (1870), *The Dublin Daily Independent* (1891).

The chief weekly reviews are *The Spectator*, started 1828; *The Nation*, started 1890; *The New Statesman*, started 1913—all sold at 6d.; and *Truth*, started 1877 (9d.).

The chief weekly financial papers are *The Economist*, started 1843 (1s.); *The Statist*, started 1878 (6d.); *The Investors' Review*, started 1892 (6d.); *The Investors' Guardian*, started 1863 (6d.).

The chief comics are *Punch*, started 1841 (6d.); *London Opinion*, started 1904 (2d.); *The Humorist*, started 1922 (2d.).

The religious press is represented by *The Guardian* (2d.), Church of England (1846); *Church Times* (2d.), Ch. Eng. (1863); *Church of England Newspaper* (2d.), Ch. Eng. (1894); *Christian World* (2d.), Nonconformist (1857); *British Weekly* (2d.), Nonconformist (1886); *The Tablet* (6d.), Roman Catholic (1840); *The Universe* (2d.), R.C. (1860); *Catholic Times* (2d.), R.C. (1860); *Catholic Herald* (2d.), R.C. (1888).

Lloyd's Shipping List (1s.), published by Lloyd's Insurance Corporation, gives a daily account of arrivals, departures, wrecks, &c. Daily shipping publications are also issued at Liverpool, Glasgow, and Cardiff.

Newstead Abbey, 10 miles NNW. of Nottingham, on the border of Sherwood Forest, was founded for Augustinian Canons by Henry II. in atonement for Becket's murder (1170), and in 1540, after the dissolution, was given to 'Sir John Byron the Little, with the great beard.' Among his descendants were the first Lord Byron (cre. 1643), the 'wicked Lord Byron' (1722–98), and the poet Lord Byron (q.v.), who made the half-ruins old place his home in 1808, but sold it in 1818. See Washington Irving's *Abbotsford and Newstead* (1835).

Newt, or EFT (*Triton* or *Molge*), a genus of tailed Amphibians (Urodela), in the same family as the Salamanders (q.v.). The gills are absorbed

in youth (Caducibranchiate); the eyes have movable lids (except in the blind Typhlotriton of the Rock House Cave in Missouri); there are teeth on both jaws and on the palate; there are always four fingers and five toes; the tail is laterally compressed, and often bears a permanent fin. The majority of the newts are European, but the genus has representatives in western Asia, north-eastern China, Japan, Algeria, and North America (*T. torosus* and *T. viridescens*). In regard to all the species the following statements may be made: they like cool, damp places, they betake themselves to water during the prolonged breeding season; they are normally oviparous, the youthful stages are strictly aquatic; the winter is passed in a lethargic state in the ground, or occasionally in ponds; the food consists of insects, worms, slugs, snails, and the like, and is chiefly sought for at night; they do not drink, but water is absorbed through the skin; the outermost layer of the epidermis is shed periodically, and especially during the period of rapid growth it is turned inside out from the head backwards, and typically comes off as a whole; it is eventually swallowed. As to the development and life-history: propagation usually takes place in spring; the excited male, more brightly coloured than the female, plays about his mate, and in some species embraces her; he emits at intervals spermatophores (packets of spermatozoa) which sink to the bottom; the females take these up into the cloaca, so that fertilisation is internal; the eggs are glued singly or in small numbers to stones or water-plants, and are hatched in about a fortnight; the larvæ have three pairs of branched external gills, and in most (if not all) cases two pairs of thread-like protuberances on the sides of the upper jaw, by which they moor themselves to water-plants for some time after hatching; the metamorphosis is normally accomplished by the end of summer, but some retarded individuals may pass the winter as larvæ. Total 'neoteny,' where the animal retains some larval features, such as gills, and yet becomes sexually mature, is known in *Triton cristatus*, *T. vulgaris*, *T. alpestris*, and some other newts.

The skin of newts is warty, moist, rich in glands, and with numerous sensory cells, especially along the lateral lines of the body and tail; the males of some species develop a high skin-crest along the back, which is non-muscular but rich in sensory cells; the tail-fin helps in the undulatory movements of swimming, in which the weak limbs are of very little account; the internal organs, such as the three-chambered heart, are, in general, like those of frogs; there is a notable capacity of regenerating fingers and toes to replace those that have been bitten off.

There are three British newts. The Crested Newt (*Triton cristatus*), 5 to 6 inches in length, is

Fig. 1.—The Crested Newt (*Triton cristatus*)

dark brown above, with an olive tinge interspersed with spots, which are dark above and white on the sides; the under parts are yellow with dark spots; the breeding male has brighter coloration, and a high notched or serrate dorsal crest. The Common or Spotted Newt (*T. vulgaris*), 3 inches in length, is olive-green or brown above, spotted with black, and inclining to white on the flanks, yellow and

orange on the under surface with black spots; the breeding male has a high crest, wavy instead of serrate, and his tail shows a blue stripe; the larvæ are marked by yellow dots. The Palmate Newt (*T. palmatus*) is a little smaller than the Common Newt. The general colour is olive-brown above

Fig. 2.—Larvæ of *Triton cristatus*.

A, condition before leaving the egg; B, larva shortly after it is hatched; C, at about the twenty-second day; D, at about the forty-second day.

with dark spots, yellow and orange below with dots; the tail of the male ends in a thread, just indicated in the female; the breeding male has a low median crest, a fold of skin along each side of the back, and markedly webbed feet.

The Alpine Newt (*T. alpestris*) ascends the Alps to 7000 feet, but is also found in the Netherlands. The Pyrenean newt (*T. asper*) occurs at high levels up to about 7000 feet. The Iberian newt (*T. waltii*) sometimes shows a curious perforation of the skin by the long ribs, a peculiarity also seen in *Tylostrotion andersoni* from the Ryukyu Islands. The newt of western North America is *Triton torosus*, reaching a length of 6 inches; in the northern and eastern parts of the United States its place is taken by *T. viridescens*, with a greenish tinge.

Newts are interesting inmates of aquaria, easily reared and kept. The words *newt* and *eft* are really identical, a *newt*=an *eft*. O.E. *efeta*, just as an *adder*, resulted from a *nadder* by mistake. For newts in general, see Gadow, 'Amphibia and Reptiles,' vol. viii. of *Cambridge Natural History*, 1901.

Newton, (1) capital of Harvey county, Kansas, 134 miles by rail SW. of Topeka, is the centre of a rich coalfield. Pop. 10,000.—(2) A city of Massachusetts, 7 miles WSW. of Boston by rail, and almost surrounded by the Charles River. It contains many suburban residences belonging to citizens of Boston, and has manufactures of cotton, paper, silk, machinery, &c. Pop. (1860) 8382; (1890) 24,379; (1900) 33,587; (1920) 46,054.

Newton, SIR ISAAC, the greatest of natural philosophers, was born on 25th December (o.s.) 1642—a year remarkable in English history for the breaking out of the Civil War, and doubly remarkable in the history of science by the birth of Newton and the death of Galileo. The farmhouse he was born in, still preserved religiously, is at the hamlet of Woolsthorpe in Colsterworth parish, Lincolnshire, 8 miles S. of Grantham (q.v.), at whose grammar-school the boy received his early education. On the 5th of June 1661 he left home for Cambridge, where he was admitted as subsizar at Trinity College. On the 8th of July following he matriculated as sizar of the same college. He immediately applied himself to the mathematical

studies of the place, and within a very few years must have not only made himself master of most of the works of any value on such subjects then existing, but had also begun to make some progress in the methods for extending the science. In 1665, in which year he took his B.A., he committed to writing his first discovery on fluxions; and in 1666, according to Voltaire's *Lettres sur les Anglais* (1733), the fall of an apple, as he walked in the garden at Woolsthorpe, suggested the most magnificent of his subsequent discoveries—the law of universal gravitation. On his first attempt, however, by means of the law so suggested to his mind, to explain the lunar and planetary motions, he employed an estimate then in use of the radius of the earth which was so erroneous as to produce a discrepancy between the real force of gravity and that required by theory to explain the motions, corresponding to the respective figures 16.1 and 13.9. He accordingly abandoned the hypothesis for other studies. These other pursuits to which he thus betook himself consisted chiefly of investigations into the nature of light, and the construction of telescopes. By a variety of ingenious and interesting experiments upon sunlight refracted through a prism in a darkened apartment, he was led to the conclusion that rays of light which differ in colour differ also in refrangibility. This discovery enabled him to explain an imperfection of the telescope, which had not till then been accounted for. The indistinctness of the image formed by the object-glass was not necessarily due to any imperfection of its form, but to the fact of the different coloured rays of light being brought to a focus at different distances. He concluded rightly that it was impossible for an object-glass consisting of a single lens to produce a distinct image. He went further, and too hastily concluding, from a single experiment, that the dispersive power of different substances was proportional to their refractive power, he pronounced it impossible to produce a perfect image by a combination of lenses. This conclusion—since proved erroneous by the invention of the achromatic telescope (see ACHROMATISM)—turned Newton's attention to the construction of reflecting telescopes; and the form devised by him is the one which, at later periods, reached such perfection in the hands of Sir William Herschel and Lord Rosse.

Newton became a Fellow of Trinity in 1667; and Lucasian professor of Mathematics in 1669; and it was on 11th January 1671 that he was elected a member of the Royal Society, having become known to that body from his reflecting telescopes. At what period he resumed his calculations about gravitation, employing the more correct measure of the earth obtained by Picard in 1670, does not clearly appear; but it was in the year 1684 that it became known to Halley that he was in possession of the whole theory and its demonstration. It was on the urgent solicitation of Halley that he was induced to commit to a systematic treatise these principles and their demonstrations. The principal results of his discoveries were set down in a treatise called *De Motu Corporum*, and were afterwards more completely unfolded in the great work entitled *Philosophiæ Naturalis Principia Mathematica*, which was finally published about midsummer 1687.

Shortly before the *Principia* was given to the public Newton had been called to take an active part in defending the rights of the university against the illegal encroachments of James II. The conspicuous part which he had taken on that occasion procured him a seat in the Convention Parliament, in which he sat from January 1689 to its dissolution in 1690. In 1696 he was appointed Warden of the Mint, and was afterwards promoted to the office of Master of the Mint in 1699, an office

which he held till the end of his life. He again took a seat in parliament in the year 1701 as the representative of his university. Thus engaged in the public service, he had little time left for mere scientific studies—pursuits which he always held of secondary importance to the public duties in which he was engaged. In the interval of public duty, however, Newton showed that he still retained the scientific power by which his great discoveries had been made. This was shown in his solution of two celebrated problems proposed in June 1696 by John Bernoulli, as a challenge to the mathematicians of Europe. A similar mathematical feat is recorded of him so late as 1716, in solving a problem proposed by Leibniz for the purpose, as he expressed it, of feeling the pulse of the English analysts. When in parliament Newton recommended the public encouragement of the invention of a method for determining the longitude—the first reward in consequence being gained by John Harrison for his chronometer. He was president of the Royal Society from 1703 till his death, a period of twenty-five years, being each year re-elected. In this position he could do much for the advancement of science; and one of his most important works during this time was the superintendence of the publication of Flamsteed's *Greenwich Observations*—a task, however, not accomplished without much controversy and some bitterness between himself and that astronomer. The controversy between Newton and Leibniz as to priority of discovery of the differential calculus, or the method of fluxions, was raised rather through the partisanship of jealous friends than through the anxiety of the philosophers themselves, who were, however, induced to enter into and carry on the dispute with some degree of bitterness and mutual recrimination. The verdict of the impartial historian of science must be that the methods were invented quite independently, and that, although Newton was the first inventor, a greater debt is owing by later analysts to Leibniz, on account of the superior facility and completeness of his method. In 1699 Newton was elected a foreign associate of the Academy of Sciences, and in 1705 he received the honour of knighthood from Queen Anne. He died at Kensington on 20th March 1727, and his remains received a resting-place in Westminster Abbey, where a monument was erected to his memory in 1731. Roubilliac's magnificent full-length statue was erected in 1755 in the ante-chapel of Trinity College, Cambridge.

Besides the first edition of the *Principia*, other editions appeared in 1713, 1726, 1729, 1780; and at Geneva the Jesuits' edition (1739-42; republished at Glasgow, 1822). An admirable reprint is that by Lord Kelvin and Professor Blackburn (Glasgow, 1871). Clarke's Latin translation of the *Optics* appeared in 1706; the *Optical Lectures* in 1728; the *Fluxions* in 1736; and Horsley edited his collected works (5 vols. 4to 1779-85). Newton was a student of Alchemy (q.v.); and he left a remarkable monument of his interest in theology, especially prophecy, a MS. work on the prophecies of Daniel and on the Apocalypse, a history of the Creation, and a number of tracts. See the articles on ASTRONOMY, FLUXIONS, GRAVITATION, LIGHT, OPTICS, SPECTRUM; Sir David Brewster's *Life of Newton* (1855); and Augustus de Morgan's *Newton, his Friend, and his Niece* (1885), that friend being John Conduitt (1688-1737), Newton's successor as master of the mint, who in 1717 married Newton's niece, the 'gay and witty' Catherine Barton. See also Bloch, *La Philosophie de Newton* (1908), and G. G. Gray, *Bibliography* (1907).

NEWTON'S RINGS.—In his investigations of the colours produced by thin plates of any material, solid, liquid, or gaseous, Sir Isaac Newton hit upon the following mode of exhibiting the colours produced by reflection from a film of air. He took two lenses, one convexo-plane, its convex side

having a radius of 14 feet, the other equi-convex, with the radii of its surfaces 50 feet, and laid the first with its plane surface downwards on the top of the second, thus producing a thin film of air between the lenses; the film being thinnest near the centre, and becoming gradually thicker outwards. On slowly pressing the upper lens against the under one, a number of concentric coloured rings, having the point of contact of the lenses for their centre, appeared, and increased in size when the pressure was increased. These rings, or more properly systems of rings, are in this form of the experiment seven in number, and each of them is composed of a number (ranging from eight in the first or smallest ring to two in the outermost) of rings of different colours, the colours, though different in each of the systems of rings, preserving the same arrangement as the colours of the spectrum; thus, in the second ring the inside colour is violet, and the outside scarlet red. The colours are very distinct in the first three systems of rings, but become gradually confused and dull towards the outside, till they almost fade away in the seventh system. The centre is deep black. The thickness of the air-film at the centre is about half a millionth of an inch, and increases gradually to nearly $\frac{1}{100000}$ of an inch, when the colours disappear. See INTERFERENCE.

Newton, JOHN, the friend of Cowper, was born in London, 24th July (o.s.) 1725. He had little schooling, and, as his father was master of a trading ship, the boy joined him at eleven and sailed under him for six years. Next impressed on board a man-of-war, he was made midshipman, but was degraded and cruelly treated for an attempt to escape. He was allowed at Madeira to exchange into an African trader, joining a slaver at Sierra Leone, and sailed with her for two years, returning to England in 1747. He next sailed to Guinea and the West Indies as mate on a Liverpool slaver, married in 1750, and made several voyages of the same nature as master, giving his leisure to study. In 1755 he became tide-surveyor at Liverpool. In 1764 he was offered the curacy of Olney, and he was at once ordained deacon, and next year priest. Hither the poet Cowper came about four years later, and an extraordinary friendship quickly sprang up between the two men. Newton was a burning Calvinist, and his influence was to a great extent disadvantageous to the sensitive nature of the poet. Newton left Olney in 1779 to become rector of St Mary Woolnoth, London, and there he died 21st December 1807. Newton's prose-works, *Omicron* (1762), *Cardiphonia* (1781), &c., are now but little read, save his vigorous and interesting *Authentic Narrative of some Interesting and Remarkable Particulars in his own Life*. But his name can never be forgotten from his association with Cowper, and from some of his *Olney Hymns*, which have been taken to the heart by the English-speaking religious world.

Newton-Abbot, a Devonshire urban district, at the influx of the Lemon to the Teign estuary, 15 miles (by rail 20) S. of Exeter. Ford House, a good Tudor building, has lodged both Charles I. and William of Orange, who here in 1688 was first proclaimed king. The foundation-stone of the agricultural college was laid in 1912. Pop. 14,000.

Newton Heath, since 1890 one of the wards of the city of Manchester.

Newton-in-Makerfield (otherwise NEWTON-LE-WILLOWS and EARLSTOWN), a thriving town of Lancashire, 16 miles E. of Liverpool and 16 W. of Manchester. An important railway junction, it has rapidly increased in size, and large printing-works, bleach-works, iron-foundries, and a sugar-refinery are in operation, whilst numbers of hands

are employed in the making of railway wagons. Near to the town is a fine racecourse. At Park-side, $\frac{1}{2}$ mile distant, the Right Hon. W. Huskisson met with the accident which caused his death, on the occasion (15th September 1830) of the opening of the railway. Newton returned two members to parliament from 1558 to 1832, when it was disfranchised. Pop. (1801) 1455; (1881) 10,580; (1921) 18,796.

Newton-Stewart, one of the most beautifully situated among the smaller towns of Scotland, on the Wigtownshire side of the Cree, near its mouth. It owes its name to a son of the Earl of Galloway, who obtained a charter making it a burgh of barony in 1677. Pop. 1800.

Newtown (Welsh *Drefnewydd*; anc. *Llanfair Cedewain*), a manufacturing town of Montgomeryshire, North Wales, on the Severn and the Montgomery Canal, 13 miles SSW. of Welshpool. It is the centre of the Welsh flannel manufacture, and also produces tweeds, &c. Robert Owen was a native. Pop. (with Llanllwchaearn) 5700.

Newtownards, a town of County Down, 14 miles E. of Belfast by rail. Flax-spinning, muslin weaving, tapestry, and embroidering, cotton-printing, hemstitching, hosiery making, and nursery gardening are the industries, and there are important markets. Pop. 9600.

New Westminster, formerly the capital of British Columbia, on the north bank of the Fraser River, 10 miles from its mouth, is the centre and port of a fruit-growing, salmon-fishing, and lumbering district; pop. 15,000.

New-year's Day was celebrated by some religious observance, generally accompanied by festive rejoicing, among most of the ancient nations. The Egyptians, the Chinese, the Jews, the Romans, and the Mohammedans, although differing as to the time from which they reckoned the commencement of the year (see CALENDAR, CHRONOLOGY, YEAR), all regarded it as a day of special interest. On the establishment of Christianity the usage of a solemn inauguration of the New Year was retained; but considerable variety prevailed, both as to the time and as to the manner of its celebration. Christmas Day, the Annunciation (25th March), Easter Day, and 1st March have all, at different times or places, shared with the 1st of January the honour of opening the New Year; nor was it till 1751 that the 1st of January was accepted in England. It had long before been adopted by Scotland and other countries. The early Fathers—Chrysostom, Ambrose, Augustine, Peter Chrysologus, and others—in reprobation of the immoral and superstitious observances of the pagan festival, prohibited in Christian use all festive celebration; and, on the contrary, directed that the Christian year should be opened with a day of prayer, fasting, and humiliation. The festal character of the day, however, generally was preserved, though the day was also observed as a day of prayer.

From the earliest recorded celebration, we find notice of feasting and the interchange of presents as usages of New-year's Day. Suetonius alludes to the bringing of presents to the capital; and Tacitus makes a similar reference to the practice of giving and receiving New-year's gifts. This custom was continued by the Christian kingdoms into which the western empire was divided. In England we find many examples of it, even as a part of the public expenditure of the court, so far down as the reign of Charles II.; and, as all our antiquarian writers mention, the custom of interchanging presents was common in all classes of society. In England, as in Germany, this custom has been largely eclipsed by the still more popular practice of Christmas gifts (see CHRISTMAS); in Scotland, as in France and Italy, New-year's Day

is still the day most observed, and the festival according to Old Style, twelve days later, still lingers in corners of the country. In many countries the night of New-year's Eve, 'St Sylvester's Eve,' was celebrated with great festivity, which was prolonged till after twelve o'clock, when the New Year was ushered in with congratulations, complimentary visits, and mutual wishes for a happy New Year; this is an ancient Scottish custom (see HOGMANAY). In many places the practice of tolling bells till midnight, and then 'ringing in the New Year' is still observed. Many religious communions are wont to celebrate it with a special service or 'watch night.' In the Roman Catholic Church New-year's Day is a holiday of strict obligation. See Chambers's *Book of Days*.

New York, the 'empire state' of the American Union, is the twenty-ninth in area and the first in population. Lying between 45° and 40° 29' 40" N. lat., and 71° 51' and 79° 47' 25" W. long., and bordering on Ontario, Quebec, Vermont, Massachusetts, Connecticut, New Jersey, and Pennsylvania, it is somewhat triangular in shape. Its boundary line measures 1420 miles, of which 879 miles, or nearly two-thirds of the entire length, lie along the shores of Lake Erie, the Niagara River, Lake Ontario, the St Lawrence River, and Lake Champlain. The remaining portions of the boundary are formed by arbitrary straight lines. Area, 49,204 sq. m., or almost that of England. Long Island is the largest, and Manhattan, containing the most populous part of New York City, the most important of the many islands.

The surface structure of New York is remarkably diversified, and presents many contrasts of elevation. The state is traversed by numerous chains of mountains and hills, among which lie beautiful valleys. There is also much rolling land, and there are several extensive plains. The greatest elevations are in the eastern and north-eastern parts of the state, but nearly the whole of the south-eastern part is hilly or mountainous. From this highland region the land slopes gradually, and declines in a series of terraces, north and west toward Lake Ontario. The most level portions are those bordering that lake and the St Lawrence River. The mountainous region in the east is cut by the gap of the Mohawk River. The narrow valley of this stream, once traversed by a mighty river which drained the great Ontario basin, joins at right angles the deep depression in which are Lake Champlain, Lake George, and the Hudson River. Both of these valleys pass directly through the Appalachian system of mountains, and divide the state into three distinct sections. The mountains are also disposed in three groups. The Adirondacks (highest point, Mount Marcy, 5400 feet), in the north-eastern part of the state, are completely isolated by the valleys of Lake Champlain and the Mohawk River from all other parts of the Appalachian system. South of the Mohawk valley are the Catskills with various associated groups, such as the Helderberg and the Shawangunk Mountains, covering an area of about 500 sq. m. The Shawangunk Mountains are continuous with the Blue or Kittatinny Mountains of Pennsylvania. The Taconic range of New England enters the state still farther south, and passes south-westerly into New Jersey. This range is cut by the Hudson River, and forms the celebrated Highlands.

The geology of New York is peculiarly interesting and comprehensive. With the exception of the Jurassic formations and a few others closely related in time with the Jura-Trias, its rocks exhibit deposits of nearly every period, from the primitive Archæan rocks to the Tertiary and recent alluvium. Briefly and superficially classified, the outcropping rocks are disposed as follows: In the north-eastern

part of the state, with the Adirondacks as a centre, is a somewhat circular area of Archæan formation. Along the eastern side of the Hudson River and near its mouth, the Archæan rocks again appear, and are continuous with the primitive formations of New England. Nearly surrounding the Adirondack region is a belt of Silurian rocks, which extends southward along the western shore of the Hudson, and westward, bordering upon Lake Ontario and Lake Erie. North of the Adirondacks is a belt of Cambrian rocks, and south and west of the Silurian belt the greater part of the formation belongs to the Devonian age, with traces of Carboniferous deposits, but no true coal-measures. There are in the state some extensive iron-mines, deposits of lead, copper, zinc, and other valuable minerals, and an abundance of building-stones. The salt-springs, especially those of the Onondaga salt group, are of great value. There are also valuable petroleum springs, and mineral and medicinal springs—the most noted are those at Saratoga, Ballston, Sharon, Richfield, Avon, and New Lebanon.

The most important river belonging entirely to the state is the Hudson (q.v.). The Oswego, draining a chain of lakes in the central part of the state, the Black, and the Genesee are affluents of Lake Ontario; the St Lawrence forms part of the northern boundary; the Niagara connects Lakes Erie and Ontario, and the Delaware, the Susquehanna, and the Allegany rise within and drain the southern portions of the state.

New York lies mainly in the lake region of North America. The eastern part of Lake Erie, one-half of Lake Ontario, and one-half of Lake Champlain are controlled by the state. Among the numerous lakes of north-eastern New York, Lake George and the Adirondack lakes are the most noted. There are three groups of picturesque lakes in central New York. The mountains, rivers, and lakes of New York make it famous for its scenery. Of this, one of the most notable features is the number of waterfalls, among which the mighty Niagara is of course pre-eminent. Other beautiful falls are the Falls of the Genesee (q.v.), Trenton Falls, the Kaaterskill Falls in the Catskills, and those of Cohoes, Ticonderoga, and at Watkin's Glen.

The average temperature of New York is about 47° F., with a range of over 100°. The climate is thus subject to extremes, but is very healthful. Although the surface is so diversified, most of the soil is arable, and much of it is fertile. More than one-half the area of the state is under cultivation. The usual farm products are raised in abundance. In the lake valleys there are many vineyards. Hops and tobacco are also important crops. In the vicinity of New York and the other large cities market-gardening is a profitable occupation, and, indeed, New York leads the Union in the production of vegetables, though dairying is the most important type of farming, and the highland regions yield excellent milk, butter, and cheese. But manufacturing is the leading industry, and in the value of its manufactured products New York is the foremost state of the Union. Moreover, its geographical position and its natural avenues of communication with other parts of the country, together with the system of canals and railroads, make it the leading commercial state. There are several canals, of which the Erie (see CANAL) is the most important. New York is the centre towards which nearly all the great railroads of the country tend, and within the state there are about 14,000 miles of railway.

Previous to the coming of the whites the territory now known as New York was occupied by the Iroquois (q.v.) Indians. Almost simultaneously, in 1609, Samuel Champlain discovered the lake

which bears his name, and Henry Hudson explored the Hudson River as far as the present site of Albany. A few years later settlements were made by the Dutch, but they were looked upon as intruders by the English, who in 1664 forced them to surrender their city of New Amsterdam, which had grown up on Manhattan Island. The name was then changed to New York, and, with the exception of a short period in 1673, the city remained in the possession of the English till the war of the revolution. As in the other colonies, the early settlers endured many vicissitudes, and were at different times engaged in conflicts with the Indians. In the struggle for independence, in the war of 1812, and in the civil war New York played a prominent part. The physical structure of the state has made it a most important factor in the development of the nation, and in population, wealth, and political influence it has always held the pre-eminence.

With her great material prosperity New York has not neglected the education of her people. The whole range of public education (school and university) is under the Board of Regents of a body called the University of the State of New York. There is no more complete school-system in the country. It includes about 12,000 public schools, 1000 public high schools and academies, besides many private schools and academies; and there are nearly fifty colleges, universities, and schools of higher learning, not including theological seminaries and professional schools.

Politically the state is divided into sixty-two counties; it returns the largest number (43) of representatives to congress. No other state has so many large cities and thriving, enterprising towns. New York City is the centre of a thickly populated district, which is second only to London in the number of its people and the importance of its commercial interests. The other most important cities are Buffalo, Rochester, Syracuse, Albany (the capital), Yonkers, Utica, Schenectady, Troy, Binghamton, Niagara Falls, Elmira, Jamestown, Mount Vernon, Amsterdam, Poughkeepsie, Auburn, New Rochelle, Newburgh, Watertown, Kingston, Oswego, Cohoes, Rome, Gloversville, White Plains, Lockport, Olean. Pop. (1800) 589,051; (1850) 3,097,394; (1890) 5,997,853; (1900) 7,268,894; (1920) 10,385,227.

NEW YORK, CITY OF, officially so called since 4th May 1897, is the most important city on the American continent, and, next to London, the most populous in the world. It is situated on New York Bay at the junction of the Hudson, or North River, and the East River. It is divided into five boroughs: Manhattan, between the North, East, and Harlem rivers; the Bronx, on the mainland to the north, across the Harlem River; Richmond (Staten Island), to the south-west, across New York Bay; and on Long Island (to the south-east, separated from Manhattan by the East River), Queens, in the east, and Brooklyn, to the south-east. Comprised in the various boroughs there are several islands, such as Ward's, Randall's, and Blackwell's (renamed Welfare Island in 1921, the seat of the city and other hospitals) in the East River and in Hell Gate; and Governor's Island, Ellis (with an immigration station), and Bedloe's (with the Statue of Liberty) in New York harbour. The harbour, one of the finest in the world, consists of the outer harbour or Lower Bay (area, 88 sq. m.), separated from the Atlantic Ocean by Sandy Hook bar; and the inner harbour or Upper Bay (14 sq. m.), connected with the former by the Narrows, a strait 1 mile wide, between Long Island and Staten Island. There is a narrow channel, Kill van Kull, between Staten Island and the mainland, and a passage by Long Island Sound into Hell Gate and the Harlem and East rivers. The har-

bour's approach has fortifications at Sandy Hook and the Narrows, and the upper entrance to the East River is also guarded. Manhattan Island is $13\frac{1}{2}$ miles long, with an average breadth of $1\frac{1}{2}$ miles; and it is on this island that the larger proportion of New York's millions live, while here also is the main business district of the metropolis. In the south of Manhattan is Old New York, surrounding the Battery and Castle Green, and composed of many winding streets which are relics of the old settlements. North of Washington Square and 9th Street, Manhattan is laid out in an orderly arrangement of streets and avenues; the former run across the island from south-east to north-west, and are numbered up to 162d street; the latter run north-east and south-west, and are numbered from 1st to 12th Avenue, with four additional avenues numbered A, B, C, and D. Across Manhattan running roughly from south to north lies Broadway, to which, by reason of its being out of the regular alignment of streets and avenues, a special interest attaches. In its southern or downtown district, where it develops from the Battery, are to be found the City Hall, the building of the Sub-Treasury, Wall Street (the financial centre of the city, and in fact of the United States), and the various commercial houses. A little farther up-town, on the east side, is to be found the tenement district, one of the most crowded in the world. Then it develops into the shopping district, and thence into the residential flat district. The finest thoroughfare in New York City is 5th Avenue, stretching from Washington Square to Mount Morris Square, and in its course bordering Central Park on its east side. At its junction with Broadway and 25th Street stands one of the most original, as it was one of the first, of New York's skyscrapers, the 'Flatiron Building,' while on that portion facing Central Park are to be found the Metropolitan Museum of Art and many palaces of New York's millionaires. The most striking feature of the architecture of New York is the 'skyscraper,' made necessary by the very high cost of land, Manhattan, the heart of the city, having only a comparatively small area. The earliest of these giant buildings was the Singer, held at first to be impossible of construction, but proving on completion that the steel frame was the solution of New York's building problem. The Metropolitan Life Insurance Company building on the eastern flank of Madison Square, or 23d Street, has an imposing tower containing 50 stories above the sidewalk level, and reaches an altitude of 700 feet. This height is, however, exceeded by the gigantic Woolworth building, the tallest building in the world excepting the Eiffel Tower; it has 51 stories, and rises to an altitude of 792 feet. In the interests of public health and safety the vertical height of these buildings is now subject to regulation, a New York Building Resolution of 1924 determining that the height of all buildings subsequently to be erected should bear a certain relation to street width, withdrawal of a whole or a part of any building from the street-line making permissible, however, a proportionate increase in height; the resolution regulated also the area of yards, courts, and other open spaces, and controlled, too, the location of trades and industries. Among many other prominent buildings in New York are the Public Library, the Astor Library, Columbia University and Library, the Museum of Natural History, the Treasury building, Bankers' Trust, Equitable, Whitehall, and General U. S. Grant's tomb on Riverside Drive. Riverside Drive faces the Hudson River, and, built on reclaimed land, is one of the finest residential streets in the world. Morningside Heights in the north of Manhattan is the highest point of the island, and here is the very

fine Protestant Episcopal Cathedral Church of St John the Divine, begun in 1892 and expected to be finished about 1934. Of New York's many other churches the most prominent are the Catholic Cathedral of St Patrick; Trinity, St Paul's, St Thomas's (all Protestant Episcopal); Fifth Avenue Presbyterian; St Mark's-in-the-Bowwerie (Dutch Reformed); Church of St Paul the Apostle (Paulist Fathers). There are also notable Baptist and Methodist churches, and Jewish synagogues and temples. New York's hotels are legion, and include the Pennsylvania (the largest in the world), the Commodore, Waldorf-Astoria, Plaza, Biltmore, Ambassador, St Regis, Ritz-Carlton, while the Old Holland House has been converted into office buildings. New York suffers under the disadvantage of having within the city only two of the termini of the railways which serve her, the others being on the New Jersey side of the Hudson. Grand Central Station at Park Avenue and 43d Street was entirely reorganised in 1922, and is now a wonderful structure, with underground shopping centres, and hotels and offices built overhead. Pennsylvania Station is also a wonderful erection. New York is saved much of the smoke nuisance by the fact that within a radius of 30 miles only electric locomotives may be used. Along the shores of the Hudson River, both on the Manhattan and New Jersey shores, lie the great docks, capable of taking the largest vessels in the world. Thousands of river boats keep up communication between New York and New Jersey with its railway termini, while there is an ever-increasing number of tunnels under the Hudson (one for vehicular traffic was commenced in 1920), as also under the East River. The East River is spanned by many fine bridges, the Brooklyn Suspension, Manhattan, Williamsburg, Queensboro, New East River, Hell Gate, and 3d Avenue bridges being the most important (see BRIDGE). On Manhattan Island itself, and in the other boroughs of New York, transport is by means of tramways, overhead railways, and subways of the most elaborate description. Traffic tends continuously and rapidly to increase, and despite a great extension of transport facilities the provision of an adequate system of passenger conveyance remains a problem constantly demanding solution.

The Battery Green encloses 21 acres, planted with trees, shrubbery, and grass, and occupies the most southern point of Manhattan Island; it marks the original site of Nieu Amsterdam. After the American Revolution it was used for military and civic displays, and from that time until near the middle of the 19th century was the fashionable promenade. On its west side is Castle Garden (q.v.). The laying-out of Central Park was begun in 1857. The park comprises 843 acres, extends from 59th to 110th Street, and is bounded by 5th and 8th Avenues. Its dimensions are thus $2\frac{1}{2}$ miles by $\frac{3}{4}$ mile. It is well laid out, and contains lakes (The Lake, The Mere, &c.), woods, walks, drive-ways, bridle-paths, recreative and garden structures, and some fine monuments—e.g. the Egyptian obelisk brought from Alexandria in 1880. Here also are situated the Croton Reservoir and two receiving reservoirs. Other parks in New York are Riverside, Morningside, Mount Morris, Madison, Union, and Washington, all situated on Manhattan Island; Van Cortlandt and Pelham Bay in the Bronx; Dyker Beach and Highland in Brooklyn; and Forest and Silver Lake in Queens and Richmond respectively. The New York Botanical Garden occupies a reservation of nearly 400 acres in Bronx Park north of Pelham Parkway, and the Zoological Park (Bronx Zoo), opened in 1899, has served as a model for other parts of the world. Coney Island in Brooklyn is a favourite and famous

amusement place. The theatres of New York City are many and well built. The most outstanding are the Metropolitan Opera House, Manhattan Opera House, Hippodrome, Capitol, Casino, Booth, Century, Knickerbocker, Republican. Notable clubs are the Union, Union League, Century Association, Knickerbocker, Players', University, Manhattan, Metropolitan. Restaurants and dance halls and cinema houses are without number but too ephemeral for individual note.

New York City now ranks as the first shipping port of the world. As the commercial metropolis of the United States, its foreign commerce comprises more than half the total export and import trade of the Union. Its domestic commerce is also of great dimensions, many places all over the Union drawing their supplies from it. Its manufactures are hardly of less importance. The principal industries include printing and publishing, lard and sugar refining, meat-packing, and the making of furniture, clothing, machinery, textiles, musical instruments, and iron and steel goods.

New York is governed by a mayor, elected for four years, five borough presidents, also elected for four years, and a board of aldermen consisting of a president, elected for four years, and sixty-five members elected for two years. Finance is under a separate controller elected for four years by the city, but the mayor chooses all the other officials. When Tammany (see TAMMANY SOCIETY) ruled there was much graft and many scandals.

New York is perhaps the most cosmopolitan city in the world, the emigrants of all countries entering and forming separate colonies, such as Greek Colony, Little Italy, Chinatown, and Hebrew, Russian, and Negro quarters. This last is increasing enormously, and has driven the white inhabitants out of whole blocks in the middle-class districts of the city.

The water-supply of New York was formerly provided almost wholly by Croton River and its lakes, situated some 40 miles from the city. But with the growth of population the system which had been in use from 1842 proved altogether inadequate, and in 1917 a new scheme was put into operation. By it a supply of water estimated at 300 million gallons a day was brought from the Ashokan reservoir in the Catskill Mountains. The total distance from the Ashokan to Richmond borough is 120 miles, and the undertaking was second only to the Panamá Canal in magnitude. Even this added supply did not prove sufficient, and as part of the Catskill system it was soon found necessary to tap the Schoharie watershed. New York's various sources of water-supply are estimated to be capable of providing over 1000 million gallons daily. The Catskill water enters New York through a siphon under the Hudson River. The chief reservoirs on the system apart from Ashokan, are Kensico, Hill View, and Silver Lake.

New York contains numerous institutions for higher education. Among the chief are Columbia University, New York University, the College of the City of New York, Fordham University, Union Theological Seminary, the College of Physicians and Surgeons. The principal libraries in New York are New York Public Library (formed in 1895 by consolidation of the Astor and Lenox libraries and the Tilden Trust; see LIBRARY), the library of Columbia University, the Morgan Library (q.v.), and the Metropolitan Museum of Art Library. The Metropolitan Museum, housed in magnificent quarters to the east of Central Park facing 5th Avenue, is a treasure-house of the fine and decorative arts. The exhibits, some of which are unique and are of great value, range in date from 3000 B.C. to the present day. The American Museum of Natural History is also notable.

John Verrazani, a Florentine navigator, was the

first European who entered New York bay, in 1525. His exploration was interrupted by a storm that compelled him to put to sea without making a settlement. In 1609 Henry Hudson entered Hudson River, and, trading with the aborigines, ascended the stream for about a hundred miles. In 1614 the Dutch built a fort on Manhattan Island, and in 1623 a permanent settlement was made, named Nieu Amsterdam. Brooklyn, first settled in 1636, was organised by the Dutch governor of New Amsterdam in 1646, and named Breukelen, after a place 8 miles NW. of Utrecht. In 1664 the English drove out the Dutch from New Amsterdam; in 1673 the Dutch the English. In 1674 Manhattan Island came permanently by treaty into the possession of Great Britain, the name New York being given in honour of James, Duke of York. New York privateering was a great business during the climax of the slave importation, about 1730-35. At the time of the American Revolution the city's population was less than that of Philadelphia and Boston. It was evacuated by the forces of Great Britain in 1783, and from 1785 to 1789 was the seat of government of the United States. In 1774 the city census, taken by government, showed a population of 22,861; (1800) 60,489; (1825) 166,136; (1850) 550,394; (1860) 813,669; (1870) 942,292; (1880) 1,206,599; (1890) 1,515,301, a recounting by the city police giving 1,710,715. In 1898 Brooklyn, Richmond County, Flushing, Port Hempstead, Jamaica, Long Island City, Newton, Jamaica Bay, East and West Chester, and Pelham were incorporated with the municipality; and 'Greater New York,' with an area of 309 square miles, had a population of 3,437,202 in 1900, of 4,766,883 in 1910, and of 5,620,048 in 1920.

Wilson, *New York: Old and New* (2 vols. 1902; new ed. 1909); Theodore Roosevelt, *New York* (1891; new ed. 1903); Valentine's *Manuals of the Corporation of the City of New York* (old series, 1841-70, ed. D. T. Valentine; new series, 1916 *et seq.*, ed. H. C. Brown); M. J. Lamb, *History of the City of New York* (1877; new ed. 1910); Leslin, *History of the Greater New York* (1898); F. B. Kelley, *Historical Guide to the City of New York* (1913); histories by Lossing (2 vols. 1884) and Stone (1872); popular works by Goodwin, *et al.* (2 vols. 1899) and by Hemstreet (1899 to 1903); and as a guide book, *Rider's New York City* (1924 edition, ed. F. T. Cooper).

New Zealand.—The British Dominion of New Zealand consists of two large islands, called simply North and South, and of a number of small islands and islets. Of the latter, some lie in tropical Polynesia where the Cook group and Niue, Penrhyn, and Suvarrow islands have been annexed to the Dominion. The last two are held on account of their fine lagoon harbours. New Zealand also governs most of the Samoan Archipelago under a mandate from the League of Nations. Under another mandate she shares with Great Britain and Australia the administration of the phosphate-bearing island of Nauru. Finally, the uninhabitable antarctic territory of Ross Land has been placed under her Governor-general. Of the islands other than North and South, only Stewart and the Chathams are of much value. They support together about a thousand inhabitants, and might easily be made to carry more. Cook Strait, narrowing to 13 miles, separates North from South Island, and is known as 'the wind-pipe of the Pacific,' owing to the north-westerly gales that sweep through it. Foveaux Strait, 15 miles across, divides South from Stewart Island. Broadly speaking, North and South Islands comprise all that is important of New Zealand as well as all but a few hundred square miles of its area, which, apart from the tropic islets, is stated to be 103,656 sq. m., lying between latitudes 34° 22' and 47° 18' S. lat., and between 166° 27' and 178° 34' E. long.

The Dominion is, therefore, one of the most isolated of civilised countries of any size. Twelve hundred miles of the unbroken Tasman Sea separate it from Australia to the west and north-west, and a slightly larger breadth of South Pacific Ocean divides it from the nearest Polynesian group. South America is more than 4000 miles to the east, and southward there are but a few islets between it and the ice-fields of the Antarctic. Very few islands indeed break the immense expanse of the ocean surrounding New Zealand.

The archipelago itself, however, atones for its loneliness. It is lofty, picturesque, fertile, healthy, and with natural features full of variety and interest. Of these the most striking are long, lofty ranges and high volcanic cones. Everywhere ridges or summits stand out, usually near at hand. More than a hundred and fifty peaks or cones exceed seven thousand feet, and in the South Island sixteen rise to a height of more than ten thousand. In the south-west of that island much of the spine of the Southern Alps passes above the level of eternal snow, reaching its acme in Ao-rangi (Mount Cook), 12,349 feet. Next come Tasman 11,467 feet, and Dampier 11,287 feet. Near the north-eastern coast again, in the double range of the Kaikouras, Tapuaenuku attains to 9460 and Kaitearau to 8700 feet. In the North Island the ranges are lower, seldom exceeding 5000 feet. Four volcanic cones, however—Ruapehu 9175, Egmont 8260, Ngauruhoe 7515, and Tongariro 6458—equal the finest of the southern mountains in beauty. Mountains cover the larger part of the South Island, running in close parallel chains from south-west to north-east. They present an unbroken barrier along the whole west coast, and, spreading across to the east coast of the northern provinces of the island, show a formidable wall in the seaward Kaikouras. In consequence, the small mining settlements on the west coast are completely cut off from the more populous middle east, south-east, and south, and the same is true of the agricultural and grazing communities of Nelson and Marlborough at the northern end of the same island. There is virtually no communication by land between the last-named districts and the progressive provinces of Canterbury and Otago. A long coach road through river gorges and narrow valleys unites Nelson with the western coal-bearing districts of Westport and Greymouth and the gold-mines of Westland. A railway lately opened through Arthur's Pass and the beautiful Otira gorge now links Canterbury with the same districts. South of the Otira only an occasional mountain-climber ever passes from east to west. The one practicable pass in that region, the Haast, though less than a thousand feet high, is unused, as the south-west littoral, south of Martin's Bay, is an uninhabited sanctuary reserved for the native flora and fauna, and for imported game such as the moose and the wapiti. There the fiords or sounds, nineteen in number, are visited in summer by steamships conveying throngs of tourists to gaze on scenes where the richness of the vegetation and the height of the precipitous cliffs and mountains rival or surpass the scenery of Norway or the coast of Alaska.

In the North Island the mountain chains, though (as said) lower, show the same chief feature—ranges running from south-west to north-east, from Cook's Strait to East Cape on the Bay of Plenty. These chains—the Rimutaka and Tararua to the south, farther north the Ruahine, Kaimanawa, and Raukumara—likewise impede communication between eastern and western settlements. They have been penetrated by a railway through the gorge of the Manawatu River uniting Wellington with Napier. Farther south another railroad

climbs from Port Nicholson over the Rimutaka, and, passing through the inland plain of the Wairarapa into the province of Hawkes Bay, links up with the line from the Manawatu. In the northern half of the island—the province of Auckland—there is no continuous dividing spine, though there are many considerable elevations. Fairly in the centre of the island rises a cluster of massive volcanic heights, some active, some dormant. One of the latter, Tarawera, broke out in June 1885, in the worst natural convulsion recorded in New Zealand, destroying the famous Pink and White Terraces, and killing more than one hundred persons. Volcanic activity is still to be witnessed at numerous points between Mount Ruapehu and White Island, an active island-cone in the Bay of Plenty, in a region covering nearly 6000 sq. m. The centre of the disturbing forces seem to be near the oval Lake Rotorua. Hot springs, sometimes boiling, warm pools, solfataras, and mud volcanoes are to be seen in numbers, and the medicinal powers of the acid or alkaline waters are utilised in a state sanatorium frequented by patients suffering from rheumatic, neurotic, or skin diseases. Earthquakes are experienced in many parts of both islands.

Lake Taupo (238 sq. m.), in the volcanic district, is the largest body of fresh water in the Dominion. Some 40 miles north-east of it lie several smaller lakes, noted for a beauty that also distinguishes Lake Waikare to the east. In the South Island many alpine lakes, notably Manapouri, Te Anau, Wakatipu, and Rotorua, take high rank for scenic grandeur, and Kanieri and Mapourika in Westland for softer loveliness. Several lakes have great potentialities as providers of electric power, and two, Waikare and Coleridge, are already being used on a considerable scale.

For the same purpose the rivers promise to be of much service. In the South Island they have more or less the character of mountain torrents, too swift and variable in volume to be of any real use for navigation. The largest, the Clutha, 260 miles long, discharges over 2,000,000 cubic feet of water per minute into the sea, but, like most New Zealand rivers, is bar-bound. The lower elevation of the North Island allows certain rivers a slower current and more even depth. The Waikato, 220 miles long, the Wanganui, 140 miles, the Mokau, and Waihou are navigable for considerable stretches by steamers of light draught. The sea-borne coastal traffic of the islands is naturally considerable. The harbours, though numerous, are not all well placed for trade. The admirable shelter afforded by the sounds is quite useless for mercantile purposes, and to the north of them almost every harbour on the west coast is bar-bound. This is notably the case with that fine sheet of water the Kaipara, fed by navigable rivers. In a number of cases harbour works have been required to fit ports for commerce. Fortunately three of the four largest trading ports in the country—Auckland, Wellington, and Lyttelton—have wide, deep entrances.

The mountainous surface of the western half and of the north-eastern corner of the South Island has had, of course, a marked effect on settlement. Of half a million inhabitants, less than 30,000 live west of the Alps, and four-fifths of the whole are found between the Kaikouras and the Waiau to the west of Southland. In this tract are found the large Canterbury plains and many smaller levels, as well as rolling downs and arable valleys. The North Island, though without any very extensive plain, has a greater share of fertile, practicable country, and this, with its milder climate, has attracted for many years a greater influx of settlers. The south-eastern portion of Wellington province, the pumice-covered plateau round Lake Taupo and

over the Kaingaroa Plains, and the scrub or fern-clad clay lands north of Auckland, are the least inviting parts. Otherwise, except on the heights of the central spine, the North Island is almost everywhere attractive to settlers.

Geology.—The classification and distribution of the pre-Cretaceous formations of New Zealand are still matters of dispute. Over wide areas the rocks of these formations have not yet yielded fossils, and problems of correlation are rendered especially difficult by widespread metamorphism. The gneisses, granulites, and plutonic rocks which occur in the south-west of Otago and in Stewart Island are usually regarded as Archæan. From Fiordland to Cook Strait a series of crystalline schists and other metamorphic and igneous rocks form the core of the main divide in the South Island. They are separated from the Archæan gneisses by a wide area of unaltered sediments which pass into the crystalline schists by gradual transitions, and rocks of similar character can be traced as a broad belt along the south-east side of the main divide all the way to Cook Strait, and thence into the North Island, where they form the chief mountain chain (the Ruahine Range). Similar rocks appear again in the core of the north-east promontory of North Island. The above complex of sedimentary, igneous, and metamorphic rocks is known to include strata of Ordovician, Siluro-Devonian, Permo-Carboniferous, and Trias-Jurassic age. Quartz veins in this series carry gold and scheelite.

After the deposition of the Jurassic came a period of great orogenic movements, which resulted in intense folding and fracturing of all the pre-Cretaceous strata, the strike of the folds and the main faults running in a north-east and south-west direction, and determining the trend of the coast-lines and the chief mountain chains. Widespread regional metamorphic effects were produced at the same time, and the movements were accompanied by the intrusion of plutonic rocks ranging in composition from acid granites to ultra basic peridotites, such as the well-known dunite or olivine rock of Mount Dun. The great movement of uplift was followed by a period of denudation and depression, during which were deposited strata of Cretaceous and Tertiary age. This younger series of rocks contains valuable coal-seams at several horizons. There is evidence of volcanic action during the Cretaceous period; but the greatest outburst of volcanicity in New Zealand began in early Tertiary times, and resulted in extensive accumulation of lavas and tuffs, particularly in North Island, where volcanic activity has not yet ceased. Towards the close of the Tertiary period New Zealand underwent a movement of uplift, which reached a maximum in South Island. The elevation was accompanied by noteworthy block faulting, which has influenced considerably the topography of the islands. The uplift resulted, too, in a marked increase of glaciation in the South Island. A movement of depression followed, carrying the land slightly below its present level, and this in turn was followed by slight elevation, evidence of which can be read in the raised beaches which fringe the coast. Study of a geological map of New Zealand shows that no inconsiderable part of the islands is covered by Pleistocene and Recent deposits, and these are noteworthy for the occurrence in them of abundant remains of the Moas and other extinct birds, some of which were contemporary with man.

Climate.—The islands are fortunate in a climate temperate, very healthy, and, for the most part, pleasant. It is, however, marked by very great variety, due chiefly to the length of the archipelago from north to south, to the conformation of the mountain ranges, and to fresh and sometimes

stormy oceanic winds. Northward of the Hauraki Gulf and the Lower Waikato conditions are more or less sub-tropical, though the ocean breezes and plentiful rainfall save the summer from being oppressive. At the colder end of the South Island the climate does not differ much from that of southern England and Ireland. As in England, the west coast is wetter than the eastern; indeed, the contrast is considerably greater, and is often very marked between localities not far apart. The western coast of Stewart Island, for example, is made almost uninhabitable by the violent south-west gales. The eastern side is mild, and, though damp, is quiet and agreeable. Over the greater part of the islands rain-bringing winds blow mainly from the south-west and north-west, and where the moisture of the north-west winds is caught by the spinal ranges, the country eastward is comparatively dry. The province of Auckland is an exception, for there the north-east wind often brings with it clouds heavy with rain, whereas farther south that wind is usually dry. Napier, on the east coast of the North Island, with an average rainfall of about 33 inches, has at least 20 inches less rain than Taranaki on the opposite coast, where, over much of the dairy-farming country, grass remains green all the year round. The most remarkable contrast, however, between east and west is exhibited by Christchurch and Hokitika, about half-way down the South Island. The average rainfall at Christchurch is between 25 and 26 inches per annum, while that of Hokitika is about 116 inches. Hokitika nevertheless enjoys 1871 hours of sunshine a year, with a very clear atmosphere when rain is not actually falling.

Wellington, the capital, the climate of which may be called a mean for the inhabited parts of the Dominion, has an average rainfall of nearly 49 inches, with rather more than 2100 hours of sunshine. Its mean temperature is about 5 degrees warmer than that of London. The mean temperature of Auckland city is about 9 degrees warmer than that of London, while those of Dunedin and Invercargill in the South Island are almost the same as that of the English metropolis. New Zealand, then, shows a combination of a plentiful rainfall with an ample share of sunshine, due to the absence of fogs and light drizzle. Certain districts are windy, notably Wellington city, the mountain gorges of the Southern Alps, and the country for some miles outside their mouths. Blizzards and cyclones, however, are virtually unknown. Snow falls heavily on the mountains, but is a curiosity on the coasts of the North Island, and on the west coast everywhere. The islands are entirely free from malaria. The pleasantest climate is perhaps that on the east coast of the North Island, from Napier northward to the Coromandel Peninsula, also round Nelson and Blenheim on the southern side of Cook Strait, and in Banks Peninsula. The greatest summer heat is commonly felt near the mid-east coast of the South Island, between the Kaikouras and the district of Oamaru. Here more than 90° is often registered, and droughts sometimes occur, though not sufficiently protracted to ruin farmers or destroy live-stock. Apart from the alpine heights, the only intolerable climate is to be found on the mountainous south-west of the South Island, where rainfall often approaches 200 inches, and a considerable tract of country is uninhabited. In the interior of central Otago dry heat in summer and severe cold in winter are common. In the Southern Alps snowstorms are known heavy enough to cause costly losses of sheep. The redeeming features of the sub-alpine climate are the clear, bracing air and the sunshine, which is usually plentiful even in winter.

SOUTH ISLAND

P A C I F I C

Population.—The estimated white population at the end of 1924 was 1,316,000. To this must be added about 53,000 Maori. At the date of annexation in 1840 the country did not contain more than two or three thousand whites. By 1855 this number had risen to 37,000. The following table shows the progressive decennial increase from 1861 on :

Year.	Population.
1861.....	99,021
1871.....	256,393
1881.....	489,933
1891.....	626,658
1901.....	772,719
1911.....	1,008,468
1921.....	1,239,980

The increase has, of course, been largely due to immigration. In the sixty years 1861–1920 the total gain from this cause was 483,480, and the gain still continues, partly because the government still assists certain classes of emigrants, such as agricultural labourers, both boys and adults, female domestic servants, and persons nominated by friends in the colony. The excess of males over females in the islands, once proportionately very large, is now quite small, and may be expected to disappear. Ninety-eight per cent. of the population are of British birth or extraction. The largest element is the English, the Scottish coming next with about 24 per cent. of the total, and the Catholic Irish third, with about 13 per cent. The chief European foreign elements are Scandinavians and Yugoslavians, the latter almost entirely concentrated on the kauri-gum fields north of Auckland. Chinese number about 2200, and are kept in check by a poll-tax and other restrictions, and by the fact that they have but two or three hundred women with them, and usually return to China after saving a few hundred pounds. The only other Asiatics are about 1200 British Indians, known as 'Syrians.' In the North Island a large majority of the population is settled within 30 miles of the coasts, and the emptiest tracts are in the spinal ranges and the country to the east and west of Lake Taupo.

In March 1923 the North Island contained 772,000, the South 500,000 people. Of the four chief towns, Auckland now contains about 180,000, Wellington and Christchurch each about 115,000, and Dunedin about 78,000. In all cases liberal expanses of suburb are included. The fifth town, Wanganui, has but 25,000 inhabitants. Throughout the islands rural population only very slightly exceeds urban.

The Maori.—When British traders, whalers, and sealers began to establish themselves on the New Zealand coasts in the first four decades of the 19th century the islands were sparsely occupied by a brown race calling themselves Maori, in number probably between 100,000 and 150,000. Very large tracts of forest and mountain—including most of the South Island—were empty of human life. The Maori were Eastern Polynesians, whose point of departure was most likely the Cook Islands, whence in large double-canoes they contrived to run to New Zealand before the prevalent north-east winds. They settled down, dispersed in small village communities, linked to some tribal organisation, and placed chiefly by bays, rivers, lakes, or the edges of forests where fish and birds could be found. They found virtually no four-footed beasts in the country, few food-plants except the edible fern, and brought with them only a black rat, now rare, and a small dog, now extinct; also two vegetables, the taro and the sweet potato. They were tillers of the soil, without flocks or herds, and their tribes and sub-tribes were incessantly at war. Without metals or pottery their tools and weapons were those of the Neolithic stage, and they used neither

the bow nor the boomerang. Yet their *pa*, or stockades, showed engineering skill, and they were no mean adepts at building huts and canoes and in carving, and weaving hemp fibre. The patterns on their cloaks and tattooed faces were artistic, and they spoke a very pure dialect of the liquid, resonant Eastern Polynesian. In height and colour they resemble the swarthier peasants of Greece or Spain. Their features are rather Caucasian than Asiatic or Negroid, but the mouth, though not blubber-lipped, is coarser than the European, and their bodies are longer in proportion and the skull more pyramidal. The quality of their intelligence is good, and not confined to a few exceptional males. This, with their courage, eloquence, courtesy, sense of humour, and fondness for sport, has won for them a respect seldom rendered by British settlers to a barbaric race. Throughout most of the 19th century their numbers rapidly declined owing to the use of the musket in tribal wars and to diseases and unhealthy habits resulting from their first intercourse with whites. After 1890, however, they began to increase slowly but steadily as the spread of education among them led them to obey medical advice and adopt more sanitary methods of living. Tuberculosis is still rather common among them. Including half-castes they now number about 60,000. Most of them have at least a strain of white blood. Since 1872 there have been no rebellions or serious riots, and they may now be reckoned peaceable, loyal, and contented. They possess full citizenship, and send four representatives to the elective House of Parliament, while two of their chiefs sit by custom in the Nominated Upper Chamber, and the Ministry usually contains one Maori member. Though they have sold most of their tribal lands to the government, they still retain about 4,650,000 acres, mostly fertile, and in the aggregate very valuable. Considerable tracts of this are leased to whites, commonly under the supervision of official trustees, who protect the Maori from fraud and imposition. The remainder is farmed by the natives, who are gradually using it to better advantage, and already own about 500,000 sheep, with many cattle, horses, and pigs. The state provides them with free education, in special schools in which English is compulsory. They may and do, however, use ordinary schools also. Nearly all of them now speak and write English. They still talk Polynesian among themselves, but dress in European fashion, and may fairly be termed civilised. Crime is rare among them, and drunkenness not a scourge. They understand the value of money, but seldom engage in trade, and rarely work for wages, except for short periods on farms. For the most part they live on their own land in communal villages, are at least nominally Christians, and on good terms with their white neighbours. Almost the only remaining mark of racial repugnance is the objection of white women to marry Maori males. Regular marriages between male whites and Maori women are fairly common, and it seems likely that the smaller race will thus gradually be absorbed by the larger.

Land Settlement and Tenure.—Of a total area of 66,292,000 acres, 43,653,000 acres in the islands were officially returned as occupied in 1923. This, however, does not include land held by the Maori communes. The one-third of the islands still unoccupied is mostly mountainous or covered by lakes or forest. About 4,000,000 acres are admitted to be unfit for settlement. Of occupied soil 21,000,000 acres are held in freehold, and 18,000,000 leased from the Crown. New Zealand is far from being a land of peasant farmers; nearly 18,000,000 acres of the occupied land is in holdings of more than 1000 acres each, nearly $3\frac{1}{2}$ millions more in

holdings of between 640 and 1000 acres. The larger properties are almost all pastoral, and used for raising wool, mutton, and beef. The smaller are mainly dairy farms in the North Island. In the south, however, there is much mixed farming, including cereal growing, horse-breeding, and the rearing of high-class sheep and cattle. Grazing rather than tillage is predominant. Grazing, however, has involved the laying down of more than 16,000,000 acres in artificial grasses, chiefly those used by English farmers, as their carrying power is several times greater than that of native grasses. Besides land 'improved' in this or other ways, 25,000,000 acres of the occupied land are classed as 'unimproved,' and remain chiefly under native grasses. The area under grain and root crops is about 1½ million acres.

Grazing, then, is the chief source of production, and sheep and cattle of wealth. The number of sheep was estimated at about 24,000,000 in 1895. The sheep are mainly cross-bred, the basis being Merino crossed with Romney Marsh, Lincoln, Leicester, or Southdown. The prime object is to produce carcasses suitable for freezing combined with a heavy fleece. The average weight of the fleeces is now 7·72 lb. Inspection and grading of meat at the freezing factories is carried out with the utmost care. Cattle numbered 3½ millions in 1923, and, thanks to the growth of dairying, had increased through several decades. Much keenness is being shown both officially and by societies to improve the breed and yield of the dairy cows. Milking machines and the use of electric power are cheapening production. The butter and cheese are made in factories, mostly co-operative, of which there are 535, producing 11,182,000 cwt. of butter and 1,268,000 cwt. of cheese. The state encourages those factories by loans and otherwise, but their inspection is minute. Auckland, Taranaki, and Southland are the chief dairying districts. Beef and bacon are exported, but the total weight produced in the islands is comparatively small. Horses number 330,000, and the quality is high. Bee-keeping is coming into favour.

Agriculture.—The climate and soil of the eastern lowlands are well suited to cereals, but for many years the production of these has tended to dwindle. The annual consumption of wheat is no more than 7½ million bushels; yet though the Dominion was a generation ago a substantial exporter, it has lately had to import from Australia for home use. Similarly the export of oats, once over 10,000,000 bushels, is now very small, the crop having fallen by two-thirds. About half a million of bushels of maize are grown, and rather more barley. In 1922-23 no less than 493,000 acres were in turnips for live-stock; mangolds, potatoes, peas, and beans are grown. About 73,000 acres are devoted to growing grass for seed, and large crops of hay and lucerne are raised. The area in orchard is about 31,000 acres, making progress especially in Nelson, Central Otago, and Northern Auckland. In the last-named district, citrus fruits, notably lemons, can be grown profitably. Apples are an article of export to London. Grapes, from Hawkes Bay northwards, can be grown out-of-doors with commercial success.

The Department and Board of Agriculture are extremely active in educative and experimental work by means of visiting instructors and experimental farms. Inspection and supervision are carried to great lengths, but the results have been admittedly beneficial, and the standard of farming, particularly in all matters connected with grazing and dairying, has steadily risen during the last generation. Under recent acts of parliament, boards of control for frozen meat and for dairy produce have been set up to regulate export and

marketing, especially in Great Britain. This, it is claimed, has stabilised prices and reduced exporters' costs; but the experiment is new. A forestry department encourages planting, and about 100,000 acres are now in plantations, largely of exotic pines. The reserves of native forest are admittedly insufficient, and the export of timber may have to be stopped.

Mining.—Many minerals of economic value are found, but only three have been mined on a large scale—gold, coal, and kauri-gum. Important gold discoveries were first made in 1861, and the total export since 1853 is valued at over £91,000,000. The annual product has shrunk to between £500,000 and £600,000, and there is little expectation of increase. Silver is extracted from the gold bullion in the Auckland mines. The value of the total production of coal is estimated at about £34,000,000. Except that supplied to steamers, all is consumed locally. The yearly output is no larger than it was in 1909. There is very little anthracite, but a good supply of excellent bituminous, and very large quantities of brown coal. Two state collieries are profitably worked. Kauri-gum, the fossil resin of ancient pine forests, is found in large subterranean deposits in the northern part of Auckland. When cleaned and scraped it is shipped, chiefly to London, for use in making varnishes and linoleum. The annual value is above £500,000, but the supply is not inexhaustible. Very large deposits of iron ore and iron-sand have been examined, and an attempt is now being made to work the first-named commercially. Cinnabar, sulphur, tungsten ore, and phosphates are mined on a small scale. The islands are well provided with building-stone, including marble and decorative serpentine, and with fireclay.

Trade.—The overseas trade is large, though almost entirely carried within the empire. The one important exception is trade with the United States, which in 1922 exceeded £8,000,000, but with a heavy balance against New Zealand. Trade with Germany is increasing. Nearly two-thirds of the whole commerce is with Great Britain, which in 1923 took £37,000,000 of New Zealand produce, selling the Dominion in return about £24,000,000, mainly manufactured articles. The total trade reached £101,000,000 in the year 1924. The exports in that year were above £52,000,000, and, per head of population, were believed to be the highest of any country. New Zealand being a debtor community should export about £7,000,000 more than she takes in. Her transit trade is small. An overwhelming proportion of her exports—92 per cent.—are of pastoral products. By comparison the exports of minerals and agricultural produce are low: taken together they come to about 5 per cent. of the whole, and the export of wholly manufactured goods is also trifling. The trade figures have, of course, been swollen by inflated prices since 1914. Still, they were large before—£45,275,000 in 1913—having risen to that amount from £15,070,000 in 1893. Between 1883 and 1893 they were almost stationary. In the Empire, outside the United Kingdom, New Zealand does a considerable, though fluctuating, trade with Australia and Canada, and a substantial business with India and the Pacific Islands. The principal imports are spirits and wines, tobacco, cottons and silks, tea, sugar, and other groceries, machinery (including heavy imports of motors and parts thereof), clothing of all kinds, books, and chemicals. The revenue collected in customs-duties is equal to rather more than one-sixth of the declared value of the imports. Excise duties are levied on beer and tobacco. The distillation of spirits is forbidden. Sugar, imported from Fiji, is refined at Auckland.

Manufactures.—Manufacturing for export in

New Zealand consists almost entirely in the partial preparation of goods and raw materials for the wholesale market. They come chiefly under the heads of meat freezing and preserving, butter and cheese making, milk-condensing, wool-scouring, tanning and fellmongering, and flax-milling. The principal manufactures for local consumption are those of timber and furniture, engineering (including motors), woollen milling, boot and shoe making, clothing, printing and bookbinding. The value of the product of all 'principal industries' may be estimated at about £70,000,000, and the number of employees at 70,000, as against 8700 engaged in mining. Only about one-sixth are females. Factory inspection is closely carried out, and the wages and conditions are almost all regulated by awards and registered agreements under the Industrial Arbitration Act. The woollen and leathern articles bear an excellent name.

Banking and Insurance.—The banking business is carried on by six banks of issue, four of which are well-known Australian banks; and the other two, the Bank of New Zealand and National Bank of New Zealand, are established under special local acts. The first of these two is largely a state institution, as the government holds a third of its paid-up capital, and nominates its chairman, auditor, and a majority of its directors. This interesting arrangement appears to work successfully, as the bank does much the largest banking business in the country. Savings-banks held in March 1924 as much as £51,300,000 of deposits. Life insurance is carried on by eleven companies and a government life insurance office. The latter, and the Australian Mutual Provident Society, both do business on a very large scale. The government also does a considerable business in fire insurance, and it is claimed that its competition has reduced rates by 10 per cent. No less than forty-one fire insurance offices carry on business in the Dominion. Friendly societies—chiefly Oddfellows, Foresters, and Druids—have £2,600,000 in funds, and an average capital per member of £32.

History.—Abel Jansen Tasman, the first European to discover New Zealand, coasted along its western shores in December 1642. Captain Cook, the next navigator to behold it, landed in 1769. During the first forty years of the 19th century some hundreds of British subjects—traders, whalers, sealers, and missionaries—gradually settled in the islands, and obtained considerable influence over the natives. The British government, however, was very unwilling to annex the country. It had disavowed Captain Cook's action in taking possession of it in the name of George III., and was only driven to annex the archipelago in 1840 by the disclosure of a French plan to colonise it. An English company, moreover, founded by Edward Gibbon Wakefield, had begun systematic settlement by despatching a band of emigrants to be established at Port Nicholson, now Wellington. Captain Hobson, R.N., was therefore authorised to annex New Zealand. He landed in the Bay of Islands, 29th January 1840, and by the Treaty of Waitangi, concluded with the principal Maori chiefs a few weeks afterwards, obtained their allegiance at the price of guaranteeing them the fee-simple of all their unsold lands. In consequence, the whole country now occupied by whites—save an area of about 2,400,000 acres confiscated during war—has had to be purchased from the tribes. For thirteen years the colony was governed despotically by imperial administrators, one of whom, Sir George Grey, showed marked ability. By proclamation in January 1853 the colonists were granted self-government. Until 1871 progress was checked in the North Island by expensive intermittent struggles with Maori tribes, in which

the natives, though sometimes successful, were finally crushed by the colonial militia. Meanwhile the rapid development of sheep-farming and gold-mining in the South Island had stimulated settlement there. External trade, £900,000 in 1853, had increased to over £12,000,000 in 1873. In the seventies, Sir Julius Vogel initiated a policy of raising loans for railways and telegraphs, land purchase, and immigration. He also abolished the large provincial councils, which had hitherto divided control with the central government, and established such institutions as a public trust office, state life insurance, and a state land transfer system (that of Torrens). New Zealanders thus became habituated to a large measure of governmentalism. Until the end of 1890, however, the colony's affairs were still in the hands of the larger landowners, banks, and professional and commercial classes. In the year named these were ousted by a combination of the smaller farmers and trade unionists, headed by Liberal and Protectionist politicians. The result was a series of experimental laws which attracted critical interest outside the islands. Of these, those enacting progressive taxation, female franchise, compulsory arbitration in labour disputes, old age pensions, loans for farmers and for house-building, repurchase and subdivision of large estates, rating of ground values, and many others of less interest are still in operation. But those enacting local option and the perpetual leasing of state lands have been abandoned, the former in favour of a triennial poll on national prohibition, the latter in favour of sales of crown lands in freehold. This last, it is alleged, has encouraged much disastrous speculation and helped the rise of land values to fictitious heights, land for dairying fetching, in some instances, more than £100 an acre in 1919–20. The Liberal-Labour alliance broke up shortly after the death of the popular leader, Richard Seddon, in 1906. Seddon had supported the Imperialist fiscal policy of Joseph Chamberlain, and had grafted a preference to British imports on to the protectionist customs tariff of the colony. In 1912 the more conservative party, self-styled 'Reform,' gained office, and its leader, Mr W. F. Massey, remained premier till 1925, though during the Great War he headed a coalition government, styled 'National.' Since 1919 New Zealand politics have been made difficult by the divisions of three parties, the largest of which, 'Reform,' barely holds its ground between the other two, Liberal and Labour. Public life is largely a battle between two powerful classes, the agrarians and the trade unionists, both of which are well organised. Recent laws of interest are those which endeavour to control and direct the important exports of meat, butter, and cheese. New Zealand sent ten contingents of mounted riflemen to fight in the Boer War, while her effort in the Great War was on a much larger scale. At a cost of over £82,000,000 she equipped and sent overseas more than 100,000 men, and her soldiers bore themselves more than creditably in Palestine, the Thracian Chersonese, France, and Flanders: 16,700 of them died in service, and while they lost but 354 prisoners, they captured over 19,000, with more than 200 cannon. After the war their government spent about £26,000,000 in settling some thousands of returned soldiers as farmers.

The Crown is represented in New Zealand by a Governor-general appointed by the Imperial Government, but paid by the Dominion, and is governed by two Houses of Parliament. Of these the members of the Upper (Legislative Council) are nominated for seven years by the Governor-general-in-Council, and are paid £350. The Lower (House of Representatives) is elected triennially by uni-

versal adult suffrage without any plural voting. It consists of 80 European and 4 Maori members, paid £450 a year. The Ministry now number 12. Local government is carried on by several hundred municipalities, county councils, road boards, harbour boards, hospital and charitable aid boards. Local indebtedness amounts to about £32,000,000. The Colony, proclaimed a Dominion in 1907, is represented in London by a High Commissioner, and has trade or business agents elsewhere in the Empire and in the United States.

Defence.—A small permanent body of staff officers, instructors, artillery and ordnance officials, form a nucleus round which a territorial division is organised, numbering when mobilised 12,500 officers and men. Three brigades of mounted riflemen are included. The naval force consists of a warship largely officered and manned from England, and a training-ship.

Education.—Public education was so imperfect during the first thirty years after annexation that the proportion of scholars to population was less than 10 per cent. in 1867. It is now about 17 per cent. Primary education is almost entirely controlled by the Department of Education in conjunction with nine provincial boards and numerous school committees. Only one-eleventh of the schools are private. The curriculum of the public schools is modern and fairly liberal. It is secular, but includes moral as well as physical instruction. School teachers, of whom one-third are males, have to take the oath of allegiance. Secondary schools instruct 20,000 students, one-fifth of whom are technical. The university of New Zealand is an examining body with a senate, and four colleges are affiliated to it, one in each of the chief towns. Each manages its own affairs, and though government grants are given to higher education, the university is independent of state control. It has established schools of mining, engineering, medicine, agriculture, commerce, and law, and counts about 4000 students, rather more than one-fourth being women. A good many New Zealanders, however, still resort to British universities and hospitals. Public expenditure on education now exceeds £3,000,000 annually. The number of native children receiving instruction is extremely creditable to the Maori race.

Justice.—The Higher Courts are the Supreme Court, with a Chief-Justice and ten Puisne Judges, and a Court of Appeal. From the latter, leave may be granted to appeal to the Imperial Privy Council. Smaller cases, civil and criminal, are dealt with by Resident Magistrates, with jurisdiction up to £200, and by Justices of the Peace (jurisdiction up to £20). On the whole, legal procedure is cheap and expeditious. Barristers may practise as solicitors and *vice versa*. The number of divorce petitions in 1922 was 644.

Public Health.—Thanks to climate, a high standard of comfort and sanitation and also medical inspection, the population is extremely healthy, with a very low death-rate. The birth-rate is not high. It fell in the twenty years from 1903 to 1923 from 26.6 to 21.95; in 1919, indeed, it was 21.42, that, however, being due to the absence of males during the war. The death-rate in the same years fell from 10.40 to 9.3. In the year of the influenza epidemic, 1918, it rose to 14.84. The percentage of deaths of children under one year to each thousand births is 47, and is, therefore, much the lowest rate in the world. Especial care is taken to preserve infant life. Hospitals and lunatic asylums are state institutions. The Public Health Act gives wide statutory powers. The influenza, which killed 6700 whites and Maori in 1918, is much the most deadly epidemic that has ever swept the islands.

Public Finance.—The average revenue during the five years ending with March 1924 has been about £29,000,000, the average expenditure about £2,000,000 less. The chief sources of revenue are customs, land and income tax, railways, post and telegraphs, stamps, and excise. Taxation has become heavy since the Great War, and is about £12 per head. The net public debt is about £215,000,000, of which somewhat more than one-third is war debt. The remainder is for outlay on railways and other works, and on loans to farmers and work-people, to the latter for housing. War debt apart, the outlay may be called directly or indirectly remunerative. The return on the railways is 3.82 per cent. The state is still a very large landowner.

Pensions.—Pensions paid by the government amount to a sum of more than 2½ million annually. They are classed as Old Age, Widows', Military, War, Miners', and Epidemic. The military, war, and epidemic (influenza) pensions are falling in number, the old age and widows' are increasing. Male old age pensioners must be at least sixty-five, female sixty years of age, unless they have children under fourteen. They must be 'sober and respectable,' and be British subjects and not Asiatics. A widow must have at least one child under fourteen. A National Provident Fund administered by a Government Board provides benefits for voluntary contributors.

Nexø, MARTIN ANDERSEN, Danish novelist, was born in 1869 in a poor quarter of Copenhagen, and spent his boyhood in Bornholm near Nexø (whence his name). From shoemaking and bricklaying he turned to books and teaching, and in 1906 won European fame with *Pelle the Conqueror* (trans. 1915-17; 4 parts), describing poor life from within and the growth of the labour movement.

Next of Kin. See KIN (NEXT OF).

Ney, MICHEL, French marshal, was born at Saarlouis, 10th January 1769. A non-commissioned officer in a hussar regiment when the Revolution began, he quickly secured promotion under the new order of things, becoming successively Kléber's adjutant-general at the blockade of Mainz in 1794, and in 1796 general of brigade. For the capture of Mannheim by a daring *coup de main* he was made a general of division in 1799. He was interim commander of the Army of the Rhine for a time. After the peace of Lunéville Bonaparte brought about his marriage with Aglaé Louise Auguié de Lescans, a young friend of Hortense Beauharnais, and appointed him inspector-general of cavalry. On the establishment of the empire he was made marshal of France. In 1805 he stormed the entrenchments of Elchingen, for which he was created Duke of Elchingen. He distinguished himself anew at Jena and Eylau, and his conduct at Friedland earned him the title from Napoleon of 'le brave des braves,' and the grand-eagle of the

Legion of Honour. He next served in Spain, but quarrelled with his superior Masséna about the plan of the campaign and returned to France, where he remained inactive till in 1812 he received the command of the third corps in the Grand Army. He covered himself with glory at Smolensk and Borodino (q.v.), and was rewarded with the title of Prince of the Moskwa. He led the rear-guard in the disastrous retreat, and his sleepless vigilance alone saved the remnant of the Grand Army. In 1813 he opened the battle of Lützen, and showed his usual capacity and courage at Bautzen, but was defeated by Bülow at Dennewitz. He fought heroically throughout the fatal struggle at Leipzig, and was also in the last defensive campaign of 1814; but after the capture of Paris he urged the emperor to abdicate, and submitted to Louis XVIII., who loaded him with favours. On Napoleon's return from Elba Ney was sent against him at the head of 4000 men; but the old enthusiasm proved too much for him, and with most of his soldiers he went over to his old master's side. In the final campaign he commanded the first and second corps, opposed Brunswick at Quatrebras (June 16), and led the centre with more than bravery at Waterloo; twice—once at the head of the cavalry, last with the Old Guard—he strove to break the English force in vain. During the day he had five horses shot under him. After the capitulation of Paris he yielded to the entreaties of his family to set out for Switzerland; but a costly Egyptian sabre, the gift of Napoleon, led to his being suspected by an official, and arrested near Aurillac. He was condemned to death for high-treason, and was shot in the garden of the Luxembourg on 7th December 1815—a cruel act of revenge that might well have been spared the bravest among the sons of France. Even the cost of the prosecution was extorted from his unhappy widow.

His son published his (uncompleted) *Mémoires* (1833). See *Lives* by Welschinger (Paris, 1893), Bonnal (1910 *et seq.*), and Hilliard Atteridge (1913).

Nez Percés, a tribe of American Indians, settled in Idaho, on the Lapwai River. The Nez Percés 'proper' have always been loyal to the whites, and have made good progress in civilisation. But in 1877 the treaty reductions of their reservation led to a sanguinary outbreak on the part of the 'non-treaty' Nez Percés, who murdered settlers, fought the soldiers, and then fled across Idaho, Montana, and Dakota. They were overtaken and beaten, and the survivors (some 350) transferred to Indian Territory; but in 1885 some were restored to Idaho, and the rest joined the Colville Indians, in Washington. There is no evidence that they ever had a custom which would justify their name, 'pierced nose.'

Ngami, LAKE, a shrunken lake of the Bechuanaland Protectorate, situated at the northern extremity of the Kalahari Desert, in 20° 30' S. lat. and 23° E. long., at an altitude of 2810 feet. When discovered by Livingstone in 1849, it was a lake of about 50 miles long by 10 to 20 miles broad, its chief tributary being the Kubango. It is now little more than a reed-grown swamp in the dry season—the southern end of the Okavango swamps.

Niagara ('Thunder of Waters'), a river of North America, forms part of the boundary between New York state and the province of Ontario. It flows from Lake Erie to Lake Ontario, a course of 36 miles, during which it makes a total descent of 326 feet—about 50 feet in the rapids immediately above the great falls, and nearly 110 feet in the seven miles of rapids below. It encloses several islands, the largest Grand Island, which is nearly 10 miles long. Four miles below this island

are the most famous falls in the world. The centre of the river here is occupied by Goat Island, dividing the cataract into two—the Horseshoe (Canadian) Fall, with a descent of 158 feet, and the American fall, 162 to 169 feet; the outline of the former is about 2640 feet, of the latter 1000 feet. The volume of water which sweeps over this immense chasm (nearly nine-tenths passing over the Canadian fall) is about 15,000,000 cubic feet a minute. The depth of water on the crest of the falls is less than 4 feet, except in a few places, notably at the apex of the Horseshoe Fall, where it is about 20 feet. The limestone edge of both falls is rapidly wearing away in the centre; the Canadian fall now presents the form of a V; in the American fall the same tendency is visible, although the process has begun much more recently. For seven miles below the falls (to the point, that is, where it has been supposed that the falls originally stood) the river is shut in between perpendicular walls of rock, from 200 to 350 feet high. For some distance below the falls there is still water, the body of water which pours over the precipice sinking, and only coming to the surface again two miles below, where the whirlpool rapids begin; a little lower is the whirlpool, where a sharp turn sends the waters hurling against the Canadian side, and then sweeping round in a great eddy before they find a vent at a right angle with their former course. The lands bordering the river on both sides of the falls are state parks. On 4th October 1890, the first sod was cut of a tunnel for utilising the water-power of the falls, regarded as one of the greatest engineering enterprises ever undertaken. By the middle of 1895 the first transmission of electric power for commercial purposes had been made, 4000 horsepower having been transmitted to an aluminium manufactory a mile distant. Power is now transmitted for hundreds of miles, and is also used in the immediate neighbourhood (see NIAGARA FALLS).

Niagara Falls, two cities on the Niagara, 2 miles below the Falls, one (pop. 50,000) is New York State, the other formerly called Clifton (pop. 15,000), in Ontario. They are tourist centres, and have many factories using power from the falls. Three great steel bridges connect the railways and roads of the United States and Canada.

Niam-niam, an African people dwelling along the watershed that parts the feeders of the Bahr el-Ghazal from those of the Welle-Makua and other northern tributaries of the Congo. Of the negroid Nuba stock (with Nilotic admixture), they have round faces, broad heads, bodies long in proportion to the legs, and are inclined to corpulency. They have no cattle. Considerable manual and artistic skill is shown in the forging of iron, making of pottery and baskets, and the carving of wood. They are passionately fond of music, and play a kind of mandolin. To these people legends of 'tailed men' are referable.

Nias, an island to the west of Sumatra, Dutch since 1857, has an area of about 1800 sq. m. The surface is mountainous, the highest peak rising 2000 feet. The Niassers are of the Malay race, but fairer than the Malays usually are. They are gentle, sober, and peaceful, remarkably ingenious in handicraft. They grow rice, coconuts, bananas, tobacco, sugar-cane, and pepper.

Nibelungenlied, also called *DER NIBELUNGE NÔT*, an old German epic poem, that takes rank next after the Homeric poems amongst the great epics of the world. The original substratum of the work is undoubtedly the saga of Sigurd, recounted in the Elder Edda; it is from that source the epic derives its mythological elements, and in all probability the tragic conception of an all-

compelling destiny which dominates the action of the poem. To this original substratum must be added two others—one taken from the legendary history that grew up out of the migrations of the peoples, especially the struggle between the Huns and the Burgundians; the other embodying the spirit, the sentiment, the life and circumstances of the crowning age of chivalry, the middle of the 12th to the middle of the 13th century, during which period the poem, as we now have it, was unquestionably written. Who was its author, or rather the man who cast it in its present form, is altogether unknown; the attribution of it to the minnesinger of Kürnberg in Upper Austria now finds very little acceptance. The oldest elements of the work must have been long current in the form of popular songs or versified sagas; but the incidents of the story as recounted in the epic seem to have been fused into a unity some time previous to the 12th century. The existing version is due to one who was steeped in the ideas of the courtly poetry of the middle ages; the writer took the story that had in process of time grown together into a connected epic narrative, and impressed upon it his own methods of poetic vision, and his own peculiar versification—in short, his own style. German commentators are of opinion that the writer worked from originals composed in Latin. After the Reformation all interest in the poem quite died out, and was only revived in the end of the 18th century. But it was not until twenty years and more of the 19th century had passed that German students began to be aware of the inestimable literary treasure they possessed in the *Nibelungenlied*. A keen discussion arose as to its unity; one school, headed by Lachmann, maintained that it was merely a collection of folk-songs, loosely strung together, or rather intermingled one with another; an opposing school defended the unity of the narrative and of the poem.

The tale is briefly this. Sigfried, the son of the king of the Netherlands, has become the possessor of the storied treasure of the Nibelungs, which carries with it the curse of dire evil to its owner. Sigfried marries Kriemhild, sister of Gunther, king of Worms, and then helps Gunther to win to wife Brunhild of Iceland, by taking Gunther's place without her knowledge and overcoming her in three trials of bodily skill and strength. After some years a bitter dispute breaks out between the heroines as to whether Gunther or Sigfried is the greater. Brunhild's jealousy is so great that she induces Hagen, one of Gunther's vassals, to murder Sigfried. Kriemhild, though she mourns long years for her husband, at length marries Etzel (Attila), king of the Huns. After Sigfried's death she had become the possessor of the Nibelungs' treasure; but Hagen had wrested it from her and sunk it at the bottom of the Rhine. At the end of several years Kriemhild, who still mourns for Sigfried, and still nourishes the desire for revenge upon Hagen and Gunther, invites her brother and his court to visit her. They do so, accompanied by a body of 11,000 knights and men-at-arms. The conclusion of the epic relates the bloody incidents attendant upon the total annihilation of the Burgundians at the court of Etzel, and the slaughter they made amongst their foes. There is a continuation of the poem, called the *Nibelungenklage*, or Lament for the Nibelungs, a production in every way much inferior to the *Nibelungenlied*. In spite of the uncouth versification of this last, it exercises a strong fascination upon the reader, owing to the grandeur of its conception, its strong characterisation, its earnestness and tragic intensity.

There exist numerous old MSS. of the poem; but the most valuable are three, called respectively the Munich,

St Gall, and Lassberg MSS., all of the 13th century. The best modern High German versions are those by Simrock, Bartsch, and L. Freytag. There are English translations by Lettsom (1850), Foster-Barham, Birch, and A. S. Way (1912). See Carlyle's *Miscellanies* (vol. iii.). See also WAGNER.

Nicæa, or NICE, a city of ancient Bithynia, in Asia Minor, situated on the eastern shore of Lake Ascania. It was built by Antigonus, the son of Philip (316 B.C.), and received the name of Antigonæia, which Lysimachus changed to Nicæa, in honour of his wife. It was a handsome town, and of great importance in the time of the Roman and Byzantine emperors. It is famous in ecclesiastical history for two Councils held in it, the First and Seventh Ecumenical Councils. The First Council of Nice was held 325 A.D., and was convened by the Emperor Constantine, for the purpose of defining the questions raised in the Arian controversy (see ARIUS, ATHANASIUS); the Nicene Creed adopted is discussed at CREED. The Council also deliberated on the Meletian Schism; and its decree on the celebration of Easter met with universal acceptance.—The Second Council assembled under the Empress Irene (787), for the purpose of reconsidering the subject of Images (see IMAGE-WORSHIP).

Nicaragua, a state of Central America, stretching right across the isthmus north of Costa Rica. An irregular square, the east (Caribbean) coast measuring 290 miles and the west coast 185, Nicaragua has an area of about 50,000 sq. m. The Central American Cordilleras form the backbone of the country; they run north-west and south-east at a distance of 12 to 30 miles from the Pacific, and attain elevations of 4000 and 5000 feet above sea-level. On the west the surface sinks rapidly to a longitudinal depression (110 feet), the southern two-thirds of which are filled by the large lakes of Nicaragua (115 miles long, 45 broad, and 140 feet deep in most parts) and Managua (35 miles long, 20 broad, 30 feet deep), the latter lying north of the former and 25 feet higher. This depression is studded with a chain of volcanic cones, standing on islands in the lakes (Ometepe and Madera, 4190 feet), and clustering thickly between the northern end of Lake Managua and the Gulf of Fonseca at the north-western extremity of the country, as Coseguina (3835 feet), which was the scene of a tremendous outbreak, lasting over four days, in 1835, Viejo (6267), Telica (4200), Momotombo (6890), Mombacho (4600), and several others. Though most of these are quiescent, some of them burst forth in eruption from time to time. Another low range separates this depression from the Pacific. The districts west of the central backbone are the chief seats of the population. There stand the towns Managua (the capital), León, Granada, Chinandega, Rivas.

East of the Cordilleras the surface falls away gradually; the spurs that break off from the main ridge sink into the low alluvial plains that face the Caribbean Sea. Thick forests clothe extensive areas on this side. A few of the eastward rivers are of good length, such as the Coco or Wanks (350 miles long), the northern boundary; the San Juan (125 miles), which drains Lake Nicaragua and separates Nicaragua from Costa Rica on the south; the Bluefields and the Rio Grande (230 miles). The low coast-belt, formerly called the Mosquito Coast (now the department of Bluefields) is lined with salt lagoons—Pearl lagoon having an area of 200 sq. m., and Bluefields lagoon half as much. The mountain-spurs east of the main chain are rich in minerals; gold is mined a little, as well as silver; coal, copper, tin, iron, lead, zinc, antimony, quicksilver, marble, &c. exist. As a rule the climate varies between 70° and 90° F., and there is a dry season

lasting from about December to May. The natural products of the soil are accordingly tropical. The forest trees include mahogany, rosewood, logwood, fustic, sandalwood, india-rubber, and numerous others that yield fancy woods, medicinal products, gums, and dyes. Large herds of cattle are bred and reared on the extensive plains of the centre and east. The rich soil of the cultivated western region yields maize (the staple food of the people), coffee, cocoa, sugar, cotton, rice, tobacco, indigo, and a great variety of tropical fruits. The east grows bananas, coconuts, and sugar. The exports are chiefly coffee, sugar, bananas, timber, and hides. The animal life is like that of Guatemala (q.v.). The population in 1920 was 638,000. The state religion is Roman Catholic, but all creeds are tolerated. The educational standard is low, in spite of universities at León, Granada, and Managua. The country is governed by a president (elected for four years), a legislative assembly, and a senate; both these bodies are elected by the people, the former for four, the latter for six years. There are 175 miles of railway, connecting the chief towns with Corinto.

Nicaragua, like the states north of it, was a centre of Aztec civilisation; but the Aztecs were preceded by another race, likewise civilised, who have left stone sculptures and monumental remains. The Aztec influence survives in archaeological ruins and relics and in the Indian dialects. Columbus sailed along the Mosquito Coast in 1502. Twenty years later the country was overrun by the Spaniards under Gil Gonzalez D'Avila, and in 1524 the city of Granada was founded. This town soon developed as the head of a stream of commerce that flowed up and down the San Juan River. In 1610 was founded León, the democratic rival of the aristocratic Granada. During the Spanish supremacy (after 1550) Nicaragua was a province of Guatemala. In 1821 it asserted its independence, and two years later joined the federation of the Central American states, a connection that lasted sixteen years. The history of the country after the severance from Spain is a record of war and dissension, war with Costa Rica, with Guatemala, and with Great Britain (1848), which had asserted a protectorate over the Mosquito Coast since 1655. This region was given up to Nicaragua in 1860. Between 1855 and 1860 the aristocratic and the democratic party were fighting tooth and nail, the latter being assisted by the adventurer William Walker (q.v.). Since then the chief events have been wars with her neighbours, resistance to attempts at confederation, and canal negotiations. Nicaragua has made laudable efforts to develop her resources and to advance along the path of civilisation, and she has given one name to literature—Rubén Darío (q.v.).

See Squier, *Nicaragua* (1852); Belt, *Naturalist in Nicaragua* (1873); Bodham-Whetham, *Across Central America* (1877); Lévy, *Notas Geográficas y Económicas sobre Nicaragua* (Paris, 1873); Bancroft, *History of Pacific States: Central America* (1882); and Joyce, *Central American Archaeology* (1916).

Nicaragua Ship-canal. The plan of cutting a canal through Central America by way of the San Juan River and Lake Nicaragua is by no means new. But the project was not taken up in earnest until 1884, when a treaty with this object in view was signed between the United States and Nicaragua. The Nicaragua Canal Company was formed early in 1889, and operations were begun at Greytown, but by 1893 the company ceased working from financial embarrassment. Several United States Commissions reported in favour of the scheme, but the senate insisted on a waiting policy. The rival Panamá scheme was adopted in 1903, consummated in 1914. However, the right

to construct a Nicaragua canal was conferred on the United States in 1916.

Niccola Pisano. See PISANO.

Niccolo da Foligno. See ALUNNO.

Nice (Ital. *Nizza*), chief town of the department of the Alpes Maritimes, France, stands on a beautiful well-sheltered site on the coast, 140 miles E. by N. of Marseilles and 110 SW. of Genoa. It has for many long years been celebrated as a winter-resort for invalids. The mean temperature of winter is 49° F., of summer 72°. Frosts occur but seldom. Pop. (1872) 42,363; (1886) 65,053; (1911) 98,865; (1921) 155,839. The city consists of three parts—the New Town on the west, the Old Town, and the Port on the east. The first of these is the part frequented by foreigners, particularly English (whence its name of 'English town'). Beautiful promenades stretch along the seashore, and are overlooked by villas and hotels. Numerous bridges across the little river Paglione (Paillon) connect the New Town with the Old or Upper Town. This part, with narrow streets, clusters at the foot of a rocky height, the Castle Hill; on the other (east) side of this hill is the harbour. The Castle Hill is an isolated mass of limestone 318 feet high, crowned by a strong castle, now in ruins, and is laid out in public gardens. The chief public buildings are the cathedral, the Gothic church of Notre Dame, the natural history museum, art gallery, library, observatory, casino, &c. The people manufacture olive oil, artistic pottery, and perfumery, grow flowers and southern fruits, the last of which they preserve, and produce inlay work in olive-wood. Most of these things are exported, chiefly by way of Genoa and Marseilles. The ancient Ligurian town of Nicæa, founded by a colony of Phœceans from Massalia (Marseilles), became subject to Rome in the 2d century B.C. It was in the hands of the Saracens during the greater part of the 10th century. Then, after existing as an independent city, it acknowledged the supremacy of the Counts of Provence and the House of Savoy (1388). In 1543 it was taken and pillaged by the Turks under Barbarossa. From 1600 onwards it was repeatedly taken by the French; and they kept possession of it from 1792 to 1814. In 1860 it was ceded to France by Sardinia. Masséna was born near to the city, and Garibaldi in it.

Nice. See NICÆA.

Nicholas, the name of five popes and an anti-pope. **NICHOLAS I.** was born of a noble Roman family, and was elected as successor to Benedict III. in 858. He showed great persistence in his endeavours to assert the supremacy of the Roman curia, especially in his successful disputes with Archbishop Johannes of Ravenna, Archbishop Hincmar of Rheims, and the patriarch Photius of Constantinople. His latest triumph was the restoration to her rights of Thietberga, the unjustly divorced wife of the Emperor Ludwig's younger brother, Lothaire, king of Lorraine. A synod of Metz in 862 had allowed the king to put her away and marry his mistress, but the pope reversed the judgment and deposed the too compliant Archbishops of Cologne and Treves. Nicholas died in 868.—**NICHOLAS V.** was originally called Thomas Parentucelli. Born at Pisa in 1398, he was educated at Florence and Bologna, and was named Bishop of Bologna by Eugenius IV. He showed such astuteness during the troubles of the Councils of Basel and Florence that he was chosen to succeed Eugenius IV. in 1447. He prevailed on the antipope, Felix V., to abdicate, and thus restored the peace of the church in 1449. He was a liberal patron of scholars, and despatched agents both to the East and West, to purchase or to copy important Greek and Latin manuscripts. The number collected is said to have

exceeded 5000. He remodelled, and may almost be said to have founded, the Vatican Library. He invited to Rome the most eminent scholars of the world, and extended his especial patronage to those Greeks whom the troubles of their native country drove to seek a new home in the West. He endeavoured to arouse the Christian princes of Europe to the duty of succouring their brethren of the East; but the age of enthusiasm was past, and he was forced to look on inactive at the fall of Constantinople in 1453. Nicholas died in 1455. He must not be confounded with an antipope of the same name, Peter de Corbario, who was set up, in 1328, by Ludwig of Bavaria, in antagonism to John XXII. (q.v.). See also NICOLAS (St.).

Nicholas I., emperor of Russia, was the third son of Paul I., and was born at St Petersburg, 7th July 1796. On 13th July 1817 he married the eldest daughter of Frederick-William III. of Prussia—a union that long affected European politics. Owing to the resignation of his elder brother Constantine, he succeeded to the throne on the death of Alexander I. (December 1825). A long-prepared military conspiracy broke out immediately after his accession, which he suppressed with great vigour and cruelty. After a brief ebullition of reforming zeal, he reverted to the ancient policy of the tsars—absolute despotism, supported by mere military power. A war with Persia commenced, was concluded by the peace of Turkmanshai (1828), which gave a considerable extent of territory to Russia. In the same year he entered upon a war with Turkey, in which victory, though at enormous cost, constantly attended his arms, and the peace of Adrianople obtained for Russia another increase of territory. The political movements of 1830, in the west of Europe, were followed by a national rising of the Poles, suppressed after a desolating contest of nine months, in which the utmost efforts of the whole military resources of Russia were required. Nicholas punished the rebellion by converting the kingdom of Poland into a mere Russian province, and strove to extinguish the Polish nationality. This policy, however, was viewed with great dissatisfaction throughout Europe, and the vanquished Poles were everywhere regarded with general sympathy. Russia, by Nicholas's mode of government, became more and more separated from the fellowship of the western nations. Intellectual activity was, as far as possible, restrained to things merely practical, education limited to preparation for the public service, the press was placed under the strictest censorship, and every means used to bring the whole mind of the nation under official guidance. His Pan Slavism also prompted him to Russianise all the inhabitants of the empire, and to convert Roman Catholics and Protestants to the Russian Church, of which the tsar was the head. War was waged against the mountaineers of the Caucasus with the greatest energy and perseverance, at the cost of immense sacrifices both of money and lives. The extension of British influence in central Asia was also viewed by him with alarm, and led to an unsuccessful expedition to Khiva. During the political storm of 1848-49 he abstained from interference until an opportunity was found in the request of the emperor of Austria for his assistance to quell the Hungarian insurrection. He succeeded at the same time in drawing closer the bonds of alliance between the Russian and Prussian monarchies. The re-establishment of the French empire still further tended to confirm these alliances, and led Nicholas to think that the time had at length come for carrying into effect the hereditary Russian scheme for the absorption of Turkey; but the unexpected opposition of Britain and France, and his own invincible repugnance to

yield led to the Crimean War (q.v.). He died 2d March 1855. See books by T. Schiemann.

Nicholas II., last emperor of Russia, was born 18th May 1868, and succeeded his father Alexander III. in 1894. Himself narrow-minded, he repeatedly allowed himself to be dominated by his bigoted and reactionary wife Alexandra Feodorovna (Princess Alix of Hesse), who in turn was under the influence of Rasputin and other charlatans and adventurers. Events of his reign include the great Kishinev pogroms conducted by the 'Black Hundred,' the tsar's initiation of the peace conference at the Hague (see PEACE AND INTERNATIONAL ARBITRATION), the disastrous war with Japan, the revolution of 1905, the granting of a constitution, afterwards as near as could be brought to nought, the tightening of the alliance with France, Russia's participation in the Great War, and finally the revolution of 1917. He was forced to abdicate in March, was sent to Tsarskoe Selo (Detskoe Selo), to Tobolsk, and to Ekaterinburg (Sverdlovsk), where on Koltchak's advance the local soviet caused him to be shot along with his wife, son, and four daughters, 16th July 1918.

Nicholas, Russian Grand Duke (born 1856), nephew of Alexander II., was commander-in-chief against Germany and Austria, August 1914 to September 1915, and governor-general in the Caucasus 1915-17.

Nicholas II. Land, a mountainous volcanic land with glaciers, N. of Cape Chelyuskin, discovered in 1913 by Vilkitiski, who explored its NE. coast to 81° N. lat., 96° E. long.

Nichols, a family of printers and antiquaries, associated with the *Gentleman's Magazine* from 1778 to 1856. To it belonged John Nichols (1745-1826); his son, John Bowyer Nichols (1779-1863); and his son, John Gough Nichols (1806-73).

Nichols, ROBERT MALISE BOWYER, poet, born 1893, son of John Bowyer Buchanan Nichols (b. 1859, himself a poet), was educated at Winchester and Trinity College, Oxford. After serving in the Great War, he was appointed to the chair of English Literature in the Imperial University, Tokio. His first book of poems, *Invocation*, was issued in 1915; *Ardours and Endurances* appeared in 1917, *Aurelia* in 1920, *Guilty Souls*, a drama, in 1922, and *Fantastica* in 1923.

Nicholson, JOHN, a distinguished Indian soldier, was born at Lisburn, 11th December 1822. In 1838 he joined the East India Company's service, and in 1840 his regiment was ordered to Ghazni in Afghanistan (q.v.), where, two years later, it was compelled to surrender to the enemy. After a time of miserable captivity he regained his liberty. On the breaking out of the Sikh war in 1845 he served in the campaign on the Sutlej, and was present at the battle of Ferozeshah. He was now appointed assistant to the resident at the conquered capital, Lahore. During the Sikh rebellion of 1848 he greatly distinguished himself, the preservation of the important fortress of Attock being due to his daring and promptitude, whilst soon after, at the Margulla Pass, he succeeded in intercepting and defeating a large body of the insurgents. At the battles of Chillianwalla and Gujrat successively he earned the special approval of Lord Gough, to whom he was immediately attached. The Punjab having finally become a British province, Captain Nicholson was appointed a deputy-commissioner under the Lahore Board. His success in bringing the savage tribes under thorough subjection to law and order was something marvellous.

In the mutiny in 1857 Nicholson perhaps did more than any other single man to hold firm the British grasp of the Punjab. He it was who suggested the formation of the famous movable column, and he

presided over its organisation; while in his dealings with the suspected regiments of sepoys he exhibited throughout a brilliant combination of boldness with subtlety, discretion, and astuteness. At Trimmoo Ghaut on the 12th and 14th July he nearly annihilated a force of rebels, and at Najafgarh on the 24th he dispersed another body of mutineers. As brigadier-general, on September 14 he led the first column of attack at the siege of Delhi, and after the troops had forced their way into the city he still exposed himself in the most fearless manner, and fell, shot through the body. He died on 23d September 1857. Over the whole of India it was felt that, to use Lord Canning's expression, 'a tower of strength' had fallen.

See Kaye's *Lives of Indian Officers* (1867; new ed. 1889); the *Lives of Lord Lawrence* (q.v.); and L. J. Trotter's *Life of John Nicholson* (1897; new ed. 1905).

Nicholson, WILLIAM, artist and engraver, born in 1872 at Newark-on-Trent. After studying in Paris he collaborated with his brother-in-law James Pryde, and under the name of 'Beggartstaff Brothers' they produced many striking poster designs. In 1898 he published *Alphabet*, an *Almanac of Twelve Sports* (with Rudyard Kipling), and *London Types*, illustrated with remarkable woodcuts, where he made use of large masses of sombre shades relieved with splashes of bright colour. As a painter of still life he is notable, his picture 'Zinnias' being one of the greatest flower paintings of modern time. He is equally distinguished as a portrait painter, his paintings of W. E. Henley, Sir W. C. Packenham, and Miss Jekyll being good examples of his work. In the latter, indeed, he joins the realism of the 17th century Dutch painters to the decorative qualities of Japan.

Nicias, a famous Athenian statesman and general during the Peloponnesian war, was the son of Niceratus, a very wealthy citizen, who had acquired his fortune by working the silver-mines at Laurium. He belonged to the aristocratic party, and after the death of Pericles was the chief opponent of the demagogue Cleon, and later of Alcibiades. In 427 B.C. he captured the island of Minoa, next year he ravaged the island of Melos and the coasts of Locris, the next he compelled the Spartan force in Sphacteria to surrender, and defeated the Corinthians. In 424 he ravaged part of Laconia and captured the island of Cythera. After the death of Cleon he brought about a peace between the Spartans and Athenians, 421. Six years later the Athenians at the instigation of Alcibiades resolved on a great naval expedition against Sicily. Nicias was appointed one of the commanders, although he had strongly protested against the undertaking. In the autumn of 415 he laid siege to Syracuse, and was at first successful, but subsequently experienced a series of disasters; his fleet was destroyed, and his troops began a retreat towards the interior of Sicily. They were speedily forced to surrender, and Nicias was put to death in 414. See the *Histories of Greece*, Plutarch's *Life of Nicias*, and A. J. Church, *Nicias and the Sicilian Expedition* (1899).

Nickel (symbol, Ni; atomic weight, 58.7; atomic number, 28; specific gravity, 8.6-8.9), a white metal first isolated by Cronstedt in 1751. Nickel is similar to iron, chemically and physically, and shares with iron and cobalt the distinction of having magnetic properties. The arsenide of nickel being at first mistaken by the mediæval Saxon miners for a copper ore, they called it *Kupfer-nickel* (*Kupfer*, copper; *Nickel*, a refractory or stubborn individual), because it refused to yield copper—whence the origin of the name nickel. In a pure state the metal is malleable and ductile, and possesses a high tensile strength. The tensile

strength of annealed nickel seldom falls below 30 tons per square inch, while that of the cold-rolled metal may reach 45 tons. It can be pressed, spun, cast, forged, welded, and rolled upon other metals. Nickel has many uses in the arts and in industry. Its immunity from attack by most acids and alkalis, and its non-tarnishing quality, make it suitable for culinary vessels, receptacles for storing food, large boiling-pans, laboratory crucibles and dishes, &c. The high melting-point of the metal (1452° C., or 2645° F.), combined with its reasonable price, makes it serviceable for the electrodes of sparking-plugs, and for ionic or wireless valves.

The alloys of nickel are numerous and valuable. The best known is 'nickel silver,' or 'German silver'; it contains copper, zinc, and nickel, the percentage of the latter metal ranging from 5 to 35; it is used for electro-plated goods, railway carriage and cabin fittings, and for making wire of high electrical resistance. The nickel-iron alloy occurs in nature in most meteorites, and Faraday and Stoddart produced it artificially in 1820. Nickel-steel is enormously used. The addition of small proportions of nickel increases the tensile strength of a steel by about 4500 lb. per square inch for each 1 per cent. of nickel. Nickel-steels containing from 3 to 5 per cent. nickel are used in bridge-construction, and in the automobile and aeroplane industries. A steel containing 25 per cent. nickel is almost non-magnetic; it is employed on ships in the neighbourhood of magnetic instruments, and in the manufacture of electrical alternators. 'Invar' is a steel with 36 per cent. nickel; its coefficient of expansion is negligible, a property which makes it valuable for surveyor's tapes, clocks, and scientific apparatus. If the percentage of nickel be increased to 46 we get 'platinite,' whose coefficient of expansion is the same as that of glass. Platinite is employed for leading-in wires passing through the glass of electric-light bulbs, &c.

Where toughness and high tensile strength are necessary, steels having 4 or 5 per cent. nickel and small proportions of manganese and chromium are much favoured; they are adopted for crank-shafts, engine parts, gear-wheels, cams, couplings, &c., in general engineering, and especially in motor-car and aeroplane construction. Nickel-chromium steel is also largely used for armour-plate. Non-rusting and acid-resisting steels also contain nickel and chromium, though the latter metal is, in these cases, in higher proportion.

Nickel and nickel-copper alloy are used by most countries for coinage purposes. Spanish coins introduced after the Great War are of an alloy of nickel, aluminium, and copper. 'Cupro-nickel' (20 Ni, 80 Cu) is a white, ductile, and malleable alloy, used, *inter alia*, for bullet-envelopes. 'Monel metal' (70 Ni, 30 Cu) has high tensile strength, is very resistant to corrosion, and is extensively used for woven-wire gauzes, tubes, &c. Nickel-plating is an important industry, with very wide applications; essentially it consists in depositing a layer of nickel electrolytically on some other metal; the electrolyte is usually a solution of nickel-sulphate or nickel-ammonium sulphate, to which other salts (sodium and ammonium chlorides, boric acid, &c.) are added. New uses for nickel and its multitudinous alloys are found every year.

By far the most important source of nickel is the nickeliferous pyrrhotine (magnetic sulphide of iron) of Sudbury, Ontario; these deposits, of which about thirty are known in an area of 36 miles by 16 miles, yield over 3 million pounds' worth of the metal per annum. The ore is smelted locally, and the resulting matte is treated for the metal in Canada, the United States, and Britain. Monel metal is produced from Sudbury ore. The Sudbury nickeliferous masses are large and of irregular shape,

occurring at or near the margin of a big intrusion of norite (a variety of diorite); associated with them are numerous other intrusives—e.g. granite, quartz-norite, and basic dykes. Second in importance stand the New Caledonian deposits of garnierite (green and brown hydrated nickel-magnesium silicate). Discovered by Garnier in 1865, the New Caledonian deposits ranked for nearly forty years as the world's principal source of nickel, until they were outclassed entirely by those of Canada. The garnierite lies in pockets and patches in serpentine. The average yield of the ore is about 7 per cent. nickel. Nickel is also produced from the arsenical silver-cobalt ores of the Cobalt district, Ontario. Nickel and cobalt are nearly always found together. Of potential significance are the sulphide ores of the Insizwa region, Griqualand East, South Africa; here, as at Sudbury, the nickel occurs with iron and copper sulphides, closely connected with masses of norite and other intrusives. Nickel ore is found in Scandinavia, particularly in Evje, Høle and Torvestad, Norway. The Norwegian and Sudbury deposits are similar, but the former are the lower in grade, the ore containing about 2 per cent. of nickel.

Other nickel minerals are: *Nicolite* or *kupfernickel*, NiAs, found in Norway, Canada, Germany, United States, &c.—until about 1875 the chief source of the metal; *millerite*, NiS; *pentlandite* (Fe Ni)S; *chloanthite*, NiAs₂; *rammelsbergite*, NiAs₂; *breithauptite*, NiSb; *annabergite*, Ni₃As₂O₅·8H₂O. A considerable amount of natural nickel-chromium steel is made in America by the direct smelting of ore from Mayari, Cuba, the pig-iron produced containing from 1 to 1·5 per cent. nickel and 2·5 to 3 per cent. chromium.

The metallurgical treatment of Sudbury ore is as follows: The ore is crushed, and obvious waste removed by hand-picking; it is then reduced by means of blast or reverberatory furnaces to a low-grade matte assaying 15 to 25 per cent. nickel plus copper. The third stage is the conversion of the low-grade into a high-grade matte in Bessemer converters. In the latter operation air is blown through the molten mass; most of the sulphur is expelled as sulphur dioxide, and nearly all the iron is changed to oxide and enters the slag. The resulting Bessemer matte contains about 80 per cent. of nickel plus copper; it is cast into 'bricks,' and is sold to the refiners. There are four refining processes in use—namely, the Mond process worked near Swansea, the Orford process of Canada and the States, the French and Belgian processes adopted for New Caledonian ore, and the electrolytic process.

The Mond process was discovered in 1889. It depends on the fact that nickel, unlike other metals, easily unites with carbon monoxide to form a volatile carbonyl with the formula Ni(CO)₄. The finely-crushed matte is first calcined to expel sulphur; it is then treated with hot, dilute sulphuric acid, which carries off the bulk of the copper in solution as sulphate. The insoluble portion, consisting principally of nickel oxide, is passed through tall iron vessels, where it is brought into intimate contact with water-gas containing 55 per cent. hydrogen at a temperature of 350° C. Here the nickel is reduced to the metallic state. In the next stage the impure metal is treated in 'volatilisers' with carbon monoxide; the carbonyl is formed, and passes forward with the excess of carbon monoxide. Dust is filtered out, and the gas enters an apparatus filled with nickel pellets of various sizes kept in slow movement and at a temperature sufficient to decompose the carbonyl, again liberating carbon monoxide, which returns to the volatilisers. The pure nickel is deposited

as a skin on the pellets, which thus grow in size until they are large enough to be removed for sale. In the Orford process the Bessemer matte is fused with sodium sulphide, which combines with the copper and iron sulphides but not with nickel sulphide; the latter accordingly settles to the bottom of the molten mass, and is removed, ground, and roasted with common salt. During the last operation any residual copper is converted into soluble sulphate and chloride, the nickel remaining as insoluble oxide. The product is leached with water, and the copper thus dissolved away. The nickel oxide is then reduced to the metal in reverberatory furnaces.

Owing to the absence of copper, the treatment of New Caledonian matte is simpler. It is crushed and roasted until almost free of sulphur. The product (nickel oxide) is mixed with a little binding material and shaped into cubes or rondelles; these are dried and reduced with charcoal at 1200° C. or 1300° C. for twenty-four to forty-eight hours, thus yielding the metal.

When electrolytic refining is used, the matte is smelted with reducing agents to give an impure copper-nickel alloy, which is cast into plates. These serve as anodes in large cells, having iron cathodes and an electrolyte of nickel sulphate. The nickel passes across to the cathode, and forms a plate on each side of it. Precautions are taken to prevent copper also being deposited. When the nickel plates are thick enough, the cathodes are removed, washed, and the nickel stripped off.

Nickel forms two insoluble oxides, i.e. the *monoxide*, NiO, and *sesquioxide*, Ni₂O₃. The soluble sulphate, NiSO₄·7H₂O, is the most important of nickel salts. The soluble chloride, NiCl₂, and the insoluble oxalate and carbonate are also well known. The majority of nickel salts are green in colour. The soluble ones have a sweetish, astringent, metallic taste, and act as emetics.

Nicker (O.E. *nicor*, pl. *niceras*, in *Beowulf*), a malignant kind of water-sprite in Teutonic mythology. He often presents himself on the shore in the shape of a horse, and has thus close affinities with the Scottish *kelpie*; while indeed the Old Norse *níkr* (Old High Ger. *nichus*) is thought by some to mean the hippopotamus only. In our own demonology we find both a male *nix* and a female *nicie*. The modern Dutch *nikker* is merely an ordinary evil spirit or devil, recalling our own familiar *Old Nick*.

Nicobar Islands, a group of islands in the Indian Ocean, forming with the Andamans, to the south of which group they lie, an extension of the great island chain of which Java and Sumatra are the principal links. Nineteen in number, of which twelve are inhabited, they consist of two divisions—the northern, low and planted with coconut trees, and the southern, mountainous (2000 feet) and covered with timber. The temperature seldom moves outside the limits 80°–85° F. Excluding the Shom Pen (estimated at 375), a tribe of obscure origin, typically Malay in appearance, inhabiting the interior of Great Nicobar, the Nicobarese form one race of uniform Mongolian origin, but divided by physical characters, language, and customs into groups, each inhabiting a separate island or group of islands. There is a strong Malay element in the languages of the Nicobarese and in the physical appearance of the inhabitants of the southern islands. They collect and export trepang and edible birds'-nests. The archipelago was occupied by Denmark from 1756 to 1848. In 1869, with the consent of the Danish government, it was annexed by Britain, to stop local piracy. From 1869 to 1888 there was a branch of the Port Blair penal settlement at Nankauri on the island Kamorta. The

islands are administered from Port Blair in the Andaman Islands. Pop. (1921) 9017 (Nicobarese 8248; Shom Pen estimated at 375); of these 6352 were on Car Nicobar, the most northerly island (49 sq. m.).

Nicodé, JEAN LOUIS, Prussian pianist, conductor, and composer, born in 1853 at Jerczig, near Posen. Educated at first by his father and Hartkäss, he studied music afterwards at Berlin under Kullak, Wüerst, and Kiel. He taught music in Berlin, then toured with Mme. Artôt in Galicia, was for a time a professor at Dresden Conservatory, and in 1885-88 conducted the Philharmonic concerts. From 1896 he was director of the Dresden Neustadt Chorgesangverein. He retired to Langebrück near Dresden in 1900, and died there 5th October 1919. A conductor of insight and a pianist of considerable art, Nicodé enjoyed wide popularity. Of his numerous compositions may be cited *Marie Stuart* (1881), *Die Jagd nach dem Glück* (1882), *Das Meer* (1888), *Gloria* (1904), all symphonic poems of high rank. See Th. Schäfer, *J. L. Nicodé* (1917).

Nicodemus, GOSPEL OF. See APOCRYPHA.

Nicolai, CHRISTOPH FRIEDRICH, bookseller and publisher at Berlin, was born 18th March 1733, and early distinguished himself by a series of critical letters (1756), in which he exposed the errors of both Gottsched and Bodmer, then carrying on a controversy which was agitating the literary world of Germany. With Moses Mendelssohn he edited the *Bibliothek der schönen Wissenschaften* (1757-58), and contributed with Lessing to *Briefe die neueste deutsche Literatur betreffend* (1759-65). By this he was led to conceive the plan of the *Allgemeine deutsche Bibliothek* (106 vols. 1765-92), a periodical which he edited for many years, and which contributed to the progress of literature and improvement of taste in Germany, but drew ridicule from the inability of its editor to appreciate the new spirit that was stirring in Herder, Goethe, Schiller, Kant, and others, with all of whom he was at feud. He wrote topographical works, satires, anecdotes of Frederick the Great, and an autobiography, in which he describes strange apparitions or obvious hallucinations by which he was visited. He died 8th January 1811.

Nicolai, OTTO (1810-49), musical composer, born at Königsberg, in early life had a sore struggle with poverty and difficulties. He studied in Berlin and in Rome, and in 1847 became Kapellmeister at Berlin. His best-known work is the opera *The Merry Wives of Windsor* (1848).

Nicolaus of Cusa. See CUSA.

Nicolaitans, an immoral sect mentioned in Rev. ii. 6, 15, and sometimes, but apparently on very feeble grounds, connected with Nicolas the proselyte of Antioch, mentioned in Acts, vi. 5. Indeed the name seems rather to be symbolic than historical, the Greek *Nikolaos* being an equivalent to the Hebrew *Balaam*. In this sense the passage in the Apocalypse harmonises closely with what is said of the followers of Balaam in Jude and 2 Peter, and Rev. ii. 15 need not be taken as referring to a different class from verse 14. Their error was a licentiousness which they brought into the Christian church from the heathen world, and the subtler wickedness of defending this as supported by a doctrine and a prophetic illumination (2 Pet. ii. 1). There is no satisfactory evidence of the existence of such a sect after the time of John; still Irenæus mentions the Nicolaitans as a sect of Gnostics of the Ophite class, and in this he is followed by Hippolytus.

Nicolas, ST, the patron saint of Russia, whose life is wrapped in an obscurity that is but little lightened by fable. He was bishop of Myra in

Lycia, and according to Metaphrastes was imprisoned under Diocletian and released under Constantine. The statement that he was present at the Council of Nice is in the highest degree improbable. His supposed relics were conveyed from the East to Bari, in the kingdom of Naples, on 9th May 1087; and it is a curious fact that in the Russian Church the anniversary of this translation is still observed as a festival. In Catholic countries St Nicolas is especially the patron of the young, and particularly of scholars. In England his feast was celebrated in ancient times with great solemnity in the public schools, Eton, Sarum Cathedral, and elsewhere; and still in Germany on the vigil of his feast, which is held on the 6th December, a person in the appearance and costume of a bishop assembles the children of a family or of a school, and distributes among them, to the good children, gilt nuts, sweetmeats, and other little presents, as the reward of good conduct; to the naughty ones, the redoubtable punishment of the 'Klaubauf.' *Santa Claus* is an American corruption of the name Sante Klaas (for Sint Nicolas); the old Dutch settlers of New York kept a San Claus holiday. St Nicolas was patron of merchants, sailors, and travellers; and as he was prayed to for protection against robbers, these came, oddly enough, to be called 'Clerks of St Nicolas.' See Littlewood's *Story of Santa Claus* (1912).

Nicolas, SIR NICHOLAS HARRIS, antiquary, was born 10th March 1799, of a Cornish family of Breton origin. He entered the navy, and had reached the rank of lieutenant by 1815, but at the close of the war left the service to study law, and was called to the bar at the Inner Temple in 1825. He devoted himself chiefly to genealogical and historical studies, and his great work, the *History of the Orders of Knighthood of the British Empire* (4 vols. 1841-42), remains a solid monument of learning. Harris was made K.H. in 1831, and K.C.M.G. in 1840, and died at Cape Curé, near Boulogne, August 3, 1848. He devoted the energies of his later years to works on the naval history of England: *Dispatches and Letters of Admiral Lord Viscount Nelson* (7 vols. 1844-46), and the unfinished *History of the British Navy* (2 vols. 1847), as well as the papers of Sir Hudson Lowe. Harris wrote biographical notices of many of the poets in Pickering's Aldine edition, as well as many useful historical handbooks, as a *Synopsis of the Peerage of England* (1825), *Testamenta Vetusta* (1826), the *Chronology of History* (1835). Other works are *Proceedings and Ordinances of the Privy Council of England* (7 vols. 1833-37); a *Life of William Davison*, Queen Elizabeth's secretary and scapegoat in the execution of Mary, and an ancestor of his wife's (1823); *Memoirs of Ritson* (1833); and a host of books and papers—and all of value—on heraldic, genealogical, antiquarian, and historical questions. A list of these is given in the *Gentleman's Magazine* for October 1848.

Nicolaus de Lyra. See LYRA.

Nicole, PIERRE (1625-95), one of the most distinguished of the Port Royalists (see PORT ROYAL, JANSEN), friend of Arnauld and Pascal.

Nicoll, ROBERT (1814-37), minor poet, born at Little Tullybeltane, in Perthshire, published *Songs and Lyrics* in 1835. In 1836 he became editor of the radical *Leeds Times*, but worked too zealously for his health, and died of consumption.

See the Life by Mrs Johnstone, prefixed to the 1842 and other editions of the poems, including the centenary edition (1914); and the somewhat uncritical life, by P. R. Drummond (published posthumously, 1884).

Nicomedia, the capital of ancient Bithynia, situated at the north-eastern angle of an inlet of the Propontis, was built in 264 B.C. by Nicomedes I.

It soon became one of the most magnificent and flourishing cities in the world, and some of the later Roman emperors, such as Diocletian and Constantine the Great, selected it for their temporary residence. It suffered greatly from earthquakes. Hannibal committed suicide in a castle close by, and Constantine died near the city, which was the birthplace of the historian Arrian. The small town of Ismid now occupies its site. See BITHYNIA for Nicomedes.

Nicopolis, a town of Bulgaria, with 8000 inhabitants, is on the Danube, 56 miles W. of Rustchuk. The Berlin Congress of 1878 provided for the demolition of the fortifications. Here the Hungarians were defeated by the Sultan Bajazet in 1396; and the place has been more than once taken by the Russians (1810, 1827, 1877).

Nicosia, (1) called also LEVKOSIA, the capital of Cyprus, situated near the middle of the northern half of the island, is surrounded with old Venetian walls, and is the residence of the British High Commissioner, and the see of a Greek archbishop. There are numerous mosques and churches, and some manufactures of silk, leather, and cotton. Pop. 18,000.—(2) A city of Sicily, 40 miles NW. of Catania. Pop. 15,000.

Nicot, JEAN, born at Nîmes in 1530, died at Paris in 1600, French ambassador at Lisbon, introduced into France the tobacco-plant, which was called after him *Nicotiana* (see TOBACCO). He also compiled one of the first French dictionaries, *Trésor de la Langue Française* (1606).

Nicotine, $C_{10}H_{14}N_2$, is a volatile liquid alkaloid, and constitutes the active principle of the tobacco-plant, in all parts of which it occurs in combination with malic and citric acids. It is likewise contained in minute amount in the smoke of the burning leaves. When pure and freshly prepared it is a colourless, intensely poisonous liquid, which evolves a very irritating odour of tobacco, but on exposure to the air it rapidly oxidises and becomes brown in colour. It is moderately soluble in water, and dissolves readily in alcohol and ether. The quantity of nicotine in tobacco varies from 2 to 8 per cent.; the coarser kinds contain the larger quantity, while the best Havana cigars seldom have more than 2 per cent., and often less. Locally, nicotine is very irritating. Taken internally, it is one of the most powerful poisons known; $\frac{1}{16}$ grain taken by the mouth has caused in man distinct symptoms of poisoning, there being first seen a short stage of excitement, followed by headache, vertigo, great weakness, and general depression. Larger doses ($\frac{1}{8}$ grain) cause in addition trembling, vomiting, collapse, and great depression of the heart and respiration. A single drop is sufficient to kill a rabbit or cat in a few minutes.

Nitheroy, a town of Brazil, capital of the state of Rio de Janeiro, on the east side of the entrance to the bay, and 5 miles E. of the city of Rio de Janeiro. It has beautiful suburbs. Pop. 86,000.

Nititating Membrane. See BIRD, EYE.

Nidderdale, the valley of the river Nidd, which rises at the foot of Wharfedale, in Yorkshire, flows south-east and east, and joins the Ouse a few miles above York. The upper portion of the stream flows through picturesque scenery, and past Ramsgill, the birthplace of Eugene Aram.

Niebelungen. See NIBELUNGEN.

Niebuhr, BARTHOLOMÆUS GEORG, one of the most distinguished of modern historians, was born 27th August 1776, at Copenhagen, the son of the famous traveller, Karsten Niebuhr. From his infancy he showed unusual promise, and he was carefully educated under his father's eye. After

his studies at Kiel he became private secretary to Count Schimmelmann in Copenhagen, and devoted himself to the study of the natural sciences at London and Edinburgh (1798-99). In 1800 he married and entered the Danish state-service, and held various appointments, which he resigned in 1806 to enter the Prussian civil service on the invitation of Stein. During the next three years, the darkest in the history of Prussia, Niebuhr was actively employed in public business and in various secret financial missions. But his scholar's temperament was but ill adapted for political intrigue, and the opening of the university of Berlin in 1810 proved a new era in his life. He gave (1810-12) a course of lectures on Roman history which, by making known the results of the new and critical theory that he had applied to the elucidation of obscure historical evidence, established his position as one of the most original and philosophical of modern historians. His appointment, in 1816, to the post of Prussian ambassador at the papal court, where he remained till 1823, gave him an opportunity of testing on the spot the accuracy of his conjectures in regard to many questions of local and social bearing. On his return from Rome Niebuhr took up his residence at Bonn, where his admirable lectures gave a powerful impetus to classical and archaeological learning. He was thus employed when the revolution of 1830 led to mental depression and bodily prostration, which ended in his death, 2d January 1831.

Of his *Römische Geschichte* (vols. i. and ii. 1811-12; 2d ed. 1827-28; vol. iii., coming down to end of first Punic war, edited from his papers by Classen, 1832) the first two volumes were translated by Julius Hare and Connop Thirlwall, and the third by Dr W. Smith and Dr L. Schmitz; other works translated by Schmitz into English are *Lectures on the Hist. of Rome, to Fall of Western Empire* (2d ed. 3 vols. 1850), *Lectures on Ancient Hist.* (3 vols. 1852), and *Lectures on Ancient Ethnography and Geog.* (2 vols. 1853). Other works are *Griech. Heroengeschichte* (1842), written for his son Marcus; *Kleine historische und philologische Schriften* (2 vols. 1828-43); besides numerous other essays on philological, historical, and archaeological questions. Niebuhr co-operated with Bekker and others in re-editing *Scriptores Historie Byzantine*; he also discovered hitherto unprinted fragments of classical authors, as of Cicero's *Orations* and portions of Gaius; published the *Inscriptiones Nubienses* (Rome, 1821); and was a constant contributor to the literary journals of Germany. See Madame Hensler's *Lebensnachrichten* (1838; Eng. trans. by Miss Winkworth, 3 vols. 1852), and the studies by Classen (1876) and Eysenhardt (1886).

Niebuhr, KARSTEN, a distinguished geographer and traveller, was born in 1733, in the Hanoverian territory of Hadeln. He spent several years as a day-labourer; but having acquired a small property, he studied at Göttingen, entered the Danish service, and in 1761 joined an expedition to explore portions of Arabia, Persia, Asiatic Turkey, and India. On his return to Denmark in 1767 he published the results of his mission, *Beschreibung von Arabien* (Copenhagen, 1772), and *Reisebeschreibung* (3 vols. 1774-98). He also edited and published at his own cost the natural history notes of his deceased friend and fellow-traveller, P. Forskål, *Descriptiones Animalium* (1775) and *Flora Ægyptiaco-Arabica* (1776). He accepted in 1778 a civil post at Meldorf, in the Ditmarsh district of Holstein, then Danish. He died 26th April 1815. See his son's *Leben Niebuhrs* (1817).

Niederwald, the western termination of the Taunus range, that abuts upon the Rhine over against Bingen. On a commanding site near its summit was erected, on 28th September 1883, the national (German) memorial commemorative of the successful war of 1870-71. An extensive pedestal, ornamented with allegorical figures, is

surmounted by a bronze figure of Germania, 34½ feet in height. The whole was designed by Schilling, a Dresden sculptor. Below are the villages of Rüdesheim and Assmannshausen, both noted for wine.

Niel, ADOLPHE, French marshal, was born at Muret (Upper Garonne) on 4th October 1802, and entered the army as an engineer officer; he took part in the storming of Constantine in Algeria (1836), the siege of Rome (1849), the bombardment of Bomarsund in Finland (1854), the fall of Sebastopol (1856), and in the battles of Magenta and Solferino (1859). His share in these battles won him the marshal's baton. He was made minister of war in 1867, and was busily employed reorganising the French army when he died, 14th August 1869. It is from him that the favourite Marshal Niel (yellow) rose derives its name.

Niello-work (Ital. *niello*, from Low Lat. *niellum*, 'black enamel'), a method of ornamenting silver or gold plates by engraving the surface, and filling up the lines with a black composition to give clearness and effect to the incised design. The plates so ornamented were principally employed in the making of church-plate reliquaries, and for costly personal ornament. Traces of the art are found in ancient Roman work, and it was much practised under the Byzantine empire from the 16th century onwards. The Italian goldsmiths attained remarkable skill in niello-work; and the most eminent and famous of these was the Florentine Maso or Tommaso Finiguerra, whose work, in addition to its artistic excellence, derives peculiar interest from the fact that he, being the first to take paper proofs from his engraved work, directly led the way to the production of line-engravings. The name *niello* is given not only to the engraved and niellated metal-work, but also to the paper proofs taken from them; and as these were only casually taken they are very rare, and bring great prices, as much as 300 guineas having been paid for a single small proof. Niello-work is still practised by goldsmiths, especially in Russia, the silver niellated boxes made in that country being popularly known as 'platina boxes.' See ENGRAVING.

Niemen, or MEMEL, a river of Poland, Lithuania, and East Prussia, rises a few miles south of Minsk, and its two branches reach the Kurisches Haff each by four mouths. See TILSIT.

Niepce, JOSEPH NICÉPHORE (1765-1833), was born at Chalon-sur-Saône, served in the army in Italy, and in 1795 became administrator of the district of Nice. Returning to Chalon in 1801, he made those experiments with sunlight pictures which made Photography (q.v.) possible.—His nephew, CLAUDE MARIE FRANÇOIS NIEPCE DE ST VICTOR (1805-70), also a soldier, wrote a *Traité Pratique* (1856) on photography, and *Recherches Photographiques* (1855).

Nierstein, a Hessian village on the Rhine, 10 miles SSE. of Mainz, famous for its wine.

Nietzsche, FRIEDRICH, the most brilliant writer in point of style that Germany has recently produced, attracted wide-spread attention in the closing years of the 19th century by his uncompromising attack on accepted standards in ethics, religion, and social theory. Born at Röcken, in Saxony, on the 15th October 1844, the son of the village pastor, Nietzsche was educated at the old grammar-school of Schulpforta and at the universities of Bonn and Leipzig. He showed such distinction in classical scholarship that in 1869, before he had formally completed his degree, he was appointed Professor of Classical Philology in the university of Basel, a post which he continued to hold for ten years, till ill-health compelled him to resign it. During his student years at Leipzig he had become an en-

thusiastic disciple of Schopenhauer, whose doctrine of renunciation and whose theory of art as the realm of consolation alike appealed to his nature. He had also made the personal acquaintance of Wagner, of whose music he was an ardent admirer. These were the influences which moulded Nietzsche's thought in its earliest phase. From Basel he was a frequent visitor at Wagner's villa on Lake Lucerne, and to Wagner he dedicated his first book, published in 1871. *The Birth of Tragedy from the Spirit of Music, or Hellenism and Pessimism*, points, indeed, with no uncertain finger to Wagnerian opera as the true successor of the tragic drama of the Greeks. Although an exceptionally brilliant handling of the much-discussed question of the origin of Greek tragedy, the work was coldly received in philological circles, and Nietzsche first attracted more general attention by the four essays, published between 1873 and 1876, under the general title of *Unseasonable Reflections* (*Unzeitgemässe Betrachtungen*). Two of the essays express the author's obligations to Schopenhauer and Wagner; another on Strauss's *Old Faith and the New* is a deliberately planned attack upon an established reputation, in which Nietzsche pours contempt upon the German culture of the day. In the excellent essay on *The Advantage and Disadvantage of History for Life* he gives clear expression to the aristocratic ideal so prominent in his later writings—the view that the significance of history is to be found not in the movements of the masses ('copies on bad paper and from worn-out types,' as he calls them) but in great and heroic individualities. After 1876 a harsh and discordant note comes into Nietzsche's writings. The years between 1876 and 1882 were a period of mental crisis and transition; he described them afterwards as a time of mental sickness and lonely quest. In revulsion from the romantic pessimistic idealism which had hitherto been his inspiration, he flung himself into the analysis and history of the moral sentiments. His next book, *Human, All-too Human* (*Menschliches, allzu Menschliches*), dedicated to the memory of Voltaire, is written in a spirit of cynical naturalism which rejoices in dragging to light the animal impulses and undisguised selfishness to which it would reduce all human conduct. In this work Nietzsche adopted for the first time the literary form of the aphorism, which he used with remarkable success in most of his subsequent writings. Two further volumes, *Dawn* (*Morgenröthe*), 1881, and *The Joyful Science* (*Die Fröhliche Wissenschaft*), 1882, are written in the main from the same point of view, although, as the titles indicate, there is perceptible a gradual growth of new ideas, and in *The Joyful Science* (which Nietzsche described as celebrating his recovery from sickness) we have already a forecast of his final positions. The three books mentioned are frequently described as representing Nietzsche's second, or positivistic, period as distinguished from his earlier Schopenhauerianism and his later Zarathustrianism. The allegorical rhapsody or prose-poem, *Thus Spake Zarathustra*, which is probably the most characteristic product of his genius, appeared in parts between 1883 and 1885. A slender thread of narrative introduces a series of rhythmic chants in which Zarathustra, in the style of an Eastern prophet, develops the idea of the *Uebermensch*, or Superman, who is to revolutionise our accepted morality and religion, and realise in his own person the will for mastery and the cult of personal distinction which Nietzsche preaches as the foundation of all noble virtues. The literary beauty and power of many passages of the book and the elevation of the whole are acknowledged even by those who dissent most strongly from its teaching. Nietzsche's remaining works expound and apply these ideas in a series of brilliant aphorisms and

epigrams. *Beyond Good and Evil*, published in 1886, continues his attack upon existing moral values or standards, and formulates the distinction between two systems of morality—the morality of the masters, and the morality of the slaves. *The Genealogy of Morality* (1887) is an attempt to substantiate this distinction by reference to etymology and history. In 1888 he published *The Case against Wagner*, a strange outburst against the friend and master of former years; and in 1889 appeared *The Twilight of the Idols*, the last of his works given to the world by himself. His health, originally undermined by dysentery contracted in the Franco-German war of 1870, had led to the resignation of his Basel professorship, and from 1880 onwards he had lived at various health-resorts in Italy and the Engadine. Suffering from insomnia and constantly recurring attacks of migraine, he had contracted the habit of dosing himself with powerful drugs, which in the end but aggravated the mischief, and early in 1889 his long nervous derangement culminated in hopeless insanity. For eleven years he was lovingly tended, first by his mother and then by his sister, Frau Foerster-Nietzsche, who has written his Life. He died at Weimar on the 25th of August 1900. His latest works are disfigured by their colossal egotism, amounting to megalomania, and by the hysterical violence of their attack upon Christianity.

Though Nietzsche is fond of the title 'immoralist,' and describes his position as 'beyond good and evil,' his real meaning is better expressed in another of his phrases as 'the transvaluation of all values'—the reversal of all accepted ideals. Zarathustra breaks the old tables of the law, but in the same breath the work of the creative thinker is proclaimed to be the writing of new values, on new tables. Slave-morality, the morality of the herd, has in fact to be exchanged for master-morality, for the aristocratic or 'noble' virtues. Humility, compassion, self-sacrifice, as inculcated by Christianity, are the virtues of the poor, the oppressed, and the suffering, and the pursuit of happiness is the ignoble ideal of the common herd of mankind. But the 'free man is a warrior,' and the virtues of a ruling class are courage, self-reliance, the cult of distinction, a proud consciousness of their own superiority, and a lofty acceptance of the self-sacrifice of others. Nietzsche's later works are one long denunciation of the altruistic, humanitarian, and democratic ideals of modern civilisation, all of which he finds rooted in Christianity, the great 'revolt of the slaves in morality.' He summarises the whole process of European history during the last two thousand years as a conflict between Rome and Judæa; and in the Superman the heroic Roman type is to be revived. Nietzsche's thought was also profoundly influenced by biological conceptions. Interpreting the principle of natural selection on purely naturalistic lines, he condemned sympathy as thwarting the law of development. 'The weak and ill-constituted shall perish,' he says, 'first principle of our charity; and people shall help them to do so.' In the unbalanced writings which preceded his final collapse the violence of his polemic against a scale of values which is responsible, he holds, for the deterioration of the race, leads him to celebrate the beast of prey as the original type of 'noble' virtue, and he comes perilously near abandoning moral standards altogether. But this is a declension from the more strenuous ideal which Zarathustra preaches. Apart from the paradox and suggestion of his negative polemic there is a tonic value in Nietzsche's insistence on the heroic virtues, on the function of great personalities, and on distinction alike in character and in act. The nobler side of his teaching is also seen in his repudiation of the pessimism which is

often the result of a relaxation of moral fibre, in his glorification of life and energy, and the mood of resolution—enthusiasm mingled with defiance—with which he accepts the best and the worst that the universe has to offer. The doctrine of 'eternal recurrence,' which he borrowed from Heraclitus and the Stoics, becomes for him a symbol of this attitude of triumphant acceptance. On the other hand, his naturalistic gospel of the forceful Ego allies itself with the spirit of militarism and the worship of force, which constitutes a standing menace to the future of civilised humanity.

A complete English edition of Nietzsche's works has been published in eighteen volumes, edited by Dr Oscar Levy. Mügge's *Nietzsche, his Life and Works*, contains a very full bibliography of the already voluminous Nietzsche literature.

Nièvre, a central department of France, on the watershed between the Loire and the Seine. Area, 2632 sq. m.; pop. (1881) 347,576; (1921) 270,148. Mountains of the Morvan system, which forms the watershed between the Seine and Rhone, divide the department into two great declivities. There are plateaus more or less fertile, vine-clad hills, and valleys rich in pastures; but the principal wealth of the department consists in its forests and minerals—coal, iron, and gypsum. The Nièvre is an inconsiderable affluent of the Loire from the right. The three chief rivers are the Allier, Loire, and Yonne. The iron industry is important, and pottery and glass are made. The capital is Nevers.

Niflheim. See SCANDINAVIAN MYTHOLOGY.

Nigella, a genus of plants of the natural order Ranunculaceæ, having five coloured spreading sepals; five or ten small two-lipped petals, with tubular claw; the carpels more or less connected together, many-seeded; the leaves divided into threadlike segments, the flowers solitary at the top of the stem or branches. They are annuals, natives chiefly of the Mediterranean countries and warm temperate Asia. Some of them, occasionally seen in gardens in Britain, are vulgarly known as *Devil-in-a-mist*. The seeds are aromatic and somewhat peppery. Those of *N. sativa*, a species common in cornfields in the south of Europe, are supposed to be the Black Cummin of the ancients, and perhaps the Cummin of the Bible.

Niger, the name now generally applied to one of the most remarkable river-systems of West Equatorial Africa, first appears in Ptolemy as designating, it is believed, the modern Wadi Draa, and coupled with a river Gir, which may be identified with the modern O-Guir, flowing southward from the Atlas towards the oases of Tuat. The word not improbably contains the root *gir*, *gar*, or *jur*, not infrequent in the river-names of northern Africa. Mixed up as it was from time to time with the problem of the Nile, the problem of the Niger remained almost till the 19th century one of the most perplexed and bemuddled in the whole range of geography. Though the Portuguese had ascended the river from the sea in the 16th century, the most contradictory opinions were held as to its character and relations down to the later part of the 18th century; it was an affluent of the Nile; an affluent of the Congo; an independent river terminating in an inland basin; and so on. It was still left to Mungo Park and other workers in the service of the African Association to lay the basis of our present knowledge of the system. Lander (1830) proved that it enters the sea through the great delta of which the Nun is the principal mouth. Other explorers were Clapperton, Barth, Houst, and Lenfant.

The Niger proper (Joliba or Dhiuliba, Isa, Kworra or Quorra, &c.) has a total length of 2600 miles, and the area of the entire basin (including that

of the Benué) is estimated at 1,023,280 sq. m. The head-waters are situated in French Guinea, and are contiguous to those of the Senegal. The Tembi (first explored by Zweifel and Moustier in 1879), rising at a height of about 2800 feet above the sea in the Loma Mountains in 9° 5' N. lat. and 10° 47' W. long., is now accepted as the conventional 'source.' This and its sister streams, though draining a comparatively limited area, soon gather into a good navigable river, which holds a north-easterly course to its most northerly point near Timbuktu, first visited by Laing in 1826. About 300 miles above this famous city it is joined by an important right-hand tributary, the Bani or Mayel-Balevel, and develops a tendency to split up into numerous and widely diverging channels, with cross-creeks, back-waters, and swamps. Beyond Timbuktu a more easterly direction is maintained for 200 miles, and then with its now united forces the Niger turns south-east to cut its way through a rocky tract of country, and to pass in succession Gao (Gogo) on the southern skirt of the Sahara; Say, the southern point of Barth's exploration; Gompá, the northern limit of Flegel and Thomson; Bussa, where Park came to his untimely end; and Rabba, one of the largest cities on its course. During this long journey from Timbuktu (1130 miles) a chief characteristic of the Niger has been the insignificance of its tributary streams; but at last, in 7° 50' N. lat., 6° 45' E. long., it meets in the Benué, or Mother of Waters, a rival both in volume and in beauty.

Nigeria, a British protectorate in West Equatorial Africa, constituted 1st January 1900, includes all the territories occupied till that date by the Royal Niger Company, and the Niger Coast Protectorate. Lagos was added in 1906. It lies between Cameroon and Dahomey. Its southern boundary is the Gulf of Guinea. Crossing the Niger near Ilo, the boundary runs northward to about 14° N., whence its course is mainly eastward to Lake Tsad. It includes the whole of the lower basin of the Niger, and nearly the whole of its great tributary, the Benué. Its area is about 335,700 square miles, and the population is 18 millions. The Niger Coast Protectorate (known till 1893 as the Oil Rivers Protectorate), formed in 1844, extended from Lagos to the Rio del Rey River, including the so-called Oil Rivers, the whole Benin region (in 1897), and the Niger delta, except the portion between the Forcados and Brass rivers, and was administered under the Colonial Office by a commissioner and consul-general. The Niger territories were first occupied by the British United African Company in 1879, which by treaties with many native states and tribes finally acquired rights over the whole region now called Nigeria except the Niger Protectorate (about one-tenth). The territory of the company, which in 1886 obtained a charter as the Royal Niger Company, included the Fulah empire of Sokoto, the kingdom of Gando, the Borgu and Mossi countries, part of Adamawa, the western parts of Bornu, and other native states. In 1899 the government arranged to take over all the powers and rights of the company on 1st January 1900. Southern Nigeria, originally the Coast Protectorate and part of the Niger Protectorate, absorbed Lagos (q.v.) in 1906, and the whole was constituted the colony and protectorate of Southern Nigeria. In 1912 the colony and protectorate of Nigeria was reorganised under Sir F. Lugard as governor of the whole at Lagos, with lieutenant-governors for the Northern and the Southern Provinces. The Northern Provinces are fertile, with great agricultural resources, and fairly healthy. Cotton, indigo, rubber, hides, ivory, and minerals (silver, tin, and lead) are the chief products. The Hausa race form a large proportion of

the population, and are civilised and industrious. The chief towns are Kano (with railway to Lagos), Yola (capital of Adamawa), Wurno (capital of Sokoto), Gando, Bida, Ilorin, Yakoba, Sokoto, and Zaria. In the Southern Provinces Asaba, Benin, and Idda are the chief inland towns; and on the coast, Lagos, Wari, Barutu, Akassa, Brass, New Calabar, Port Harcourt, Bonny, Opoba, and Old Calabar. The chief products are palm oil and kernels, cocoa, rubber, ivory, indigo, gums, coffee, and hides. Coal is mined in the Enugu district, which has a railway to Port Harcourt and to the Benué.

See J. Scott Keltie, *The Partition of Africa* (2d ed. 1895); Möckler Ferryman, *British Nigeria* (1902); C. H. Robinson, *Nigeria* (1900); Hazzledine, *The White Man in Nigeria* (1904); Lady Lugard, *A Tropical Dependency* (1905); Dennett, *Nigerian Studies* (1910); E. D. Morel, *Nigeria: its Peoples and its Problems* (1911); C. W. I. Orr, *The Making of Northern Nigeria* (1912); and works by Falconer and by Trehearne (1912).

Niger Seed, the seed of a compositous plant, *Gnuzotia abyssinica*, cultivated in India and East Africa. It yields a substitute for linseed oil.

Night. See DAY.

Night-hawk. See GOATSUCKER.

Night-heron (*Nycticorax*), one of the genera of Herodiones (see HERON), including nine species. One species, *N. griseus*, widely distributed over the whole of Africa and southern Asia, and a migrant to places near the Baltic, has now become an almost annual visitor to the British Islands in spring and autumn. *N. naevius* (*Nyctiardea gardeni*, Baird) is the common American night-heron.

Nightingale (*Daulias*) a genus of Passerine birds of the family Turdidae. The bill is straight, slender, not quite as long as the head; the wings do not much pass beyond the base of the tail; the first quill is very short, the third is the longest; the tail is slightly rounded; toes long, claws rather short. The Common Nightingale (*D. lusciniæ*) is well known as the finest of songsters. It is rather larger than the hedge-sparrow, with about the same proportionate length of wings and tail. It is of a rich russet-brown colour above, shading into reddish chestnut on the tail-coverts and tail; the lower part grayish white; bill, legs, and feet brown.

Common Nightingale
(*Daulias lusciniæ*).

The sexes are alike in plumage. It is a native of many parts of Europe and Asia, and of the north of Africa, extending as far as to Abyssinia, and to the Gold Coast in West Africa, and it is a bird of passage, extending its summer migrations on the continent of Europe as far north as the south of Sweden, though in Britain it has scarcely ever been seen farther north than Yorkshire. It is plentiful in some parts of the south and east of England, but is less common in the western counties, and does not visit Scotland, Ireland, or Wales, except Glamorganshire and

Beacon. It frequents thickets and hedges and damp meadows near streams. The market-gardens near London are among its favourite haunts. It feeds very much on worms, insects and their larvæ. It arrives in England about the middle of April, the males about ten days before the females. It is at this season, and before pairing has taken place, that bird-catchers generally procure nightingales for cage-birds, as they then become easily reconciled to confinement, whilst if taken after pairing they fret and pine till they die. If nightingales, however, are to be kept in confinement they ought to be taken from the nest when young and reared by hand. The nightingale makes its nest generally on the ground, but sometimes on a low fork of a bush. It is loosely constructed of dead leaves, rushes, and stalks of grass, with a lining of fibrous roots. The eggs are from four to six in number, of a uniform deep olive-brown. The song of the male ceases to be heard as soon as incubation is over. In captivity, however, it is often continued through a more considerable period. The male bird sings by day as well as by night, but at night its song is most noticeable and characteristic. The variety, loudness, and richness of its notes are equally extraordinary; and its long quivering strains are full of plaintiveness as well as of passionate ecstasy. The nightingale has been a favourite from most ancient times, and is often mentioned in the poetry of India and Persia, of Greece and Rome, as well as by Shakespeare and Herrick, Keats and Coleridge, and many others, who are often thinking rather of Philomela (q.v.) than of the bird. The loves of the Bulbul (q.v.) and the rose are a fanciful theme in which eastern poets delight. The nightingale, as a rule, is not a shy bird, for although it is but seldom seen it seems to prefer to live near the abode of man; nor is it quarrelsome with others of its own species except at pairing time. A closely allied species (*D. golzii*) is found from the Caucasus to Turkestan and Persia, and in north-eastern and central Europe the Northern Nightingale or 'Sprosser' (*D. philomela*) is found, quite a distinct species, of rather larger size, less russet in hue, and slightly spotted on the breast.

Nightingale, FLORENCE, the daughter of W. E. Nightingale of Embley Park, Hampshire, was born at Florence, 15th May 1820. Keenly interested in the alleviation of suffering, she visited civil and military hospitals all over Europe; and in 1849-51 went into training as a nurse with the Deaconesses at Kaiserswerth and the Sisters of St Vincent de Paul in Paris. When after the battle of the Alma in September 1854 the sick and wounded were dying in thousands in the overcrowded hospitals on the Bosphorus, she offered to go out and organise a nursing department at Scutari. Lord Herbert had already written requesting her to go; and on the 21st of October she departed with thirty-four nurses. She arrived in time to receive the wounded from Inkermann into wards already filled with 2300 patients, and soon had 10,000 sick men under her care. She saw in the bad sanitary arrangements of the hospitals the causes of their frightful mortality, and devotedly set herself to the removal of these. Her devotion to the sufferers can never be forgotten. In the spring of 1855, while in the Crimea organising the camp-hospitals, she was prostrated with fever, yet remained at Scutari till Turkey was evacuated by the British in July 1856. A fund of £50,000 was subscribed to enable her to form an institution for the training of nurses at St Thomas's and King's College Hospitals. She gave valuable help in the reform of army hospitals, and published important *Notes on Nursing* (1858), *Notes on Hospitals* (1859), *Notes on Lying-in Institutions* (1871), *Life or Death in India*, and (in

Fraser's Magazine, 1873) 'A Note of Interrogation' on religious beliefs; also, in 1890, the article on Hospitals in *Chambers's Encyclopædia*. She assisted in founding the Red Cross Society. Lord Stanmore's Life of Lord Herbert (1906) shed new light on her somewhat autocratic management of affairs in the Crimean time. She died 13th August 1910. See Life by Sir E. Cook (1913).

Night-jar. See GOATSUCKER.

Nightshade, the English name of certain plants of the natural order Solanaceæ (q.v.), possessing the narcotic properties frequently developed in that order. Among them are some species of *Solanum* (q.v.), particularly the Common Nightshade, or Black Nightshade (*S. nigrum*), an annual or biennial, with erect angular stem, ovate, sinuate-dentate leaves, drooping lateral umbels of white flowers, and globose black berries; a frequent weed in waste places in England and in most parts of the world. Few plants are more widely diffused. It is only slightly narcotic. The leaves in a fresh state are said to be injurious to animals which eat them, but seem to lose almost all narcotic property by boiling, and are used as spinach, particularly in warm climates. The berries, although generally dreaded or suspected, may also, it is said, be eaten, at least in moderate quantity, without danger. They contain, however, the alkaloid *Solanine*, found also in the shoots of the potato. For the Woody Nightshade, see BITTERSWEET; for the Deadly Nightshade, see BELLADONNA; and for Enchanter's Nightshade, see CIRCEA.

Common or Black Nightshade
(*Solanum nigrum*).

Nihilism is a term used to describe various negative systems of metaphysics, ethics, and atheist philosophy. The Nihilism, or Nihilianism, of the middle ages was a heretical view of the nature of Christ. In the 19th century the name of Nihilist was applied to Russian revolutionists, and especially (though improperly) to those of the 'terrorist' wing. In *Fathers and Sons*, Turgeniev in 1862 described as Nihilists a new type among the Russian educated classes—men who bowed before no authority of any kind, and defied 'the fathers' 'to find out, in our present life, family and social, one single institution which would not deserve an absolute and pitiless negation'; and, 'abandoning all talk about art, unconscious artistic creation, parliamentarism, reformed tribunals, and what not else,' they put above all 'the question of daily bread for all,' and reformed their own lives according to truth and sincerity. Tchernyshevsky represented the Nihilists not as simple philosophers of negation, but as people engaged either in science or in social reforms, or as revolutionists; and laid stress upon their treatment of woman as an intellectually equal comrade in work. Nihilism was in its philosophical aspects an outcome of the philosophy of the 18th century as modified by modern science; Buckle, Darwin, H. Spencer, and J. S. Mill were the most popular

authors among Nihilists. But the doctrine had its roots deep in the past life of the Russian educated classes; Pushkin was already nicknamed Nihilist by his adversaries. Nihilist novelists and writers on art and politics exercised a deep influence upon the life of the educated classes in Russia, and contributed to the movement for the higher education of Russian women. The revolutionists who were described in western Europe as Nihilists or Anarchists had political programmes directly borrowed from western Europe. The Russian revolutionary movement was due to the influence of Herzen about 1860, when the hopes of thorough reforms awakened by the proposed emancipation of the serfs were frustrated by the ascendancy acquired by the serf-owners' party in the councils of the tsar. Proclamations appealing to the peasants to revolt were issued in 1861, and two secret societies were organised. The poet Mikhailov, Tchernyshevsky, and others were sent to hard labour in Siberia. When, after the Polish insurrection (1863), the old party took the upper hand in the Winter Palace a new revolutionary propaganda resulted in a peasants' outbreak at Kazan (1864). Societies organised for self-education took a revolutionary character, under the influence of Bakunin, the ideas of the International and the socialist writings of Lavrov. Young men and women of rich families abandoned their homes, and went to the villages and factories as workers, schoolmasters in villages, medical helps, midwives, and so on, either simply to share with the people their life of privation or to carry on a revolutionary propaganda. More than 2000 of them were arrested (1873-76) and kept for years in prison; some were exiled, some tried and condemned. The flogging of a prisoner in the St Petersburg prison by the prefect of police, General Trepov, moved Vera Zasulich to make an attempt upon his life (1878). When she was acquitted, trials for political offences were transferred to courts-martial; while on the other side the revolutionists, abandoning more and more the propaganda among the people, resorted to a policy of terror. They killed several spies, one police official, the governor-general of Kharkov, and the chief of the state police, and several attempts against the life of the tsar were made. A number of revolutionists were hanged and hundreds exiled to Siberia during the same twelve months (1878-79). The executive committee of the party of the 'Will of the People' prosecuted its underground work, and Alexander II. was killed by bombs (1881). Alexander III. dismissed his father's ministers and proclaimed his resolution to remain an absolute sovereign. He lived almost a prisoner in Paul I.'s palace at Gatchina, and fresh plots continued to be discovered. Nicholas II., who succeeded his father in 1894, continued his policy, and so became obnoxious to the revolutionists. The disasters of the war with Japan in 1904-5 enormously extended and deepened the discontent of all classes. In the strikes and other riotous and revolutionary demonstrations in the populous centres in the spring of 1905, Nihilism, Anarchism, and Socialism were associated with economic distress and industrial revolt. During later constitutional struggles the name of Nihilist was superseded by those of the several irreconcilable sections of the opponents of the tsarist régime.

See works by Stepniak and Kropotkin (1883-95), and works on the history of Russia (q.v.).

Niigata, a seaport of western Japan, situated on a narrow strip of land at the mouth of the Shinano River, was opened to foreign trade in 1859. The harbour did not admit of the entrance of vessels of foreign build, and the roadstead was

exposed; the foreign trade therefore long remained only nominal until improvements were made in the 20th century. The apples and water-melons of the province are noted for their excellence, and petroleum is got. Pop. 100,000.

Nijmegen. See NIMEGUEN.

Nijni-Novgorod ('Lower Novgorod'), a famous commercial city of Russia, and capital of a government, is situated at the confluence of the Oka with the Volga, 274 miles E. of Moscow by rail. It is made up of an upper city, containing the Kremlin and many of the fifty churches, a lower city, and a suburb. The great fair in normal times brings buyers and sellers from all climes between Germany and China, and is, or at least was, the greatest in the world. During the fair, the normal population (almost 100,000) is increased about fourfold. During the civil wars the Russian fairs were discontinued. The great fair of Nijni-Novgorod was started again in 1923. It runs now from 1st August to 15th September. Nijni-Novgorod, founded in 1221, was devastated on several occasions by the Tatars; its prosperity dates from the year 1817, when the great fair was removed to Nijni-Novgorod from Makarief after a great fire. A university was founded in 1918.—The government, which has an area of 30,000 sq. m. and a population of 2,600,000, produces timber, iron and iron goods, salt, copper, gypsum, wool, and leather.

Nijni-Tagilsk, a town of Russia, amid the Ural Mountains, 150 miles E. of Perm by rail, with great platinum, copper, and iron works; pop. 38,000.

Nikolaevsk, a port of eastern Siberia, 23 miles from the mouth of the Amur, was burned down in 1920; pop. 13,000. Coal is found in the district.

Nikolaiev, a port of Ukraine, at the confluence of the Ingul with the Bug, and 42 miles from the Black Sea, was the headquarters of the Russian Black Sea fleet. The joint estuary of the Bug and Dnieper was defended by the forts of Otchakoff and Kinburn; and Nikolaiev was a great fortified naval station. It has shipbuilding and engineering works, and exports grain. Pop. 70,000.

Nikolsburg (Czech *Mikulov*), a town in the south of Moravia, 27 miles S. of Brunn by rail, lies at the foot of hills famous for their rich red wines. In its midst, on a rock, stands the castle of the (till 1918) princely Dietrichstein family. It is chiefly known through the preliminary peace between Prussia and Austria (26th July 1866) and Prussia and Bavaria (28th). Pop. 8500.

Nikon (1605-87), the Russian patriarch and primate whose revision of the very incorrect Slavonic service-books caused the secession of the Raskolniks (q.v.).

Nikosia. See NICOSIA.

Nile, the longest river of Africa, if not of the world, hydrographically, historically, and geographically a river of the greatest interest, and to the ancient Egyptians pre-eminently the sacred river, draws its largest supplies of water in the country of its sources from the Victoria and Albert Nyanzas. The only important streams flowing into the Victoria Nyanza are the Kagera, Nzoia, Nyando, and several others of less importance on the east side. The largest of these, the Kagera, originates in a number of small streams rising in the mountains on the north-east shores of Tanganyika. It flows northwards, studded with a few small lakes, and finally turns eastwards and falls into the Victoria Nyanza a little north of the first degree S. lat. The Kagera is understood now to be the undoubted source of the Nile. The Nile leaves Victoria Nyanza at its northern end, pouring over the Ripon Falls, 150 to 170 yards wide but only 12

feet high, and then for 300 miles races between high rocky walls, over rapids and cataracts, at first north-west, then west, until it joins Lake Albert near its north-east corner. About 20 miles from this lake the river leaps down 120 feet into a wild gorge, with high rocky walls. The section between the two lakes is called the Victoria Nile or Somerset River. At its south-western extremity Lake Albert is joined by the river Senliki, which drains away the surplus water of Lake Edward (discovered by Stanley in 1889); and this lake in its turn drains the slopes of the snowy Ruwenzori and adjacent mountains. The combined river leaves the northern extremity of Lake Albert as the Bahr-el-Jebel, and from that point flows in a general northerly direction to the Mediterranean. The first 130 miles to Dufile it passes through a level country, and frequently expands into lakes. From Dufile to Lado (120 miles) the bed is contracted by rocky hills from a mile to a quarter of a mile in width; and the stream is forced over the Yarborah Rapids. At Lado (5° N. lat.) the river enters the plains, and

The Nile.—The First Cataract, looking down the river towards Assuan.

moves thence slowly and sluggishly down to Khartum, 900 miles to the north. From Refaj downwards the Nile is navigable for river-steamers of fairly large size. In 7½° N. lat., however, the main channel divides; whilst the right arm, the Bahr-el-Zeraf, goes almost due north, the left arm, which still continues to be called the Bahr-el-Jebel, trends slightly to the west. Both streams flow through a low swampy region, during the rainy season inundated for miles wide. The banks are lined with tall reeds and papyrus, the abode of numerous aquatic birds and swarms of gnats and other insect plagues. Since the year 1863 both channels had been rendered wholly or in part impassable by vast accumulations of vegetable débris (*sudd*), but in 1900–2 it was cleared out with a view to improving the navigation of the upper river. In 9½° N. lat. the Bahr-el-Jebel meets the Bahr-el-Ghazal, which, coming from the west, gives the united stream, now called the White Nile, an easterly course. Although this tributary, navigable for some 200 miles above the confluence, runs nearly dry in the dry season, it gathers to itself the contributions of a very large number of rivers, some of them 300 and 400 miles long, which have their sources to the south and south-west in the country of the Niam-Niam tribes; one only, the Bahr-el-Arab, comes from the northern side—from Darfur, to the north-west.

Sixty miles east of the confluence the White Nile receives the Bahr-el-Zeraf, and 30 miles farther east the navigable Sobat from the Galla country. Some 60 miles below the Sobat mouth is Kodok (Fashoda), whose occupation by Marchand in 1898 threatened to bring war between France and England. From Kodok the White Nile flows almost directly north to Khartum without being augmented by a single tributary stream. At Khartum (in 15° 37' N. lat.) the White Nile, or Bahr-el-Abiad, is joined from the south-east by the Blue Nile, the Bahr-el-Azrak, the water of the respective streams being of the colour indicated in the names. The Blue Nile, 950 miles long, gathers its volume principally from Lake Tzana (5658 feet above sea-level), situated on the Abyssinian plateau, in which region it is known as the Abai. It leaves the lake towards its southern end, and, after running south-east, curves right round by way of the south till it comes to flow north-west. After leaving the mountains it traverses an extremely fertile plain, the capital of which is Sennaar. From Khartum the Nile flows north-north-east, and 200 miles below that city is joined from the right by the Atbara, called also the Bahr-el-Aswad, or Black Nile. It is the black sediment brought down by this river that settles in the Nile delta, and makes it so extraordinary fertile. This affluent, too, has its source on the Abyssinian plateau, and its volume is increased by two large tributaries, the Takazze and Mareb, both striking into it from the right. During its course from the confluence of the Atbara through the Nubian Desert the great river makes two deep bends, first round by the north, then round by the south, and subsequently resumes its northerly flow. Below Khartum navigation is rendered extremely dangerous by the cataracts which obstruct the bed of the river, the sixth occurring not far north of Khartum, the first near Assuan, in Egypt, just beyond 24° N. lat. The

course of the river from Assuan to the sea is sufficiently described under Egypt (q.v.). The total length of the river cannot be stated precisely; from Lake Victoria it is estimated to measure 3400 miles. The Nile begins to rise at Gondokoro in April, the Bahr-el-Ghazal perhaps a week or two earlier. At Khartum the rise begins in May, and reaches its maximum in September, whilst the Blue Nile rises from July to the third week in August (see NILOMETER). Irrigation is largely regulated by barrages at Rosetta and Damietta, constructed by French engineers in 1843–61, and practically reconstructed in 1886–90. A vast reservoir was completed in 1912 at Assuan (q.v.; and see also PHILÆ); the Blue Nile was dammed in 1914–25 at Makwar (see GEZIRA); and similar works on the White Nile have been partly carried out (see GEBEL AULIA).

The ancients had little knowledge of the Nile above Meroe, between Berber and Khartum. The place of accurate knowledge was taken by myth, to the effect that the river had its origin in Mauretania (now Morocco), and flowed several days' journey underground until it came to the south of Ethiopia; thence it passed northwards as the Astapus. The Emperor Nero began the fascinating work of searching for the sources of the Nile by sending two expeditions, which seem to have ascended beyond the confluence of the

Sobat and White Nile. Ptolemy speaks of two streams issuing from two lakes 6 and 7 degrees south of the equator and uniting in 2° N. lat., and being joined in 12° N. lat. by the Astapus, which likewise flowed from a lake (Coloe). The two lakes in the far south were fed by the melting snows of a great range of mountains, the Mountains of the Moon (which Stanley identified with Ruwenzori, Gordon Bennett, and the adjoining peaks). This remained the sum total of information about the river down to the 19th century, except that in 1770 Bruce discovered that the Blue Nile issued from Lake Tana. The Egyptian government in the years 1839-42 sent three expeditions up the river, which got as far as Gondokoro. In 1858 Speke reached Lake Victoria, and in 1862 discovered Ripon Falls. Two years later Sir Samuel Baker discovered Lake Albert, and in 1868-71 Schweinfurth explored the western feeders of the White Nile. Stanley, in 1875, sailed all round Lake Victoria, and in 1889 traced the course of the Semliki, and discovered Lake Edward or (Albert) Edward Nyanza, and Mount Ruwenzori.

See works of the explorers named, also others by Marno, Von Klöden, Wilson and Felkin, Schuber, Petherick, Junker, &c.; Sir H. H. Johnson's *Nile Quest* (1903); and Captain Lyons's *Physiography of the River Nile* (1906). For the battle of the Nile, see ABOUKIR.

Nilgiri. See NEILGHERRY.

Nilometer, an arrangement for measuring the height of the Nile in Egypt. On the island of Rhoda, opposite to Cairo, is a square well, connected with the river by a canal, and containing a graduated marble pillar, divided into 24 cubits, each measuring 21·386 inches. A rise of 18 cubits is traditionally regarded as the height of the lowest inundation; 19 cubits is considered tolerable, 20 excellent, 21 adequate, and 22 complete, but 24 is ruinous. The ordinary maximum of the rise at Cairo is stated at from 24 to 26 feet. For the inundations from 1849 to 1878, see *Nature*, vol. xxv. The nilometer of Rhoda was constructed during the reign of the khalif Al-Mutawakkil, in the year 847. Anciently there seem to have been various nilometers of different kinds, all along the river, as at Memphis (probably the oldest), Ekhmin, Elephantine, and elsewhere.

Nilsson, CHRISTINE, was born the daughter of a farmer at Sjöabel near Wexiö, in Sweden, 20th August 1843, and singing at a fair in 1857 so impressed a magistrate of Ljungby that he sent her for a musical education to Stockholm and Paris. She made her début at Paris in *La Traviata* in 1864; and in London, where she appeared in 1867, soon took rank as one of the foremost soprano singers. Marguerite was one of her best-known parts. She married (1872) M. Rouzaud (d. 1882), and (1887) Count de Miranda (d. 1902). She died 22d November 1921.

Nimach, a town of India, in the territory of Gwalior, on the north-western border of Malwar 370 miles SW. of Delhi by rail, 1613 feet above sea-level, with an agreeable and healthy climate. There has been a British cantonment there since 1817. Pop. of town, 3900; of cantonment, 10,500.

Nimbus, in Art, especially in sacred art, is the name given to the disc or halo which encircles the head of the sacred personage who is represented. Its use is almost universal in those religions of which we possess any artistic remains—the Indian, the Egyptian, the Etruscan, the Greek, and the Roman. Some, indeed, have sought directly to derive it from the Greek *mēniskos*, or metal disc placed over the heads of statues to keep off the droppings of birds. Nevertheless, the nimbus, strictly so called, is comparatively recent in Christian art, not appearing before the 6th century. Later

in Christian art it became almost a necessary appendage of all representations of God or of the saints. Its ordinary form is the circular or semi-circular; but the nimbus of the Eternal Father is often in the form of a triangle, and that of the Trinity an emanation of light, the rays of which form the three arms of a cross. The nimbus of the Virgin is sometimes a simple ring, and sometimes a crown or diadem; occasionally it is encircled by an ornamental border, on which twelve stars are sometimes represented. Her nimbus, as well as that of the Divine Persons, is commonly of gold; but occasionally it is in colours, as blue, red, purple, or white. The nimbus of the saints is ordinarily the semicircle or lunula. In later art the nimbus became lighter and more aerial, melting, as it were, into the picture. In connection with the nimbus may also be mentioned the *Aureole*, an illumination surrounding, not the head only, but the entire figure. If the figure be upright the aureole is commonly oval, when it is called the *vesica piscis*, and is supposed to contain an allusion to the sacred Christian emblem, the *ichthys*. With a seated figure it becomes circular, and is occasionally divided by radiating bands, in the form of a wheel; sometimes it takes a quatrefoil form. It is commonly of gold, but occasionally also is in colours. The *Glory* is a combination of the nimbus and the aureole, and is chiefly seen in Byzantine pictures and those of the early South German school.

Nimeguen (Dutch *Nijmegen*), a town of Holland, in the province of Guelderland, on the left bank of the Waal, 73 miles by rail E. of Rotterdam. It is built on the slope of the Hoenderberg ('Hill of the Huns'), on which the Romans formed the permanent camp of *Noviomagus*; and some of its streets are steep and narrow, but others are broad and handsome. On a neighbouring height stood till 1796 a castle, said to have been founded by Caesar and inhabited by Charlemagne; and towards the brow of this height there still stands a little sixteen-sided Romanesque baptistery of the 12th or 13th century. On another eminence is the modern Belvedere, whose summit commands a wide view. The fortifications have been demolished; but Nimeguen retains its Renaissance town-hall (1544), adorned with medallions of German emperors, and the fine Gothic church of St Stephen (dating from 1272). The manufactures include tobacco, eau de Cologne, metal-work, beer, &c. Pop. (1875) 22,929; (1923) 71,514. Regained by the Spaniards (1585-91), Nimeguen is celebrated in history for its great peace congress, which on 12th August 1678 concluded a treaty between France and Holland, on 13th December between France and Spain, and on 5th February 1679 between Austria and France.

Nîmes, the capital of the French department of Gard, lies in a fertile plain, engirt by the vine-clad Cevennes, 31 miles by rail NE. of Montpellier and 30 SW. of Avignon. The old town, with narrow crooked streets, is separated by shady boulevards from the well-built faubourgs; and mediæval and modern edifices are a much mutilated cathedral, the prison (formerly citadel, 1687), the palais de justice, St Paul's (1850), St Baudile's (1875), &c., with a most magnificent fountain, and a monument (1874) to Antoninus Pius. But the glory of Nîmes is its Roman remains of the ancient *Nemausus*. These include the 'Maison Carrée' (now a museum, with Delaroche's masterpiece, 'Cromwell looking on Charles I.'s corpse'), a splendid specimen of Corinthian architecture; an amphitheatre (now a bull-arena), 70 feet high, and seating 20,000 spectators; the exquisite Nymphæum; a mausoleum ('La Tour Magne'), baths, and two gates,

whilst 14 miles NE. is the 'Pont du Gard,' most perfect of Aqueducts (q.v.). Nîmes is a seat of great commerce and manufactures, these comprising silk and cotton goods, carpets, shawls, wine, brandy, boots, &c. Pop. (1872) 60,020; (1921) 82,774, of whom one-third are Protestants. Supposed to have been colonised from *Massilia* (Marseilles), and the capital of the *Volcæ Arecomici*, Nîmes flourished under the Romans, and was one of the great cities of Gaul. It was taken by the Visigoths (465), the Franks (507), and the Saracens (725), and subsequently became an appanage of Aragon, but was finally restored to France by the treaty of Corbeil (1259). The inhabitants adopted Calvinism in the 16th century; and it was a stronghold of the Camisards (q.v.). In 1791 and 1815 it was the scene of bloody religious and political reactions. Nicot, Guizot, and Daudet were natives.

Nimrod. See BABYLONIA, BABEL; as a *nom de guerre*, see APPERLEY.

Nine Eyes, a popular name for the young lampreys found in rivers. See LAMPREY.

Nineveh, the modern *Kuyunjik*, capital of the ancient kingdom of Assyria. Its original capital was Assur, the ruins of which are now called *Kalaat Sherghat*; but the group of cities some sixty miles to the north, above the Greater Zab, and on the eastern side of the Tigris, namely Nineveh, Kalakh (*Nimrâd*), and Dur-Sargon (*Khorsabad*), ultimately supplanted it in importance. When Nineveh itself fell, the whole Assyrian empire—essentially a military power—perished with it. In the Sassanian period a village was built on the mounds which covered its ruins; but when its buildings had also crumbled into ruins, the very site of the proud ancient city remained for centuries unknown. Rich in 1818 conjectured that the mounds of Kuyunjik, opposite the modern town of Mosul, concealed its ruins beneath, but it was not until the excavations of Botta in 1842 and Layard in 1845 that the remains, first of Dur-Sargon, then of Nineveh itself, were revealed to the world. The sculptured monuments of its ancient kings and the relics of its clay-inscribed library soon yielded up their secrets to the investigations of scholars, and ere long the life and history of the ancient kingdom of Assyria were known almost with as much certainty as those of Greece and Rome. See ASSYRIA, and CUNEIFORM INSCRIPTIONS.

Ning-po, a treaty-port of the Chinese province of Che-keang, stands in a fertile plain, 16 miles from the mouth of the Takia (Ning-po) River and about 100 miles S. of Shanghai. It is surrounded by a wall 25 feet high and 16 feet thick, and contains numerous temples, colleges, &c., chief amongst them the temple of the Queen of Heaven; the temple was founded in the 12th century, but the present building, elaborately and richly ornamented, dates from 1680. The people, 670,000 in number, make sedge hats and mats, grow cotton, catch cuttle-fish, and carry on an active trade, especially in the export of green tea. Ning-po is a great mission station.

Ninian, St, the first known apostle of Scotland, was born of noble parentage, about 360, on the shores of the Solway Firth. Of studious and ascetic habits, he was moved by the Holy Spirit to make a pilgrimage to Rome, and there, after some years' stay, was consecrated bishop by the pope. On his homeward way he visited St Martin (q.v.) at Tours, and after his arrival in Galloway he founded the 'Candida Casa,' or church of Whithorn, dedicating it to St Martin, the news of whose death had just reached him (397). Later he laboured successfully for the evangelisation of the Southern Picts,

and in 432 (according to the Bollandists) died 'perfect in life and full of years,' and was buried in his church at Whithorn. His festival falls on 10th September. His Life by St Ailred (1109–66), abbot of Rievaulx in Yorkshire, who visited Galloway, has been edited by Bishop Forbes (1874), who enumerates sixty-six dedications in Scotland to St Ninian or 'Ringan'—the Lowland Scots form of his name—including the Episcopal cathedral at Perth.

Ninon. See LENCLOS.

Niobe, in Greek Mythology, the daughter of Tantalus and wife of Amphion, king of Thebes, to whom she bore six sons and six daughters. Proud of her children, she despised Leto or Latona, who had only two children, Apollo and Artemis; whereupon Latona, enraged at her presumption, moved her children to destroy all the children of Niobe with their arrows. They lay nine days in their blood unburied, when Zeus changed them into stone, and on the tenth day they were buried by the gods themselves. Niobe was changed into stone on Mount Sipylus, in Lydia, from which tears flowed every summer. Such is the Homeric legend, which, however, was afterwards much varied and enlarged. Only fragments exist of the tragedies of Æschylus and Sophocles on this theme, which was a favourite subject of ancient art. The so-called Niobe on Mount Sipylus is probably Hittite work. A noble group representing Niobe and her children was discovered at Rome in 1583, and is now in the Uffizi Palace at Florence. Even the ancient Romans were in doubt whether the work proceeded from Scopas or Praxiteles.

Niobium (sym. Nb; atom. number 41; equiv. 93.1) is a rare metal discovered by H. Rose in the mineral *Tantalite*. It may be obtained by passing the vapour of the chloride along with hydrogen through a red-hot tube. It is of a steel-gray colour, specific gravity 4.06, and takes fire when heated in the air or in chlorine gas. It is but little acted on by hydrochloric or nitric acid, but is soluble in strong sulphuric acid. It forms compounds with oxygen, chlorine, sulphur, &c., but these are of little practical importance.

Niort, the capital of the French department of Deux-Sèvres, pleasantly situated on the navigable Sèvre Niortaise, 43 miles NE. of La Rochelle and 109 SW. of Tours. An important railway junction, it has an old castle, an hôtel-de-ville (1530), a fine public garden, and the 16th-century church of Notre Dame, with a spire 246 feet high. The dressing of leather and the manufacture of gloves are the leading industries. Pop. (1921) 23,559. Niort in the 14th century was held for eighteen years by the English. It was the birthplace of Madame de Maintenon.

Nipa, an Old World 'stemless palm' (*Nipa fruticans*), grows in brackish swamps. The sap yields alcohol and sugar.

Nipigon, a lake of Ontario, 30 miles NW. of Lake Superior, with which it is connected by the Nipigon River. It is about 70 miles long, but its deeply-indented coast-line measures 580 miles. Its greatest depth is 540 feet. The lake is studded with hundreds of islands.

Nipissing, a lake of Ontario, north-east of Lake Huron, into which (Georgian Bay) it drains through French River (55 miles). It measures 50 by 28 miles, and is 644 feet above sea-level.

Nippon. See JAPAN.

Nippur, one of the oldest cities of Babylonia (q.v.).

Nirvāna. See BUDDHISM.

Nish (Serb. *Niš*), the chief town and commercial and railway centre of middle Serbia,

stands in mud in the midst of a vine-growing district, 152 miles by rail S.E. of Belgrade. It is the seat of a Greek bishop, and has a fairly strong citadel (1737). The place has played a conspicuous part in the Turkish wars from 1375 down to 1878, when it was regained by Serbia. Here, on 23d September 1689, the Austrians defeated the Turks. On the outbreak of war in 1914 the Serbian government was transferred at first to Nish, which was taken by the Bulgars in November 1915. Pop. 25,000.

Nishapur, a town of the Persian province of Khorasan, 53 miles W. of Meshhed, in a beautiful and fertile valley, has 20,000 inhabitants and a trade in turquoises. It was the birthplace, and contains the grave, of Omar Khayyám.

Nisibis, the capital of ancient Mygdonia, was a city of great antiquity, important as a place of strength and as an emporium of trade between east and west. It was twice taken by the Romans (under Lucullus and Trajan), and again given up by them to the Armenians; but being a third time taken, in 165 A.D., it remained the chief bulwark of the Roman empire against the Persians, till it was surrendered to them after the death of Julian in 363. The name *Nisibin* is retained by a small village on the Bagdad railway and the Syrian frontier of 1921, round which are numerous remains of the ancient city.

Nisi prius is the name (borrowed from the first two words of the old writ which summoned juries) usually given in England to the sittings of juries in civil cases. Thus, a judge sitting at *nisi prius* means a judge presiding at a jury trial in a civil cause, and a *nisi prius* lawyer is one who devotes himself to jury practice.—For the decree *nisi*, see DIVORCE.

Nith, a beautiful Scottish river, rising in Ayrshire, and flowing 71 miles south-south-eastward (mainly through Dumfriesshire), until, 14 miles below Dumfries, its estuary joins the Solway Firth.

Nithsdale, WILLIAM MAXWELL, EARL OF, was born in 1676, and at seven succeeded his father as fifth earl. In 1699 he married at Paris Lady Winifred Herbert (c. 1679–1749), youngest daughter of the Marquis of Powis, and thenceforward lived almost constantly at his Kirkcudbrightshire seat, Terregles, much embarrassed in circumstances, and sorely troubled as a Catholic by the neighbouring Presbyterian ministers. In 1715 'Nithsdale's bonnie lord' at once joined the English Jacobites under Forster and Derwentwater, and was taken prisoner at Preston. He was tried for high-treason in London, and sentenced to death in spite of abject excuses; but on 23d February 1716—the night before the day fixed for his execution—not knowing he had just been reprieved, he escaped from the Tower in woman's apparel, through the heroism of his countess. Naturally delicate and then advanced in pregnancy, she had ridden up to London in the depth of winter; and after her lord's escape she came back to Terregles, and dug up the family deeds, which she had buried in the garden, and by one of which the estates had been disposed in 1712 to their only son. They now settled at Rome, where the earl died on 20th March 1744. See Sir W. Fraser's *Book of Carlaverock* (2 vols. 1873).

Nitrates. See NITRE, NITRIC ACID, NITRIFICATION, MANURE.

Nitre, or SALTPETRE (Lat. *sal petrae*, 'salt of the rock,' through Old French), is potassium nitrate, KNO_3 . It usually occurs in long, colourless, striated, six-sided prisms; its taste is cooling, and very saline; it is soluble in seven times its weight of water at 60° (15.5° C.), and in less than one-third of its weight of boiling water, but is

insoluble in alcohol. When heated to about 660° (348° C.) it fuses without decomposition into a thin liquid, which, when cast in moulds, solidifies into a white, fibrous, translucent mass, known as *sal prunelle*. At a higher temperature part of the oxygen is evolved, and potassium nitrite is formed. Owing to the facility with which nitre parts with its oxygen, it is much employed as an oxidising agent. Mixtures of nitre and carbon, or of nitre and sulphur, or of nitre, carbon, and sulphur, deflagrate on the application of heat with great energy; and if nitre be thrown on glowing coals it produces a brisk scintillation. *Touch-paper* is formed by dipping paper in a solution of nitre, and drying it.

Nitre occurs as a natural product in India and Persia, where it is found sometimes as an efflorescence upon the soil, and sometimes disseminated through its upper stratum. The crude salt is obtained by lixiviating the soil, and allowing the solution to crystallise. The occurrence of nitre in this situation is commonly the result of the natural decay, with the aid of atmospheric oxygen, of nitrogenous animal matters in presence of the ash from wood fires (which supplies the requisite potassium in the form of carbonate), and it depends upon the vital activities of several organisms (nitrifying bacteria, see NITRIFICATION). Much nitre used to be artificially formed in Europe by imitating the conditions under which it is naturally produced. Animal matter, mingled with ashes and lime rubbish, is placed in loosely aggregated heaps, exposed to the air, but sheltered from rain. The heaps are watered from time to time with urine or stable runnings; at suitable intervals the earth is lixiviated, and the salt crystallised. As there is always present a considerable quantity of calcium and magnesium nitrates which will not crystallise, potassium carbonate in the shape of wood ash is added so long as any precipitation of calcium and magnesium carbonates occurs. The potassium nitrate formed remains dissolved. The clear liquor is then evaporated and the nitre crystallised.

The bulk of the nitre of commerce is now made from Chile nitre (sodium nitrate, see below) by interaction with potassium chloride from the Stassfurt deposits. The operation is carried on in aqueous solution at an elevated temperature, such that, while the greater part of the less soluble sodium chloride produced by the interaction separates and can be removed in the solid form, most of the potassium nitrate remains in the solution, and can be recovered from this by evaporation and crystallisation.

Nitre is employed as an oxidising agent in various chemical processes, as an ingredient in making fireworks, and especially in the manufacture of Gunpowder (q.v.). Its place in the manufacture of sulphuric and nitric acids has now been taken largely by the cheaper sodium nitrate (see below). It is used, further, in pickling meat and has various applications in medicine. In moderate doses (from five to twenty grains) it acts as a diuretic and diaphoretic, but the acetate or citrate of potassium is preferable for this purpose, and nitre is now seldom used for internal administration. It is a popular remedy in sore throat, in the form of nitre balls, which should be retained in the mouth till it melts, and the saliva impregnated with it gently swallowed. The inhalation of the fumes produced by the ignition of *touch-paper* often gives speedy relief in cases of spasmodic asthma.

Cubic Nitre, or *Chile Nitre*, is sodium nitrate, NaNO_3 . It occurs in enormous deposits in association with common salt (sodium chloride), gypsum, and earthy matters at or near the surface of the

soil in almost rainless desert regions of Chile—especially Atacama and Tarapacá. The natural deposit is known as *caliche*, and it may contain 60 per cent. or more of sodium nitrate with as much as 25 per cent. of common salt. To separate the sodium nitrate from its less soluble or insoluble accompaniments the crushed *caliche* is lixiviated with boiling water, the solution being eventually made as concentrated as possible at the temperature employed, which is 248° (120° C). As this solution cools, sodium nitrate crystallises out and is separated from the mother liquor, which is used over again for extracting further quantities of *caliche*. The crystallised nitre, after drying in the air, is packed in sacks for transportation. It contains about 95 per cent. of sodium nitrate with about 2 per cent. of sodium chloride and some other impurities. When purified by re-crystallisation from aqueous solution, sodium nitrate forms cube-like rhombohedra, whence its name cubic nitre, although the crystals are not true cubes. In most of its properties it resembles ordinary nitre, but in consequence of its deliquescent nature it cannot be employed instead of that salt in the preparation of gunpowder, since the latter would tend to become damp. Being much cheaper than potassium nitrate, the sodium salt is now employed in the manufacture of sulphuric and nitric acids. Very large quantities of the salt as exported from Chile now find application as nitrogenous fertilising material in agriculture, the export having in some recent years approximated to three million tons. See CHILE, and books there cited. For Sweet Spirits of Nitre, see NITROUS ETHER.

Nitrian Desert. See NATRON LAKES.

Nitric Acid (HNO_3). This acid—the *aqua fortis* of the older chemical philosophers—may be regarded as the most important of all the compounds of nitrogen, its applications in the arts, in manufactures, and in chemical processes being very extensive. It has been known from very early times, its production being described by Geber, in the 8th century, by the distillation of nitre with copper sulphate and alum, the water of crystallisation of these salts furnishing the hydrogen, which is a constituent element of the resulting acid. It was Glauber, in the 17th century, however, who first prepared it by distilling nitre with oil of vitriol (sulphuric acid).

In the earlier manufacture of the acid by the distillation of a nitrate with sulphuric acid, ordinary nitre (potassium nitrate) was used, but the much cheaper cubic nitre (sodium nitrate) is now almost universally employed instead. In the modern operation the sodium nitrate and sulphuric acid are introduced into cast-iron retorts, and the nitric acid formed by their interaction is distilled off at a temperature which, at first, does not reach that of boiling-water, but which rises as the operation proceeds. The vapours arising during the distillation are passed into water-cooled condensing apparatus of silica or of an iron-silicon alloy, and the condensed acid is collected in earthenware, lead, or silicon-iron alloy receivers.

In the interaction between the cubic nitre and the sulphuric acid, the hydrogen of the acid may be regarded as capable of displacement in two stages, such that the quantity of the nitre required for the first stage is just one-half of that required to complete both stages. This is illustrated by the following equations:

It is not economically satisfactory, however, to carry on the reaction to the completion of the second stage, since this requires a considerably higher temperature than that necessary for the first stage, and instead of much of the nitric acid there would be obtained the products of its decomposition, viz. water, nitrogen peroxide, and oxygen:

Even at the lower temperature at which the first stage takes place, decomposition of the nitric acid occurs to a slight extent in the sense represented above, and its occurrence can be recognised when the operation is carried out in a glass retort by the yellowish colour of the vapour in the retort due to the nitrogen peroxide which is produced.

In actual manufacturing practice, the quantities of the materials are so adjusted that there is more sodium nitrate than is required for the first stage only, but not nearly enough to complete the second also, and the temperature is not permitted to rise too high. The material left in the retorts after the removal of the nitric acid by distillation is mainly a mixture of sodium hydrogen sulphate with a certain proportion of sodium sulphate. It is liquid while hot and can be run off from the retorts, but on cooling it solidifies, and in this condition is known as 'nitre cake.' It can be made use of in the production of sodium sulphate, the sodium hydrogen sulphate which it contains being converted into sodium sulphate by interaction with sodium chloride, and hydrochloric acid being liberated during this change:

The nitric acid obtained in the process outlined above contains a small proportion of water and is yellow in colour owing to the presence of dissolved nitrogen peroxide. The water can be almost completely separated by mixing the acid with concentrated sulphuric acid and re-distilling at as low a temperature as possible, and the nitrogen peroxide can be removed by blowing dry air through the heated acid. The resulting acid is a nearly colourless liquid which fumes in moist air, possesses specific gravity 1.52, and boils, with slight decomposition, at 187° (86° C). It is a highly corrosive substance, vigorously attacking animal and vegetable tissues, and dissolving many metals and other inorganic substances. Its activities may conveniently be referred to more than one class of chemical change. In the first place it acts as a strong acid, i.e. an acid in which the usual characteristics of acids (see ACIDS) are strongly exhibited. Its employment in the formation of various nitrates by its interaction with oxides, hydroxides, carbonates, &c., depends upon its character as an acid. Then it acts as a vigorous oxidising agent, since it readily yields up part of its oxygen to substances which tend to combine with this element, and is itself reduced thereby to one or more of the lower oxides of nitrogen, such changes being frequently accompanied by the evolution of brown fumes of nitrogen peroxide. The oxidising effect of nitric acid is illustrated by its action on various metals, whereby nitrates are produced and a part of the nitric acid is simultaneously reduced. A further type of action is illustrated in the formation of the so-called nitro-substitution compounds such as Nitrobenzene (q.v.) and tri-nitrotoluene, in which one or more nitro-groups, NO_2 , may be substituted for one or more hydrogen atoms. In connection with the nitro-substitution compounds it may prevent confusion to note that the explosive substances known as nitro-glycerine and nitro-cellulose (gun-cotton) are not nitro-compounds in the sense here stated but are really nitrates. During the period of the Great War, the production

of nitric acid was carried on upon an enormous scale for the manufacture of tri-nitrotoluene (T.N.T.) and other nitro-compounds as well as for that of nitro-glycerine, gun-cotton, ammonium nitrate, &c., to be used as explosives.

It has been known since the experiments of Cavendish, in 1785, that when electric sparks are passed through moist air, or any other mixture of nitrogen and oxygen in presence of water vapour, nitric acid is produced. A similar combination on a larger scale takes place naturally during thunderstorms, and the occurrence of this is manifested by the carrying down of traces of dissolved nitrates in rain. Since 1905 processes have been devised and successfully carried out on the manufacturing scale in which atmospheric nitrogen and oxygen are employed in the synthetic production of nitric acid by aid of electricity. (See NITROGEN.)

Another modern mode for preparing synthetic nitric acid depends upon the oxidation of ammonia, the latter being itself obtained as a product of the direct combination of nitrogen with hydrogen. Under appropriate temperature conditions and in presence of a suitable catalyst, such as platinum wire gauze, ammonia in intermixture with air undergoes oxidation to form nitric oxide (see NITROGEN), and from this nitric acid can be obtained.

When the hydrogen of nitric acid is replaced by a metallic or other radical, a nitrate is formed. The nitrates of the metals are mostly soluble in water. Important inorganic nitrates are ordinary nitre or saltpetre (potassium nitrate), cubic nitre or Chile saltpetre (sodium nitrate), ammonium nitrate, and silver nitrate. The last named, when fused and cast into thin sticks, is known as lunar caustic.

'Fuming nitric acid' is an orange-brown strongly fuming liquid which consists of concentrated nitric acid containing a considerable quantity of dissolved nitrogen peroxide. It acts as a more vigorous oxidising agent than pure nitric acid.

Nitrification is the term applied to the oxidation by bacteria of ammonium salts to nitric acid. It takes place in two stages. First the ammonium salt is oxidised to nitrous acid. Accumulation of nitrous acid, however, rapidly inhibits the growth of the organism which produces it. Very little oxidation, therefore, takes place unless a substance capable of neutralising the acid formed is present. The second stage in the process is the conversion of the nitrite, formed as described, to nitrate. Each stage is due to the activity of its own particular type of micro-organism. Nitrification plays a considerable part in the purification of sewage and in the series of chemical changes which are responsible for rendering available for plant nutrition the nitrogenous substances present in soils.

The nitrifying bacteria require sources of carbon, nitrogen, and the other elements which compose their cell substance. The great majority of bacteria obtain their carbon and nitrogen from organic compounds. The nitrifying bacteria, however, are rather exceptional in that they are unable to utilise organic compounds and obtain both carbon and nitrogen from purely inorganic sources. Soluble organic substances are, in fact, highly injurious to these organisms. They completely inhibit growth when they are present in considerable concentration in nutrient solutions otherwise suitable to the activities of the organisms. For example, 0.2 to 0.3 per cent. of dextrose is sufficient to inhibit growth of the nitrifying bacteria under these conditions. In the media in which the organisms occur in nature (sewage and soil) organic compounds are not nearly so injurious as they are in culture solutions.

The oxidation of ammonium salts and nitrites respectively is the means by which the two groups of the nitrifying organisms obtain the energy necessary for their vital activities. The nitrogen necessary for building up cell substance is obtained from the nitrogenous compounds oxidised. The nitrogen requirements of the organisms for nutritional purposes (as distinct from energy-yielding purposes) are very small. On the completion of nitrification, therefore, very little of the nitrogen supplied remains locked up in the body substance of the bacteria. Under favourable conditions almost the whole of the ammoniacal nitrogen originally present in the medium is oxidised to nitrate. To allow of active nitrification ammonium salts and nitrites must be present in comparatively low concentration. The optimum concentration of both of these substances is about one part per thousand of solution. When the concentration is increased above this level nitrification is retarded and finally inhibited. Ammonium salts are not so injurious as free ammonia; 0.015 per cent. of free ammonia will completely inhibit the growth of the organism which oxidises nitrite to nitrate. The nitrifying bacteria obtain their carbon from carbon dioxide. They refuse to grow in an atmosphere entirely free from this gas.

The optimum reaction for the growth of the nitrifying bacteria is one of neutrality or very slight alkalinity. In culture solutions the organisms are highly sensitive to the presence of acid. It would appear, however, that they are less sensitive to acidity in soil than in solution cultures, as nitrification has been frequently observed to take place in distinctly acid soils. Insoluble carbonates like calcium carbonate are particularly suitable for neutralising the acid formed by the bacteria and so promoting nitrification.

Winogradsky, who first cultivated the nitrifying bacteria in pure culture, i.e. free from other organisms, gave the generic names *Nitrosomonas* and *Nitrosococcus* to the forms which oxidise ammonium salts to nitrous acid. The former appears as a short, plump rod, and is motile at one period in its development; the latter is a spherical, non-motile organism. The organism which oxidises nitrite to nitrate was named *Nitrobacter*. It is smaller than the others, pear-shaped, and non-motile. Owing to the fact that the nitrifying bacteria are sensitive to the presence of soluble organic substances they refuse to grow on the ordinary bacteriological media. The most suitable media for their growth are silicic acid gels containing an ammonium salt (for *Nitrosomonas* and *Nitrosococcus*) and a nitrite (for *Nitrobacter*), along with other suitable inorganic nutrient salts. On this medium small brownish granular growths are produced, which in the case of *Nitrosomonas* are surrounded by less dense zones consisting of small numbers of bacterial cells which have migrated a short distance from the original colony.

In the purification of sewage the material is generally first placed in deep tanks, where organic compounds are broken down by bacterial action. A large proportion of the organic nitrogenous substance in the sewage is thus converted to ammonium salts. The liquid is then allowed to flow over special filters, where it is strongly aerated. The conditions obtaining on the filters favour the activity of the nitrifying bacteria, which rapidly oxidise the ammonium salts to nitrates.

In soil the nitrifying bacteria perform a very important function in connection with the nutrition of plants. Most plants prefer to take up their supply of nitrogen from the soil in the form of nitrates. The nitrogen of plant and animal remains along with that of organic nitrogenous manures applied to the soil is first converted to ammonium

salts by certain groups of soil bacteria. The ammonium salts so formed, as well as ammoniacal nitrogen supplied in the form of fertilisers like sulphate of ammonia, are then oxidised by the nitrifying bacteria to nitrates. It is thus essential that the condition of the soil should be such that it favours the activity of these organisms. Adequate aeration is necessary to supply oxygen for the oxidation. This is secured by drainage, which removes superfluous moisture and prevents it from filling up the spaces between the soil particles and so excluding air, and by cultivation, which breaks up and aerates the soil. An adequate supply of lime to neutralise the acid formed is also desirable.

Nitro-benzene, $C_6H_5NO_2$, is a yellow, oily fluid, of sp. gr. 1.2, which may be distilled without decomposition, and boils at 415° (213° C.). It has a sweet taste, is insoluble in water, but dissolves freely in alcohol and ether. Its odour is very similar to that of oil of bitter almonds, which has led to its use in perfumery under the name of *Essence of Mirbane*. It is obtained by treating benzene, C_6H_6 , with warm fuming nitric acid, when one atom of hydrogen is replaced by the group of atoms NO_2 , so that the benzene, C_6H_6H , becomes converted into nitro-benzene, $C_6H_5NO_2$. The vapour of nitro-benzene when inhaled produces, after from 6 to 12 hours, coma and sometimes death. The fact that its action is so long delayed seems to indicate that its poisonous action is due to some product of its decomposition rather than to itself. In cases of poisoning artificial respiration and powerful stimulants should be resorted to.

Nitrogen (Fr. *azote*; sym. N; atom. wt. 14.01; atom. number 7) is an elementary gas, which in the free state forms nearly four-fifths by volume of our atmosphere. In combination with other elements nitrogen is a necessary constituent of every organised body, and it forms a very large number of most important compounds. For its relation to that gas, see ARGON. Its name was given to it shortly after it had been proved to be an essential constituent of nitre or potassium nitrate. Its presence in the atmosphere was discovered in 1772 by Rutherford, at that time a professor of botany in the university of Edinburgh. It was more particularly investigated soon after by Priestley, Scheele, and Lavoisier. It is a colourless, tasteless, inodorous gas, and was formerly regarded as permanent or incondensable; but it can be reduced to the liquid state by the application of sufficient pressure after it has been cooled to a very low temperature. The Critical Temperature (q.v.) of nitrogen, or the point of temperature above which it cannot be condensed into a liquid by the application of any pressure however great, is -149° C. When cooled to this temperature a pressure of 27.5 atmospheres must be applied in order to liquefy it.

Nitrogen is fourteen times as heavy as hydrogen, and is slightly lighter, bulk for bulk, than atmospheric air, its sp. gr. being 0.9713, compared with air = 1. It is but slightly soluble in water, one hundred volumes of water at ordinary temperatures dissolving only about one and a half volumes of it.

Whilst nitrogen is a constituent of all plant and animal organisms and of many important compounds, it is rather inert towards other elements, and, under ordinary circumstances, does not readily enter into direct combination with them. Atmospheric nitrogen and oxygen unite, however, to some extent during thunderstorms, in the immediate vicinity of lightning flashes, to form nitric oxide, and methods have been devised for bringing this union about, by aid of electricity, as a step in the synthetic production of calcium nitrate (see *Nitro-*

gen Peroxide, below). Nitrogen is not combustible, nor does it act in the atmosphere as a supporter of combustion, a lighted taper plunged into a jar containing nitrogen being at once extinguished. It is almost unnecessary to say that nitrogen is not poisonous, since it is breathed freely along with oxygen by all animals; but it cannot support animal life, and an animal placed in it will die from suffocation for want of the oxygen necessary for respiration. Its function in the atmosphere seems to be mainly that of diluting the oxygen with which it is there associated. Although nitrogen forms about 79.1 per cent. of the total volume and 77 per cent. of the total weight of the atmosphere, the free gas does not appear to play any important part in supplying nitrogen for the construction of the tissues of plants in general. It has been proved by experiment, however, that leguminous plants, in association (SYMBIOSIS, q.v.) with certain micro-organisms present in nodules which become developed upon the roots of those plants, do derive nitrogen from the air and accumulate combined nitrogen in their tissues largely in excess of the quantity originally present in the seed and the soil. To a small extent free atmospheric nitrogen becomes converted by the aid of micro-organisms present in the soil into nitrogen compounds capable of serving there as plant food. On the other hand, it has been conclusively shown that certain plants are unable to exist unless appropriate compounds of nitrogen are supplied to them in the soil in which they grow. The main supply of the nitrogen of plants is certainly drawn from nitrogen compounds existing in or artificially supplied to the soil. The most important of such nitrogen compounds are nitrates, which are present in every fertile soil. These may be produced by the decay in the soil of nitrogenous animal or vegetable matters existing in it or supplied to it as manure (see NITRIFICATION); or they may be added to it ready formed.

There are numerous methods for preparing pure or nearly pure nitrogen. One method by which it is obtained very nearly pure is to remove the oxygen as completely as possible from atmospheric air. This can be done by passing a current of air slowly through a red-hot tube packed with copper turnings or with spirals of copper wire gauze. The oxygen of the air combines with the copper to form an oxide of copper, whilst the nitrogen passes on. Or the oxygen can be very completely removed from a confined portion of moist air by suspending in it pieces of phosphorus until the volume of the gas ceases to diminish. Otherwise than from atmospheric air, nitrogen can be prepared by passing a current of chlorine gas into a solution of ammonia. In this method care must be taken always to use ammonia in excess, otherwise chloride of nitrogen would be produced, which is a dangerously explosive substance. A steady current of nitrogen can be very easily obtained by heating together strong solutions of ammonium chloride and of potassium nitrite. The preparation of nitrogen on the large scale, for manufacturing purposes, is now almost exclusively effected by the fractional distillation of liquid air, from which, being more volatile than the accompanying liquid oxygen, it can be obtained in a high degree of purity. Amongst the most important compounds of nitrogen are the nitrates which are found in the soil in very considerable quantity in different parts of the world, and in some places occur in large deposits, as in the nitrate regions of South America. From these nitrates Nitric Acid (q.v.) and other compounds of nitrogen are derived. Several compounds of nitrogen with oxygen are known.

Nitrous Oxide, or laughing-gas, N_2O , was discovered in 1772 by Priestley, who obtained it by the action on nitric oxide of easily oxidisable sub-

stances. It is now prepared by the action of heat on ammonium nitrate:

It is a colourless gas, which can pass with moderate ease be reduced to the liquid state, a pressure of thirty atmospheres being required to liquefy it at 0° C. Davy discovered in 1800 that it possessed anaesthetic properties, and it is now used as an anaesthetic in minor surgical operations. For such purposes it is stored in the liquid state by dentists and others in wrought-iron bottles. It is a supporter of combustion, and burning materials placed in it continue to burn with almost as great brilliancy as if placed in free oxygen.

Nitric Oxide, NO, is produced by the action of nitric acid on copper, silver, or mercury. It is a colourless gas, which like nitrogen can only be reduced to the liquid state by pressure after it has been cooled to a very low temperature. Its most striking character is the great readiness with which it unites with free oxygen, forming dense brown fumes, which consist mainly of nitrogen peroxide (see below).

Nitrous Anhydride has been described as a gas easily condensable to a liquid, possessing the composition represented by the formula N_2O_3 . It seems very questionable whether a single substance exists either in the state of gas or of liquid possessing this composition. The gas which was supposed to be nitrous anhydride was certainly a mixture. Although nitrous anhydride cannot be obtained pure, and the corresponding acid—nitrous acid—is an unstable substance at ordinary temperatures, a number of nitrites, salts corresponding to nitrous acid, are known.

Nitrogen Peroxide, NO_2 or N_2O_4 , is produced when oxygen and nitric oxide are mixed. It is a dark-brown liquid at ordinary temperatures, which boils at 22° C., yielding a brown vapour, and solidifies at -9°, forming colourless crystals. Nitrogen peroxide is produced from atmospheric nitrogen and oxygen in the Birkeland-Eyde electrical process for the manufacture of calcium nitrate, in which the two gases combine at a very high temperature with formation, at first, of nitric oxide. The latter then unites, at a lower temperature, with more oxygen. By the interaction of the resulting nitrogen peroxide with water, dilute nitric acid is formed, and from this, by neutralising it with limestone, calcium nitrate is obtained in solution. The calcium nitrate recovered from the solution by evaporation, and heated with concentrated sulphuric acid, yields nitric acid.

The following are some of the other more important nitrogen compounds: ammonia and the ammonium salts (see AMMONIA); the vegetable alkaloids (see ALKALOIDS); aniline and its derivatives; cyanogen and the cyanides, including hydrocyanic acid; albumenoid substances; urea and uric acid; nitro-benzene, and other nitro compounds; pyridine and allied substances, hydrazine compounds, ptomaines, &c. See AZOTISED BODIES.

Nitrogen Fixation. Two groups of bacteria are known which are capable of utilising the free nitrogen of the air for the purposes of nutrition. A considerable quantity of nitrogen is thus 'fixed' or converted to complex organic compounds in the cells of the organisms. The more important group of the nitrogen-fixing bacteria lives in the nodules on the roots of leguminous and certain other plants and supplies the plants with nitrogen. In return energy-yielding material is received from the plant (see SYMBIOSIS). The organism of the Leguminosæ has been given the name *Bacillus radicicola*. It generally appears as a motile rod, but in the nodules peculiar club-shaped or Y-shaped structures are formed. The bacillus will grow on ordinary

bacteriological media, and also on media containing no combined nitrogen. Several distinct varieties of the organism exist, each of which is associated with a particular genus or with several genera of leguminous plants. The best results, so far as the growth of the plant is concerned, are only obtained when the latter contains in its nodules the type of organism suited to it. It sometimes happens that suitable bacteria for a particular plant are absent from the soil in which it is desired to grow the plant. In those cases beneficial results usually follow the inoculation of the soil with the organism concerned. Most soils in this country contain strains of bacteria generally associated with the majority of leguminous plants. Lucerne, however, is an exception, and inoculation as a rule benefits this crop.

The second group of the nitrogen-fixing bacteria includes forms which live free in the soil. The most important species is an organism generally known as *Azotobacter chroococcum*. This is a large oval or rod-shaped organism which tends to vary greatly in form. It is not present in all soils, the determining factor with regard to its occurrence being the reaction of the soil. *Azotobacter* does not succeed in acid soils; if the acidity of the soil is increased beyond a certain limit the organism will die out. Another of the free-living nitrogen-fixing bacteria is *Bacillus amylobacter*. It is a rod-shaped organism, which is capable of producing spores—bodies which are more resistant to adverse conditions than the ordinary cells of the organism. Most strains of this organism are anaerobic, i.e. they refuse to grow in the presence of free oxygen. *Bacillus amylobacter* is widely distributed, but is not so important as *Azotobacter*, because it fixes much smaller quantities of nitrogen. The nitrogen fixed by free-living bacteria remains in their cells till they die. Then the complex nitrogenous compounds of the bacterial cell are broken down by other bacteria. The nitrogen is converted to nitrates (see NITRIFICATION), in which form it becomes available to the majority of plants.

Nitro-glycerine (known also as *Glonoine* or *Glonoine-oil*) can be readily prepared by dissolving glycerine in equal measures of strong nitric and sulphuric acids and pouring the solution into water, when the nitro-glycerine becomes precipitated. Nitro-glycerine was discovered by Ascanio Sobrero, professor of chemistry at Turin, who in 1846 found that by the above process he could produce a highly explosive mixture. There was little idea at the time of the value of the discovery, which was treated solely as a chemical curiosity, until about fifteen years later, when Alfred Nobel, a Swedish engineer and chemist, perceiving the value of the unrecognised explosive, and turning his attention to its development, rapidly introduced it as a blasting agent for industrial purposes. The new explosive was eminently satisfactory so far as blasting power was concerned; but a considerable number of serious accidents with it, when transported in its liquid state in canisters, led to practically prohibitive legislation in Britain and other countries; and there is little doubt that its manufacture for practical use would have ceased had not Nobel in 1864 discovered that kieselguhr (an infusorial earth) would absorb it and form a plastic mass containing, as a maximum, about three parts by weight of nitro-glycerine to one of kieselguhr. This mixture can be safely handled, and is formed, by suitable means, into cylindrical cartridges which are wrapped in parchment paper. Confidence in the new explosive being gradually restored, its properties were carefully studied by Nobel and others, with the result that it now forms part not only of the majority of blasting explosives but of many propellants, notably of *Cordite* (q.v.), the

smokeless explosive used for cannon and small-arms by Great Britain. Nitro-glycerine was first manufactured in the British Isles in 1871 at Ardeer, in north Ayrshire, by the British Dynamite Company, which in 1876 became, and still is, Nobel's Explosives Company. This factory held a practical monopoly of the manufacture of nitro-glycerine for the British Isles from 1871 to 1881.

Nitro-glycerine, as manufactured on a large scale for commercial purposes, is formed by the mixture of strong nitric and sulphuric acids, cooled by water previous to being introduced into a large leaden vessel, the temperature of which is kept down by water circulating through coils inside. Glycerine is then injected by compressed air as a fine spray from the bottom of the vessel, and becomes immediately nitrated, considerable heat being evolved. On the completion of the nitration, as indicated by the fall of temperature, the mixture is cooled down to about 60° F. (15° C.) and then run off into another leaden vessel, termed the 'separating tank,' where it is allowed to stand. In about an hour the separation of the nitro-glycerine from the acids is complete, and the former, having a specific gravity of 1.6, as compared with about 1.74 for the mixture of acids, floats and forms a layer on the top of the latter. From this position it is run off into washing tanks and thoroughly washed in water, and subsequently in an alkaline solution, to remove every trace of acid; and, having been passed through a filter of common salt contained in a bag of flannel, is ready for manufacture into Dynamite (q.v.) or other nitro-glycerine compounds. A variant of the process described is one in which the nitration and separation take place in the same vessel. The utmost care is exercised in the above processes, and any abnormal rise in temperature is strictly guarded against, or accidents would arise. For similar reasons the materials employed in the manufacture of nitro-glycerine are in every particular the best and purest attainable. Colourless when pure, but having as an article of commerce a pale yellow colour, nitro-glycerine is a dense, oily liquid. It is inodorous, but has a sweet, pungent, aromatic taste; a single drop, however, if placed on the back of the tongue, the inhaling of the vapour, or even in some cases the mere handling, of the explosive will produce headache and pain in the back lasting for hours; but by those accustomed to handling this substance no inconvenience whatever is experienced. Nitro-glycerine enters into medical prescriptions for certain diseases of the heart.

The formation of nitro-glycerine, $C_3H_5(ONO_2)_3$, from glycerine, $C_3H_5(OH)_3$, by the action of nitric acid, HNO_3 , is expressed by the formula,

The sulphuric acid used in the process described above, in the proportion of about 1.7 part to 1 part of nitric acid, plays no part in the reaction, but is essential in order to maintain the strength of the nitric acid by combining with the water formed in the reaction as shown in the equation given above. If a small quantity of nitro-glycerine be ignited in the open air it will usually burn quietly, but if confined in any way burning will lead to detonation. It is readily detonated by a blow or by a detonator (for an explanation of detonation see GUN-COTTON); but when frozen the blow needed to detonate it is considerably increased, and as it freezes at a comparatively high temperature—which varies for different samples, but is approximately 50° F. (10° C.)—and contracts by about one-twelfth of its volume on freezing, these characteristics are distinctly objectionable when it is used absorbed by kieselguhr or other substances,

or dissolved with nitro-cellulose, as in ballistite or cordite, though in solution the freezing-point is considerably lowered. A further but lesser objection to it is that it vaporises slightly at ordinary temperatures, and decomposes readily at about 270° F. (132° C.). On detonation the products are carbonic acid gas (CO_2), water (H_2O), nitrogen (N), and oxygen (O), according to the following equation,

from which it will be seen that there is oxygen available for further combustion if a combustible be mixed with it, and this property is made use of in certain explosives. One volume of nitro-glycerine produces 1141 volumes of gas (the water formed being reckoned as gaseous) when detonated; and this enormous expansion, rendered still greater by the immense heat, estimated at 6152° F. (3400° C.), generated on detonation enables this explosive to exert a pressure some three times as great as that obtained from gunpowder when the latter is exploded in its own volume, a condition which cannot obtain practically. As the maximum velocity of detonation of nitro-glycerine is about 28,000 f.s. as compared with about 800 f.s. for gunpowder, no comparison is possible between the effects of these explosives when untamped. See DYNAMITE, GUN-COTTON.

For fuller details see Berthelot, *Explosives and their Power* (1892); Guttman, *The Manufacture of Explosives* (1895); *Treatise on Service Explosives* (Official, 1907); and similar works.

Nitrous Ether, or NITRITE OF ETHYL, $C_2H_5NO_2$, is a very volatile ether, with an agreeable apple odour, and having a specific gravity of .900. It boils at 64.4° (18° C.), and is highly inflammable. It is readily soluble in alcohol and glycerine, less so in water. It is very liable to decomposition, becoming acid on keeping. It may be prepared by the action of sulphuric acid and alcohol on nitrite of potash. In itself it is of little importance, but on account of its relation to the *sweet spirits of nitre* or *spirit of nitrous ether* is one of the most important drugs. It was for long thought that the virtues of this valuable remedy were proportionally due to the nitrous ether present, and attention was directed to the preparation of the pure substance. When this was administered in the form of solution of the strength of sweet spirits of nitre, it was found that its action was different from and inferior to that of the latter. The sweet spirits of nitre contains in addition aldehyde and paraldehyde, and it is believed that to these we must ascribe much of its virtue. Be this as it may, the legal test is based on the presence of some ethereal body, presumably nitrite of ethyl, and yet many a sample may be efficacious and fail to satisfy the standard test. The *spirit* should be freshly made, be kept in well-closed bottles, and should not be acid. Its specific gravity should not exceed .845, as an admixture of water tends towards decomposition. It may be prepared by the action of nitric and sulphuric acids on alcohol in the presence of copper, but manufacturers attain the same end by other processes. It is used, in conjunction with other medicines, as a diuretic, especially in the dropsy which follows scarlatina; and it is employed, in combination with acetate of ammonia and tartarised antimony, in febrile affections. The dose in febrile cases is from half a drachm to a couple of drachms; while for a diuretic two or three drachms should be given.

Nitrous Oxide. See NITROGEN.

Nivelles (Flem. *Nyvel*), a town in the Belgian province of Brabant, on the Thines, 19 miles by rail

S. of Brussels. Its fine Romanesque church (1045) contains the relics of Pepin's daughter, St Gertrude. In 1381 the townsfolk of Ghent were defeated here by Count Louis of Flanders, and 6000 burned in a monastery. Nivelles has manufactures of cotton, paper, lace, &c. Pop. 12,000.

Nivernais, formerly a province in the middle of France, nearly corresponding to the present department of Nièvre. Its towns enjoyed municipal privileges at a very early period. The principal landowners were the counts, afterwards dukes, of Nevers, who held under their vassalage more than 1800 fiefs.

Nix, NIXIE, a class, mostly malignant, of northern water-spirits. See DEMONOLOGY.

Nizam's Dominions. See HYDERABAD.

Noah. See DELUGE.

Noailles, a distinguished French family which dates from the 11th century, and played an important part in history from the reign of Louis XIV. to the Revolution. Antoine (1504-62) was ambassador in England in 1553-56, and admiral of France. Anne Jules (1650-1708), son of the first duke, commanded against the Huguenots and in Spain during the war of the Spanish succession, and was made marshal; whilst his brother, Louis Antoine (1651-1729), was Archbishop of Paris from 1695 till his death, and was made cardinal in 1700. The third duke, Adrien Maurice (1678-1766), won the marshal's baton in the wars of Louis XV. in Spain, Italy, and Germany. The fifth duke, Paul François (1739-1824), attained eminence as a chemist and was elected to the Academy of Sciences in 1777; his brother, Emmanuel Marie Louis (1743-1822), was French ambassador at Amsterdam (1770-76), London (1776-83), and Vienna (1783-92). The sixth duke, Paul (1802-85), wrote historical works, and was elected to Chateaubriand's chair in the Academy in 1849. A grandson of the third duke, Louis Marie (1756-1804), served in America under his brother-in-law Lafayette, embraced for a while the French Revolution, and defended San Domingo against the British.

Noailles, PRINCESSE ANNA ELISABETH BRANCOVAN, COMTESSE DE, born in Paris in 1876, of noble and princely Wallachian-Moldavian-Greek origin (a granddaughter of Musurus Pasha, Turkish ambassador in London), lived for a time in the East, married Comte Mathieu de Noailles, and was hailed by some critics as the world's greatest poet of her time. *Le Cœur Innombrable* (1901), *L'Ombre des Jours*, *Les Éblouissements*, *Les Vivants et les Morts* (1913), *Les Forces Éternelles*, comprise her voluptuous melancholy poetry. Her novels have enjoyed a lesser repute.

Nobel, ALFRED (1833-96), was born at Stockholm and educated at St Petersburg, where he afterwards joined his father in the manufacture of explosives and torpedoes. He studied mechanical engineering in the United States, and in 1867 invented dynamite, and subsequently the first smokeless powder. He held 129 patents in Britain, and controlled fifteen explosive factories in different parts of the world. He left £1,680,000 for the founding of five prizes to be awarded annually to the five most deserving persons in (1) physics, (2) chemistry, (3) physiology or medicine, (4) literary work of an idealistic nature, (5) the cause of universal peace. The first four are awarded by the Academies of Sweden, the fifth by the Norwegian Storting. These prizes are open to all nations without restriction of sex. The awards were first made in December 1901, and have been continued annually.

Nobility, that distinction of rank in civil society which raises a man above the condition of

the mass of the people. Privileges originally acquired by wealth or political power are secured to the family of the possessor of them; and the privileged class come to constitute an order, admission into which requires the consent of society or of the order itself.

The ancient Romans were divided into *nobiles* and *ignobiles*, a distinction at first corresponding to that of patricians and plebeians. A new nobility afterwards sprang out of the plebeian order, and obtained (336 B.C.) the right to rise to high offices in the state; and in course of time the descendants of those who had filled curule magistracies inherited the *jus imaginum*, or right of having images of their ancestors—a privilege which, like the coat-of-arms in later ages, was considered the criterion of nobility. The man entitled to have his own image was a *novus homo*, while the *ignobilis* could neither have his ancestor's image nor his own.

The origin of the feudal aristocracy of Europe is in part connected with the accidents which influenced the division of conquered lands among the leaders and warriors of the nations that overthrew the Roman empire, and is sketched in the article Feudalism (q.v.); and the evolution of the dignities of Baron, Count (*Comes*), Earl, Marquis, Duke, and other ranks will be found under those several heads. In the subinfeudations of the greater nobility originated a secondary sort of nobility, under the name of Vavasours, Castellans, and lesser barons; and a third order below them comprised vassals, whose tenure, by the military obligation known in England as knight's service, admitted them within the ranks of the aristocracy. In France the allegiance of the lesser nobles to their intermediary lord long continued a reality; in England, on the other hand, William the Conqueror obliged not only his barons who held in chief of the crown, but their vassals also, to take an oath of fealty to himself; and his successors altogether abolished subinfeudation. The military tenant, who held but a portion of a knight's fee, participated in all the privileges of nobility, and an impassable barrier existed between his order and the common people. Over continental Europe in general the nobles, greater and lesser, were in use, after the 10th century, to assume a territorial name from their castles or the principal town or village on their demesne; hence the prefix 'de,' or its German equivalent 'von,' considered over a great part of the Continent as the criterion of nobility or gentility. Britain was, to a great extent, an exception to this rule, many of the most distinguished family names of the aristocracy not having a territorial origin. See NAMES.

Under the feeble successors of Charlemagne the dukes, marquises, and counts of the empire encroached more and more on the royal authority, and by the end of the 9th century the Carolingian empire had been parcelled into separate and independent principalities, under the dominion of powerful nobles, against whom, in Germany, the crown never recovered its power. In France, however, the royal authority gradually revived under the Capetian race, the great fiefs of the higher nobility being one by one absorbed by the crown. In England, where the subjection of the feudal aristocracy to the crown always was, and continued to be a reality, the resistance of the nobles to the royal encroachments was the means of rearing the great fabric of constitutional liberty. All those who, after the Conquest, held *in capite* from William belonged to the nobility. Such of them as held by barony (the highest form of tenure) are enumerated in Domesday. Their dignity was territorial, not personal, having no existence apart from baronial possession. The *comes* was a baron of superior dignity and greater estates; and these

were in England the only names of dignity till the time of Henry III.

After the introduction of Heraldry (q.v.), and its reduction to a system, the possession of a coat-of-arms was a recognised distinction between the noble and the plebeian. On the Continent whoever had a shield of arms was a nobleman; and in every country of continental Europe a grant of arms, or letters of nobility, was conferred on all such a noble's descendants. In England, on the other hand, the words noble and nobility are restricted to the five ranks of the peerage constituting the greater nobility, and to the head of the family, to whom alone the title belongs. Gentility, in its more strict sense, corresponds to the nobility of continental countries (see GENTLEMAN). This difference of usage is a frequent source of misapprehension on both sides of the Channel; at some of the minor German courts the untitled member of an English family of ancient and distinguished blood and lineage was sometimes postponed to a recently-created baron or 'Herr von,' who had received that title, and the gentility accompanying it, along with his commission in the army. It was taken for granted that the latter belonged to the 'Adel' or nobility, and not the former. For the German nobility (abolished at the revolution), see GERMANY. Throughout the middle ages the lesser nobility of Britain preserved a position above that of most continental countries, being, unlike the corresponding class in Germany, allowed to intermarry with the high nobility, and even with the blood-royal of their country.

The higher nobility, or nobility in the exclusive sense, of England consist of the five temporal ranks of the peerage—Duke, Marquis, Earl, Viscount, and Baron (in the restricted signification of the word, q.v.), who are members of the Upper House of Parliament. Archbishops and bishops are lords temporal, but not peers. The dignity of the peerage is hereditary, but in early times was territorial, the dignity originally being attached to the possession of lands held directly from the crown in return for services to be performed to the sovereign. Later, peers were created by writ of summons to attend the king's council or parliament, but now the creation of a new peer is always made by letters-patent from the crown. In order to the efficient carrying out of the appellate jurisdiction of the House of Lords there are now a limited number of life peers, styled Lords of Appeal in Ordinary. By the Appellate Jurisdiction Act, 1876, as amended 1887, it is enacted that every such lord, unless he is otherwise entitled to sit in the House of Lords, shall by virtue and according to the date of his appointment be entitled during his life to rank as a baron, and shall be entitled to a writ of summons to attend and to sit and vote in the House of Lords. But his dignity is not to descend to his heirs. A peerage is forfeited by attainder for high-treason; attainder for felony forfeits a peerage by writ, not by patent; on attainder, peerage cannot be restored by the crown, only by an act of parliament. Ladies may be peeresses in their own right either by creation or by inheritance. The wives of peers are also styled peeresses. The question as to descent through males only or heirs-female will be found noted at the articles on the several orders of nobility. The oldest English peerage is the earldom of Arundel, dating from 1155, and now held by the Dukes of Norfolk; the Irish barony of Kingsale dates from 1181; to the period 1181–1205 belong four baronies now merged in other titles; the Scottish earldom of Sutherland goes back to 1228; and the baronies of Le Despencer, De Ros, and Hastings are all of the year 1264.

By the Act of Union between England and

Scotland the Scottish peers elect sixteen of their number to represent their body in the House of Lords in each parliament. The peers of Ireland, in virtue of the Irish Act of Union, elect twenty-eight of their number to sit in the House of Lords for life. The Act of Union with Scotland has been understood to debar the sovereign from creating any new Scottish peerages; all peers created in either England or Scotland between that date and the union with Ireland are peers of Great Britain; and peers created in any of the three kingdoms subsequently to the union with Ireland are peers of the United Kingdom, with this exception that one new peerage of Ireland may be created on the extinction of three existing peerages. When the Irish peers are reduced to one hundred, then on the extinction of one peerage another may be created. All peers of Great Britain or of the United Kingdom have a seat in the House of Lords. A Scottish peer, though not one of the sixteen representative peers, is debarred from sitting in the House of Commons, a disability which does not attach to Irish peers. The privileges belonging to peers as members of parliament will be explained under PARLIAMENT; as peers, they also possess the following immunities: they can only be tried by their peers for felony, treason, or misprision of treason, when the whole members of the peerage are summoned. All the privileges belonging to the English peers, except the right of sitting in the House of Lords, were extended to the peers of Scotland by the Treaty of Union. A peer who has different titles in the peerage takes in ordinary parlance his highest title, one of the inferior titles being given by courtesy to his eldest son. Certain Courtesy Titles (q.v.) belong also to the daughters and younger sons of a peer, but do not extend to their children. British subjects can hold foreign titles of nobility only by consent of the crown. The Scottish barony of Fairfax (1627) was from 1800 confirmed to American citizens, landholders in Virginia. The sixth baron was a friend of Washington, the tenth (1829–69) speaker of the California House of Representatives, the twelfth a Scottish representative peer (1917). The Canadian barons of Longueuil obtained recognition in Britain in 1880 (see LE MOYNE).

In France a limited body of the higher nobility, styled the peers, were in the enjoyment of privileges not possessed by the rest. The title of Duke was subject to strict rule, but many titles of Marquis and Count, believed to be pure assumptions, were recognised by the courtesy of society. The head of a noble family often assumed at his own hand the title of marquis; and if an estate was purchased which had belonged to a titled family the purchaser was in the habit of transferring to himself the honours possessed by his predecessor—a practice to which Louis XV. put a stop. Immediately before the Revolution 80,000 families claimed nobility, many of them of obscure station, and less than 3000 of ancient lineage. Nobles and clergy together possessed two-thirds of the land. Practically, the estimation in which a member of the French nobility was held depended not so much on the degree of his title as on its antiquity, and the distinction of those who had borne it. The higher titles of nobility were not borne by all members of a family; each son assumed a title from one of the family estates—a custom productive of no small confusion. Unlike 'roturier' lands, which divided among all the children equally, noble fiefs went to the eldest son. The Revolution overthrew all distinction of ranks. On 18th June 1790 the National Assembly decreed that hereditary nobility was an institution incompatible with a free state, and that titles, arms, and liveries should be abolished. Two years later the records of the nobility were burned. A new

nobility was created by the Emperor Napoleon I. in 1808, with titles descending to the eldest son. The old nobility was again revived at the Restoration. All marquises and viscounts are of pre-revolution titles, none having been created in later times.

Commercial pursuits have more or less in different countries been considered incompatible with nobility. In England this was less the case than in France and Germany, where for long a gentleman could not engage in any trade without losing his rank. A sort of commercial 'Bürger-Adel,' or half-gentleman class, was constituted out of the patrician families of some of the great German cities, particularly Augsburg, Nürnberg, and Frankfurt, on whom the emperors bestowed coats-of-arms. In semi-feudal Italy there was on the whole less antagonism between nobility and trade than north of the Alps. The aristocracy of Venice had its origin in commerce; and, though untitled, they were among the most distinguished class of nobles in Europe. On the other hand, in Florence, in the 14th century, under a constitution purely mercantile, nobility became a disqualification from holding any office of the state. In order to the enjoyment of civil right, the nobleman had to be struck off the rolls of nobility; and an unpopular plebeian was sometimes ennobled in order to disfranchise him. A little later there grew up, side by side with the old nobility, a race of plebeian nobles—as the Medici—whose pretensions were originally derived from wealth, and who eventually came to be regarded as aristocrats by the democratic party.

The nobility of Spain boasts of a special antiquity and purity of blood, a descent from warriors and conquerors alone. 'Hidalgo' (q.v.) is a term which implies gentility or nobility; the hidalgo alone has in strictness a right to the title 'Don,' which has latterly been used by persons who have no proper claim to it about as extensively as 'Esquire' in England. The higher nobility are styled *Grandees* (q.v.); the class of nobility below them are called 'Titulados.' Red blood is said to flow in the veins of the hidalgo, blue in that of the grandee. The preservation of noble blood, untainted by plebeian intermixture, has often been reckoned a matter of much moment. In Spain most of all this purity of lineage has been jealously guarded. In the German empire no succession was allowed to feus holding immediately of the emperor, unless both parents belonged to the higher nobility. In France the offspring of a gentleman by a plebeian mother was noble in a question of inheritance or exemption from tribute, but could not be received into any order of chivalry. Letters of nobility were sometimes granted to reinstate persons in this position. In Norway titular hereditary nobility was abolished in 1821; in Sweden it still survives. It was in Germany important for many purposes to possess eight or sixteen quarterings—i.e. to be able to show purity of blood for four or five generations, the father and mother, the two grandmothers, the four great-grandmothers, and also, in case of the sixteen quarterings, the eight great-great-grandmothers, having all been entitled to coat-armour. Among the higher grades of the peerage in England many do not possess this complete nobility. By the German constitution of 1919 titles of nobility count only as parts of a name. Austria and Czechoslovakia abolished nobility in 1919 and 1918.

See especially *The Complete Peerage*, by G. E. Cokayne (new ed., revised and enlarged by the Hon. Vicary Gibbs, 12 vols. 1910 *et seq.*); the works of May, Hallam, Stubbs, Herbert Spencer, and Round; Sir H. Nicolas's *Historical Peerage* (1825; new ed. by Courthope, 1856); Freeman's *Comparative Politics* (1873); also the *Peerages of Debrett* (since 1802), *Burke* (since 1826), and *J. Foster* (since

1880); and Balfour Paul, *Scots Peerage* (1904 *et seq.*, founding on Douglas 1764 and Wood 1813).

Noble, a gold coin first minted by Edward III., and so called from its being of noble metal: on the one side was a ship, in allusion to Edward's victory at Sluys. The original value was half a mark, or 6s. 8d. A later issue (Edward IV.) bore a rose on the same side as the ship. These were called *rose-nobles* and *ryals*. Silver having depreciated, the value of the noble rose to 10s. (much greater purchasing value than now), and a new coin of the old value was issued, called the *Angel* (q.v.).

Nocera Inferiore, an episcopal city of South Italy, 8 miles NW. of Salerno; pop. (commune) 24,000. *Nocera Superiore*, a village near by, has 8000 inhabitants.

Noctiluca (lit., 'night-light'), a very abundant, luminescent, marine Infusorian, in the group of Cystoflagellates. In shape like a miniature melon, $\frac{1}{8}$ in. or more in diameter, it has a strong locomotor flagellum as long as the rest of the animal, and a small food-wafting flagellum in the mouth-groove. There is a firm cuticle, and the living matter is much vacuolated. One may become two (fission) or two may become one (conjugation), the latter process being followed by spore-formation. The luminosity is excited by any form of irritation, and is the commonest marine 'phosphorescence.' See INFUSORIA, PHOSPHORESCENCE.

Nocturn. See BREVIARY.

Nocturne ('night-piece'), a dreamy musical piece, generally for the piano, especially associated with the names of Field (q.v.), its inventor, and Chopin. See MUSIC.

Nodal Lines. See HARMONICS, SOUND.

Noddy (*Anous*), a genus of birds of the family Laridae, differing from terns in having the bill slightly angular, thus exhibiting an approach to

Noddy (*Anous stolidus*).

gulls, and the tail not forked, but somewhat wedge-shaped. Altogether seven species are enumerated, widely distributed throughout the tropics and in the temperate zones. One species (*A. stolidus*) has been recorded as found off Wexford and in Dublin Bay, but no specimens other than the two obtained there have been taken in the British Isles or on the Continent. It is a familiar bird in the Atlantic and Pacific Oceans, not unfrequently alighting on vessels and suffering itself to be taken by the hand; and so at its breeding-places also, where, not accustomed to the visits of man, it scarcely gets out of the way, and the female sits undisturbed on the nest. Hence it commonly shares with the booby the reputation of unusual stupidity. It is about 15 or 16 inches long, from the tip of the bill to the end of the tail, the general colour being a brownish black. The food consists chiefly

of small fish and molluscs. Particular islands seem to be specially selected as the breeding-places of noddies, among them being the Bahamas, many of the Keys of the West Indies, the Laccadives, St Helena, Ascension, and many islands of Polynesia and Australia. Their nests, which are built on shelves of rocks or patches of sand or on trees, are sometimes very closely placed together. Each nest generally contains only one egg, which is about two inches long and of a buff colour, sparsely speckled with reddish brown. The eggs are very good to eat, and in some places are collected in large numbers. The other species of noddy are distinguished by their smaller size and slightly different colour.

Nodes, in Astronomy, are the two points in which the orbit of a planet intersects the plane of the ecliptic, the one through which the planet passes from the south to the north side of the ecliptic being called the *ascending node* (Ω), and the other the *descending node* (ϖ). As all the bodies of the solar system, whether planets or comets, move in orbits variously inclined to the ecliptic, the orbit of each possesses two nodes, and a straight line drawn joining these two points is called the *line of nodes* of each body. It is scarcely necessary to add that as the earth moves in the plane of the ecliptic she has no nodes. The places of the nodes are not fixed points on the plane of the ecliptic, but are in a constant state of fluctuation, sometimes *advancing* (eastward), and at other times *receding* (moving westward). This motion is produced by the mutual attractions of the planets, which tend to draw each of them out of the plane of its orbit; and it depends upon the relative positions of the planets with respect to another planet whether that planet's nodes shall advance or recede. On the whole, however, the majority of possible 'relative positions,' or *configurations*, as they are called, is in favour of a retrograde motion; and we find by observation that in an average of many revolutions round the sun a constant retrogradation of the node takes place. The determination of this retrogradation in the case of the planets is a most complicated problem, as the separate action of each on the others has to be taken into account. The revolutions of the planetary nodes are accomplished very slowly, never amounting to as much as a single degree in a century. The nodes of the lunar orbit retrograde with much greater speed under the disturbing influence of the sun. It is owing to the fact that they complete a revolution in nearly eighteen Julian years and eleven days that series of eclipses regularly recur in that period. See ECLIPSES, ORBIT, PERTURBATIONS; and Herschel's *Outlines of Astronomy*.

Nodes, in Botany. See STEM.

Nodier, CHARLES, a considerable French writer, was born at Besançon, 29th April 1780 (Sainte-Beuve), in 1781 (Weiss), or even 1783 (Quérard), the son of a revolutionist lawyer. He lived a shiftless life at Paris, Besançon, Dôle, Laibach, and last again at Paris, where he was appointed in 1823 to the librarianship of the Bibliothèque de l' Arsenal. As a child an ardent Jacobin, he became a royalist at the Restoration, was elected to the Academy in 1833, and died 27th January 1844. He was a devoted student of entomology, philology, and bibliography, but his importance in literature depends mainly upon the influence his personality exerted on the group of Romanticists of 1830. Of his delightfully fresh and fantastic short stories may here be named *Smarrar*, *Histoire du Roi de Bohême et de ses sept Châteaux*, *La Fée aux Miettes*, *Inès de las Sierras*, *La Légende de Sœur Béatrix*, *Franciscus Columna*, and his volume of Fairy-tales.

His *Souvenirs de Jeunesse* (1832) must not be taken too seriously; the *Œuvres Complètes* (12 vols. 1832-34) are far from complete. There are Lives by Wey (1844) and Mme. Ménessier-Nodier (1867). See also Mérimée's *éloge*, Sainte Beuve's *Portraits Littéraires*, and *Main Currents of 19th Century Literature*, by Brandes.

Noé. See CHAM.

Noetians. See PATRIPASSIANS.

Nogent-le-Rotrou, a town in the French department of Eure-et-Loir, 93 miles SW. of Paris, with the ruined château of the great Sully. The Germans here won two fights in 1870-71. Pop. 7400.

Nogi, COUNT MARASUKE, a Samurai, born in 1849, served in the Satsuma Rebellion, held high command in the war with China in 1894, and in the Russian war, 1904-5, commanded the third army, took Port Arthur, and at the battle of Mukden turned the Russian right. His two sons fell in the war. On the funeral of the Emperor Mutsuhito (14th September 1912) Count Nogi and his wife solemnly committed suicide. See books by Kinya Tamaru (1913) and Stanley Washburn (1913).

Noisseville, a village of Lorraine, 5 miles E. of Metz, where, on 31st August—1st September 1870, Bazaine unsuccessfully attacked the German besiegers of Metz.

Nola, an episcopal city of Italy, 16 miles ENE. of Naples. It is built on the site of one of the oldest cities of Campania, founded by the Ausonians, and taken by the Romans in the Samnite war, 313 B.C. Augustus died here, 14 A.D. Pop. 16,000.

Noli me tangere. See LUPUS, TUBERCLE.

Nollekens, JOSEPH, was born in London, 11th August 1737, the son of a painter from Antwerp. Being placed in the studio of Scheemakers the sculptor, he made such progress that the Society of Arts repeatedly awarded him valuable prizes. In 1760 he settled in Rome. Garrick, whom he met there in the Vatican, immediately recognised his countryman as the young sculptor to whom the prizes had been awarded by the Society of Arts, sat to him for his bust, and paid him handsomely for it. He also executed in Rome a bust of Sterne in terra cotta, which added greatly to his reputation. After residing ten years in Rome he returned to London, where he set up his studio; and the reputation he had acquired in Rome was such that he immediately had full employment, and within a year after (in 1771) was elected an Associate of the Academy, and a Royal Academician the following year. His forte was in modelling busts; and through them he has handed down the likenesses of most of the important personages who figured in Great Britain in the end of the 18th and at the commencement of the 19th century—of Samuel Johnson, who was his friend and frequent visitor, of Fox, Pitt, and other political characters. George III. also sat to him. Besides busts, Nollekens executed numerous commissions for public monuments and statues. He also executed a number of classical and mythological statues and groups. He died in London, 23d April 1823, leaving no children to inherit a fortune of £200,000. See Life by J. T. Smith (1828; new ed. 1920).

Nolle Prosequi, a term used in English law to denote that the plaintiff does not intend to go further with the action.

No Man's Land, originally a name applied to outlying districts in various regions, especially at one time to what now corresponds mainly to Griqualand East (q.v.), and also to a territory of 80,000 sq. m. in South Australia. More recently the term has come to mean the strip of land lying between the entrenchments of opposing armies during war.

Nom de Plume, somewhat doubtful French for *nom de guerre* or Pseudonym (q.v.).

Nominalism, a famous controverted doctrine of the middle ages, respecting the nature of our general or abstract ideas, or of 'universals.' It was contended by some that abstractions—as a circle in the abstract, beauty, right—had a real existence apart from round things, beautiful objects, right actions. This was called Realism. Those who held the opposite view were called Nominalists, because they maintained that there is nothing general but *names*; the name 'circle' is applied to everything that is round, and is a general name; but no independent fact or property exists corresponding to the name. Specifically the controversy was as to the existence of 'universals' or of genera and species, and arose out of a passage in the Latin translation of Porphyry's *Isagoge*. The watchwords of three schools were *universalia ante res*, 'the universals before the concrete things,' of Platonic Realism; *universalia in re*, 'the universals in the thing,' held to be Aristotelian Realism; *universalia post rem*, 'the universals after the thing,' covering both Nominalism (that the universals were but *flatus vocis*, sounds) and Conceptualism (that the universals had an existence in the mind of the thinker).

Scholastic Realism of what was regarded as the Aristotelian type prevailed until the 11th century, when Roscelin defended a distinctly Nominalistic doctrine. Unhappily he applied his philosophy to the doctrine of the Trinity, and arrived at a tritheistic heresy, which (and Nominalism with it) was condemned by the church. Henceforward Nominalism carried with it, not unreasonably altogether, a savour of heresy and rationalism, and Realism was dominant, though the controversy raged throughout the 12th century. Abelard was a modified Realist; Albertus Magnus, Aquinas, and Duns Scotus were Realists of a kind, though in the 13th and 14th centuries the feud between Nominalists and Realists was no longer the central debate of scholasticism. Nominalism triumphed with William of Ockham (died 1347), with whom scholasticism may be held to have begun to dissolve. See SCHOLASTICISM, and works quoted there; the articles on the chief mediæval thinkers; the article PHILOSOPHY; and monographs by Exner (1841), Köhler (1858), and Löwe (1876).

Non-combatants. See COMBATANTS.

Non-commissioned Officers, in the British army (*sous-officiers* in the French, and *unter-offiziere* in the German), form a most valuable and important class, intermediate between the commissioned officers and the men. It is essential that some persons in authority should live amongst the men, superintend their Mess (q.v.), teach them their drill and duties, take charge of small parties on duty and in the field, and, generally, overlook them in every way. None are so well fitted to do so as those who are selected from amongst the men themselves, after several years' service as private soldiers, for promotion to non-commissioned rank. They must be well qualified by good conduct, tact, temper, education, and knowledge of military duties—in the two last mentioned they must pass examinations—and the efficiency of the corps will largely depend upon the way in which they do their duty. Besides extra pay, they enjoy special privileges, and many obtain commissions as officers. All quartermasters and riding-masters are selected from amongst them, and it is becoming more and more common to promote picked men to commissioned rank in all branches of the service. They can only be reduced to the ranks, or to a lower grade, by sentence of a court-martial, and cannot be subjected to any minor

punishment except a reprimand. The following are included in the term 'non-commissioned officer': master-gunners, 3d class (who have charge of the armament and magazines in a fort), staff-clerks, all Sergeants (q.v.), Corporals (q.v.), and Bombardiers (q.v.). Sergeants have a separate Mess (q.v.), and in most barracks there is a corporals' room. The proportion of non-commissioned officers to other soldiers in a battalion at war strength is 91 to 959; in a regiment of cavalry, 83 to 551; and in a battery of artillery, 21 to 149. Warrant officers rank above non-commissioned officers, from whom they are nearly all selected. For the Navy, see PETTY OFFICERS, WARRANT OFFICERS.

Nonconformists, a name sometimes given generally to all sectaries who, at any period in English history since the establishment of Protestantism, have refused to conform to the doctrine and practices of the Episcopal Church. It is used in a restricted sense to denote the clergy who in 1662—two years after the Restoration—left the Church of England rather than submit to the conditions of the Act of Uniformity. In 1727 the Presbyterians, Independents, and Baptists received some special legal recognition, and came to be known as the Three Denominations. See ENGLAND (CHURCH OF), PRESBYTERIANS, INDEPENDENTS, &c.

Non-effective (Fr. *non-activité*) is the term used to describe the status of officers of the British army or navy who are on retired or half-pay. Non-commissioned officers and men who are discharged, die, or desert are also said to become 'non-effective.'

Nones. See CALENDARS.

Nonius Marcellus, a Latin grammarian, of whose life nothing is known. Probably a Numidian, born in Thubursicum, as his surname *Tuburticensis* suggests, he seems to have lived about the end of the 3d or the beginning of the 4th century. His name is attached to a treatise in eighteen chapters, without arrangement or critical sagacity, but precious as preserving many words in forgotten senses, and passages from books of ancient Latin authors now lost. See edition by J. H. Onions.

Nonjurors, the name given to that portion of the clergy in both England and Scotland who, having taken the oath of allegiance to James II., refused at the Revolution to take it to William and Mary. An act of parliament required them all to take this oath by 1st August 1689, six months' grace being allowed before deprivation; but it was refused by Archbishop Sancroft of Canterbury, by Bishops Ken of Bath and Wells, Turner of Ely, Frampton of Gloucester, Lloyd of Norwich, White of Peterborough, Thomas of Worcester, Lake of Chichester, and Cartwright of Chester (the three last died during the year), and by about 400 of the English clergy. In Scotland, where all the bishops refused the oath, Episcopacy was abolished in 1689, and more than 300 clergymen were thrust out; and not till the death of Prince Charles Edward in 1788 did the Protestant bishops in Scotland, 'upon mature deliberation with their clergy, unanimously agree to comply with and submit to the government of King George III.,' nor until four years later did the bill for their relief receive the royal assent. South of the Tweed the schism was perpetuated by the consecration in 1694 of Hickeys (q.v.) and Wagstaffe as suffragan bishops of Thetford and Ipswich, in 1713 of Jeremy Collier (q.v.) and two others, as also by the introduction in 1718 of the 'usages' (a new communion office, prayer for the dead, mixed chalice, &c.). Thereby, however, for some thirteen years the Nonjurors themselves were split into two bodies, both ordaining bishops, till the

dispute was terminated by the general adoption of the 'usages.' A fresh breach occurred through the consecration in 1733 of Roger Lawrence by a single Scotch bishop; and this branch supplied some adherents to the rebellion of the '45, in which none of the regular body were involved. For, High Churchmen as were all the Nonjurors, and believers in the doctrine of passive obedience, it is a great mistake to imagine that they were all Jacobites, or, at anyrate, active Jacobites; while, on the other hand, there were many active Jacobites who were not Nonjurors (for instance, Atterbury). Robert Gordon, the last of the regular Nonjuring bishops, died in 1779; Booth, the last of the irregular Nonjuring bishops, in 1805; and James Yeowell, probably the very last Nonjuror, long the sub-editor of *Notes and Queries*, in 1875. Nonjurors, not mentioned already, were Thomas Baker, Carte, Hearne, William Law (q.v.), Charles Leslie, and Robert Nelson (q.v.).

See JACOBITES, and works there cited; Lathbury's *History of the Nonjurors* (1845); Canon Overton's *The Non-jurors* (1902); H. Broxap's *The Later Non-jurors* (1924).

Non Nobis Domine. See GRACE.

Non Possumus (Lat., 'we cannot'), a papal formula taken from Acts, iv. 20 (Vulgate), and said to have been used by Pope Clement VII. in reply to Henry VIII.'s demand for the dissolution of his marriage with Catharine of Aragon; used in general expression for the refusal of the Roman curia to yield to the demands of the temporal power.

Non-residence. See PLURALISM.

Non-suit is a legal term in England, which means that, where a plaintiff in a jury trial finds he will lose his case owing to some defect or accident, he is allowed to be non-suited, instead of allowing a verdict and judgment to go for the defendant. But there is now, in general, no difference between the effect of a non-suit and that of a verdict for the defendant.

Non-user. See DESUETUDE.

Nootka Sound, a harbour on the west coast of Vancouver Island, British Columbia. Its entrance is protected by Nootka Island.

Norbertines. See PREMONSTRATENSIS.

Nord, the most northerly department in France (whence its name), corresponding with the former province of French Flanders, and bordering on Belgium and the Strait of Dover. Area, 2228 sq. m.; pop. (1881) 1,603,259; (1911) 1,961,780; (1921) 1,787,918. It is watered by the Scheldt and the Sambre, with their affluents, and has many canals. For density of population it ranks third among the departments of France, Seine and Rhône preceding it; Lille has over 200,000 inhabitants, Roubaix 113,000, and several towns have over 30,000. The people are largely Flemish and Walloon, though the Flemish tongue is rarely heard now except in the regions of Dunkirk and Hazebrouck. The soil is fertile, the fisheries are productive, the mineral wealth very great, especially in coal; and for manufactures Nord is one of the foremost of French departments. It possessed five first-class fortresses prior to 1914, and has been the scene of many great campaigns and battles.

Nordau, MAX SIMON, son of a Jewish rabbi, Gabriel Südfeld, was born at Budapest, 29th July 1849, studied medicine there, and made a series of travels in France, Spain, and Italy, in England, Scandinavia, and Russia, establishing himself as physician at Budapest (1878), and then at Paris (1886). He wrote several works on his travels, but became known by his work proving that current ethical, religious, and political principles were but *Conventional Lies of Society* (1883); *Paradoxes*

(1886), and *Degeneration* (1893; Eng. trans. 1895), maintaining that most that is conspicuous in contemporary art, literature, and the characters of the great men of the time, is but a proof of physical and psychical degeneration. His novels (*Gefühlskomödie*, *Drohenschlacht*, &c.) have been more successful than his dramas and poems. He died 22d January 1923.

Nordenfelt. See MACHINE GUN.

Nordenskiöld, BARON NILS ADOLF ERIK, Arctic navigator, son of the superintendent of Finnish mines, was born at Helsingfors in Finland, on 18th November 1832, and studied at home and in Berlin. In 1857 he naturalised himself in Sweden, and in the following year was appointed head of the mineralogical department of the Royal Museum at Stockholm. During the next twenty years he frequently visited Spitsbergen; in 1864 he completed the measurement of an arc of the meridian there, and mapped the south of the island. After two preliminary trips to the mouth of the Yenisei, by which he proved the navigability of the Kara Sea, he successfully accomplished (June 1878—September 1879), in the celebrated *Vega*, the navigation of the North-east Passage, from the Atlantic to the Pacific along the north coast of Asia. On his return he was made a baron of Sweden (1880), and during the next five years published the results of the journey in *Voyage of the Vega round Asia and Europe* (Eng. trans. 2 vols. 1881), *Scientific Results of the Vega Expedition* (1883), and *Studies and Investigations* (1885). To Greenland he made two expeditions. Members of his party on the second occasion (1883) reached a point 140 miles distant from the east coast, but without finding the ice-free interior Baron Nordenskiöld believed to exist. Three years later he published a book on the icy interior of Greenland. He died 12th August 1901. His *Facsimile Atlas* (1889) and *Periplus* (1897) are contributions to historical geography. See Leslie's *Arctic Voyages of Nordenskiöld* (1879).

Norderney, a small treeless island, lying 3 miles off the coast of the Prussian district of East Friesland. Area, 4 sq. m. It enjoys a great reputation for sea-bathing, and in summer may have 20,000 or 30,000 visitors.

Nordhausen, a flourishing town of Prussian Saxony, pleasantly situated at the southern base of the Harz Mountains, and the west end of the fertile *Goldene Aue* ('golden plain'), on the Zorge, 48 miles by rail NNW. of Erfurt. St Blasius, one of its seven churches, contains two paintings by Cranach; and there are also a quaint town-hall, many extensive distilleries of corn-brandy or 'Nordhäuser Schnapps,' and manufactures of tobacco, sugar, leather, chemicals, &c. Dating from 874, and in 1253 created a free imperial city, Nordhausen embraced the Reformation in 1522, and in 1803 and 1815 fell to Prussia. Pop. 33,000.

Nördlingen, a town in the west of Bavaria, is situated on the river Eger, 44 miles NW. of Augsburg by rail. It has a Gothic church (restored 1880), with a high tower and fine organ, and manufactures carpets. It was an important trading centre in the Middle Ages. Here took place, 6th September 1634, the great battle in which the Swedes were defeated by the Imperialists with a loss of 12,000 killed and wounded. Pop. 8500.

Nore is a sandbank in the estuary of the Thames, 3 miles NE. of Sheerness and 47 from London. Off its east end is the floating light, which revolves 50 feet above high-water. The name is commonly applied to the portion of the estuary in the vicinity of the Nore light and sandbank. It was here that the outbreak of the fleet,

known as the 'mutiny at the Nore,' broke out on 20th May and lasted until 13th June 1797. The ringleader, Richard Parker, who had styled himself President of the 'Floating Republic,' was hanged on the 30th from the yardarm of his ship; and a few other men soon afterwards executed or flogged through the fleet. *The King's Own*, by Marryat, gives a sketch of the mutiny.

Norfolk, an important county on the east coast of England, oval in shape, and in size yielding only to Yorkshire, Lincolnshire, and Devonshire, is bounded N. and NE. by the North Sea, SE. and S. by Suffolk, and W. by Cambridgeshire, Lincolnshire, and the Wash. With an extreme length and breadth of 67 miles by 42, it has an area of 2055 sq. m. or 1,315,064 acres. Population of the administrative county with the county boroughs of Norwich and Yarmouth (1901) 476,553; (1911) 499,116; (1921) 504,293. Its coast-line, over 90 miles long, is mostly flat, and skirted by low dunes, except near Cromer, and again at Hunstanton, where cliffs, from time to time undermined by the sea, rise to a height of from 100 to 200 feet. Inland the surface is undulating, well timbered, and well watered, the principal rivers (by which, and by the London and North Eastern Railway and Midland and Great Northern Joint Railway, communication throughout the county is kept up) being the Ouse, which flows northward to the Wash, and the Bure, Yare, and Waveney, which flow into the sea near Yarmouth, and in their course link together the numerous Broads (q.v.) situate in the north-eastern district. The soil consists chiefly of light loams and sands—in places there are extensive rabbit-warrens, and with so varied a surface there is naturally an abundance of wild birds. The climate, though in the spring-time cold owing to the prevalence of east winds, is on the whole dry (average rainfall, 26 inches) and healthy. Apart from lime, chalk, and excellent brick-earth, no minerals of any importance are worked, but agriculture in all its different branches is here brought to the highest state of perfection: all the usual crops, especially turnips, swedes, and mangold, are extensively cultivated; upwards of 3400 acres are occupied as market-gardens and orchards; whilst great attention is paid to the rearing of turkeys and geese for the London markets, and on the rich marsh-lands in the extreme west of the county, as well as on the pastures bordering the various rivers, great quantities of cattle are grazed. The principal manufactures are noticed under NORWICH, and of other industries the most important is the herring-fishery connected with Yarmouth and other ports. Norfolk comprises 33 hundreds; the city and county borough of Norwich; Great Yarmouth (county borough); the municipal boroughs of King's Lynn and Thetford; 10 urban districts and 20 rural districts; and 700 civil parishes. It is mostly in the diocese of Norwich. Its parliamentary divisions are five in number, each returning one member. Towns other than the foregoing are Dereham, Diss, Downham Market, North Walsham, Swaffham, and Wymondham. In the history of the county the most notable incidents have been the settlements within its borders of the Flemish refugees and Walloons in the reigns of Henry I., Edward III., and Queen Elizabeth; and Kett's rebellion (1549). Many interesting traces of the handiwork of its former occupants are still extant in the ruins of priories at Castle Acre, Thetford, and Walsingham, in the castles of Norwich, Castle Rising (where Queen Isabella was confined a prisoner), and Caistor, in earthworks at Buckenham, Caistor, and Thetford, and in the old halls of Blickling (the home of the Boleyns), Holkham, Houghton, Oxburgh, and East Barsham. Among Norfolk

'worthies' (omitting those noticed under Norwich) are to be found the names of Gonville (founder of the college at Cambridge which bears his name), Sir John Fastolf, the Earl of Surrey, Sir Thomas Gresham, Skelton and Shadwell, Sir Edward Coke, his descendant the Earl of Leicester, Spelman (the antiquary), Sir Roger L'Estrange, Sir Cloudesley Shovel, Sir Robert Walpole and his son Horace, Thomas Paine, Windham, William Godwin, Lord Nelson, Porson, Manby, Sir Astley Cooper, Fowell Buxton, Captain Marryat, Cattermole, George Borrow, Bulwer Lytton, Dr Jessopp, and Sir H. Rider Haggard. For the Dukes of Norfolk, see HOWARD.

See the histories by Blomefield (11 vols. 1805–10), Rye (1885), White (new ed. 1890), and the 'Victoria History' (1901 *et seq.*); also A. D. Bayne's *Eastern England* (1873), Jessopp's *Arcaedy* (1887), W. Rye's *Norfolk Families* (1911–12), topographical works by W. A. Dutt, natural history works by A. H. Patterson, *Memorials of Old Norfolk*, edited by Astley (1908); F. W. Harmer's *Glacial Geology of Norfolk and Suffolk* (1911); W. G. Clarke's *Norfolk and Suffolk* (1921); J. Clayton's *Robert Kett and the Norfolk Rising* (1912), and books named at BROADS.

Norfolk, a city and port of entry of Virginia, on the right bank of the Elizabeth River, 8 miles from Hampton Roads, and 33 miles from the ocean. The city is irregularly built on low ground, and contains a city hall, mechanics' and masonic halls, custom-house, military academy, and Catholic seminary. Its large deep harbour is defended by Fort Calhoun and Fortress Monroe. A government navy yard, dry-dock, and hospital are at Gosport, a naval suburb of Portsmouth, on the opposite bank of the river. Norfolk ships considerable quantities of cotton, oysters, and early fruits and vegetables; lines of steamers connect it with New York and other cities, and three canals end here. The town was burned by the British in 1776. For the engagement between the *Merrimac* and the *Monitor*, fought off Norfolk, see NAVY. Pop. (1880) 21,966; (1920) 115,777.

Norfolk Island lies in the Western Pacific, about half-way between New Zealand and New Caledonia, 400 miles NNW. of the former. The coasts are high (mean altitude, 400 feet) and steep, and the surface generally uneven, rising in Mount Pitt to 1050 feet. The island is 6 miles long, and has an area of 13½ sq. m. The soil is fertile and well watered, and the climate healthy. The Norfolk Island Pine (*Araucaria excelsa*) grows to a height of 200 feet. Interesting endemic palms are *Howea Belmoreana* ('curly palm'), *H. Forsteriana* ('thatch palm'), and *Kentia Baueri*. Norfolk Island was discovered by Cook in 1774. Between 1788 and 1806, and again between 1826 and 1855, it was a penal settlement for convicts sent from New South Wales. In 1856 many of the inhabitants of Pitcairn Island (q.v.) were transferred thither by the British government. The island has an administrator, and advisory and executive councils under the superintendence of the Australian Commonwealth (until 1914 New South Wales). Whaling and fruit-farming are carried on, while the island is also a transpacific cable-station. Pop. (1921) 717.

Norham Castle, the Border fortress of the Bishops of Durham, on the right bank of the Tweed, 8 miles SW. of Berwick. Founded in 1121, and deemed impregnable in 1522, it has memories of Kings John, Edward I., and James IV., but is known best through *Marmion*. The picturesque ruins comprise a great square keep, 70 feet high.

Noricum, a Roman province, situated between Rætia on the west and Pannonia on the east,

and corresponding to Upper and Lower Austria south of the Danube, Styria, Carinthia, and part of Salzburg. The Roman emperor Drusus subdued the native Celtic Norici or Taurisci in 15 B.C. The name survives in the Noric Alps; see ALPS.

Normal Schools, TRAINING-COLLEGES, or **TRAINING CENTRES**, institutions where teachers are instructed in the principles of their profession and trained in the practice of it. See **EDUCATION**.

Norman Architecture, a style originated and chiefly used by the Normans. Soon after their conquest of the north of France they began to erect churches and cathedrals in memory of their victories; and, not contented with the small churches

they had done in Normandy, preserving, however, many local peculiarities of the Saxon style, which they found in the country. The chapel of St John, on the second floor of the White Tower of London, is the earliest example of pure Norman work in England, that ancient keep having been built by William the Conqueror in 1078. There are, however, many buildings, both in England and Scotland, which date from before the end of the 12th century, when the pointed style began to be used; Durham, Lindisfarne, Canterbury, Dunfermline are partially Norman, besides many other churches and castles. The Anglo-Norman is heavier than the French-Norman, the cylindrical nave piers of the English buildings being much more massive than those of French works. To relieve this heaviness the chevron, spiral, and other groovings were cut in the piers. The mouldings and forms of doors and windows are the same as those of Normandy. But whereas in France the apse at the east end is always semicircular, in England this form was gradually given up, and towards the end of the Norman style the square east end was generally adopted. For the most characteristic type of Norman domestic architecture, see **CASTLE**.

Normanby, a town in the North Riding of Yorkshire, within the parliamentary boundary of Cleveland. —Another Normanby, in the Vale of Pickering, gave the title of marquis in 1694 to John Sheffield (q.v.), Earl of Mulgrave and afterwards Duke of Buckinghamshire, as also in 1838, to Constantine Henry Phipps (1797–1863), previously Earl of Mulgrave, and a distinguished statesman. Its church has an interesting early English chancel arch.

Normandy, formerly a province of France, lying along the seaboard of the English Channel, between Brittany and French Flanders, its eastern boundaries being marked by the little rivers Eu and Epte, and its western by the Couesnon. In area it corresponded approximately to the modern departments of Seine-Inférieure, Eure, Orne, Calvados, and Manche, its capital being Rouen. It is on the whole a fertile region, with well-cultivated fields and many orchards, filled with apple-trees, from the fruit of which cider is made. The people are intelligent and industrious, and rank amongst the best and most energetic of French provincials. When the Romans were masters of Gaul this portion of the country formed part of *Gallia Lugdunensis Secunda*; after the Franks' invasion it made a constituent part of the kingdom of Neustria, and was given by Charles the Bald to the Duke of Paris. From the middle of the 9th century its coasts were harried by the vikings or sea-rovers of the north (see **NORTHMEN**); shortly after the 10th century began they established themselves in such force along the Seine that Charles, king of the Western Kingdom, was glad to make a definite agreement with their leader Rolf (Rollo, Rou) at Clair-sur-Epte in 912. Rolf, Duke of the Northmen, became the vassal of the king, but wrested his lands from the Duke of Paris, and consequently had him for an enemy all his life. Rolf at the same time became nominally a Christian, taking at his baptism the name of Robert. His successor was his son William Longsword, who declared himself King Charles's vassal in 927. His father had conquered

St John's Chapel, Tower of London.

then common in France, they desired to erect monuments worthy of their great conquests. They accordingly expanded the dimensions, while to a great extent retaining the style of the buildings they found in the north of France; though they seem also to have borrowed some of their ideas from the Rhine (see **GOthic ARCHITECTURE**).

The leading characteristics of their style were size and massiveness. They adopted the old Latin plan (derived from the Basilica) of central and side aisles; and at the east end they invariably placed a semicircular apse. They seized on the tower as a distinguishing feature, and developed it as their style progressed. The ornaments are simple and of great variety, but the most common and distinctive are the zigzag, billet, chevron, nail-head, &c. The windows and doors are simple, with semicircular arched heads—the former without tracery. The tympanum of the door-arch is occasionally filled with sculpture. The nave-arches are carried sometimes on single pillars, but more frequently, especially as the style advanced, on piers with shafts. The shafts are almost always recessed in nooks (or 'nook shafts'). Owing to the great size of the buildings the architects were unable at first to vault the main aisle, which, accordingly, had usually a wooden roof, the side aisles only being vaulted. The masonry is rude, the joints being large, and the stones generally unhewn. The style prevailed from about the beginning of the 10th century till the death of William the Conqueror, near the end of the 11th century. There are many examples in Normandy, the churches at Caen being well-known buildings of the date of William.

This style of architecture was brought into England by the Normans at the Conquest, 1066. They there extended the scale of the buildings, as

lands to the west of those originally granted to him; William added the Cotentin, or peninsula of Manche, and thus extended the duchy westwards to Brittany and the sea. This he seems to have done partly with the help of new-comers from the north, who settled there. Thus there were striking differences between eastern and western Normandy: the former rapidly adopted Christianity, the French language (*langue d'oïl*), manners, and customs, whilst the newer districts stuck sturdily to their heathen faith and customs and their native Norse tongue. Open war was waged between the rival parties not only during the lifetime of William, but in the reign of his son and successor, Richard the Fearless (943-996), who only overcame the heathen and Scandinavian party with the help of King Louis and the Duke of Paris. Louis then attempted to make himself master of Normandy—Richard being a youth—but was frustrated by Hugh of Paris, who now sided with the Normans. In 987 Hugh became king of the Western Kingdom of France; and the good understanding established between Normandy and France lasted from that time down to the accession of William, the Conqueror of England. Richard the Good, son of Richard the Fearless, began to rule in 996, and, dying in 1026, left his son Richard as his successor. It was during his reign that Nortmannia began to be substituted for Land of the Northmen; hence Normandy and Normans. The second Richard's sister Emma married, first Ethelred of England, and second Cnut (Knut) of Denmark and England; this knit the first close ties between the ruling families of England and Normandy. The third Richard was succeeded after a reign of two years by his brother Robert, who died on his way back from a pilgrimage to Jerusalem in 1035, leaving as the heir to his duchy his natural son William, at that time a boy. During William's minority the duchy was the scene of anarchy and confusion. The western portion made an attempt to assert its independence, an attempt crushed by William with the help of the king of France at Val-ès-Dunes (1047). The next twenty years are written glorious in the annals of Normandy. William ruled with vigour and prudence; he fostered the noble houses, but kept a firm hand on the nobles; encouraged the churches, yet preserved the control of church matters himself; thoroughly established the feudal system; gave countenance and support to learning (Lanfranc, Anselm); and favoured the building of magnificent abbeys. He also waged war with the Count of Anjou, his southern neighbour, for the county of Maine, and conquered it in 1063; and even fought against the king of France, who gave assistance to rebels against William's rule. After the conquest of England (q.v.) Maine revolted and had to be subdued again, William's son Robert rebelled against him in Normandy, and a war broke out with France, in which William (q.v.) lost his life. The incapable Duke Robert mortgaged his duchy to his brother William Rufus, and went crusading to the East. After his return he was defeated and imprisoned by his brother Henry I., who ruled Normandy till his death (1135), notwithstanding the efforts of Robert's son William to dislodge him. After the accession of Stephen in England Matilda's husband, Geoffrey of Anjou, gradually made himself master of Normandy (1139-45), but after reigning five years he resigned it to his son, afterwards Henry II. of England. Richard I. and John were the next dukes. But the duchy was taken away from John by the king of France (1203-4), on the plea that as the murderer of his nephew Arthur he (John) had forfeited his French fiefs. The claim to the title was, however, only formally renounced by Henry III. in 1259. Twice subsequently

Normandy was in English hands; Edward III. conquered it in 1346, and Henry V. in 1417-18; but the English were finally driven out in 1450. The Channel Islands (q.v.) are a remnant of the Norman possessions still belonging to the descendants of the Norman kings of England. For map, see France in provinces. See also ENGLAND, SICILY, NORMAN ARCHITECTURE, NORTHMEN.

CUSTOMARY LAW OF NORMANDY.—The duchy was governed by customary law, which grew up principally out of local usages; at first it was the same as the customary law of England. Even down to the present day the law administered in the royal courts of the Channel Islands is virtually the old customary law of Normandy. One feature survives in the Cry of Haro (q.v.). This ancient customary law of Normandy seems to have been collected in writing on three separate occasions. The earliest collection was apparently written down by private persons in 1200 and about 1220, and had no official character; the third collection (1585) is a revised edition of the second, the *Grand Coutumier*, completed early in the 14th century.

See French histories by Dumoulin (1631), Goube (1815), Depping (1835), Barthélemy (1857); Freeman, *Norman Conquest* (5 vols. 1877); Palgrave, *History of Normandy* (4 vols. 1878); Planché, *The Conqueror and his Companions* (1874); Powicke, *The Loss of Normandy* (1913); C. H. Haskins, *Norman Institutions* (1918).

Normanton, a town in the West Riding of Yorkshire, by rail 3 miles NE. of Wakefield and 10 SE. of Leeds, an important railway junction and seat of coal-mining. Pop. 16,000.

Norns, the *Paræ* of Scandinavian mythology, were three maidens, by name Urd, Verdandi, and Skuld—i.e. Past, Present, and Future. They sit by the well of Urd, under the world-tree Yggdrasil in Asgard, and there determine the fate both of gods and men. Besides these three there are many inferior norns, both good and bad, answering to the genii of classical mythology; to such are attributable the unequal destinies of men in the world. Women who possessed the power of prediction or magic also bore this name.

Norristown, capital of Montgomery county, Pennsylvania, on the left bank of the river Schuylkill (crossed by three bridges to Bridgeport), 17 miles by rail NW. of Philadelphia. It contains a fine marble court-house, a state asylum for the insane, a number of cotton-mills and woollen-factories, rolling-mills and foundries, flour-mills, and manufactories of glass, tacks, &c. Pop. (1880) 13,063; (1910) 27,875; (1920) 32,319.

Norrköping, an important manufacturing town of Sweden, at the head of the Bråvik, 113 miles by rail SW. of Stockholm, is a well-built modern town. Founded in 1384, it has been several times destroyed by fire. The rapid river Motala, which connects Lake Vetter with the Bråvik, and which is spanned by several bridges, gives water-power; there are cloth-mills, cotton spinning and weaving, manufactures of sugar, paper, and tobacco, and shipbuilding. Here Charles IX. and Gustavus IV. were crowned. Pop. 60,000.

Norrland. See SWEDEN.

Norse. See ICELAND, SCANDINAVIA, NORTHMEN, NORWAY, &c.

North, a family famous in the history of England, the most illustrious members of which were three of the sons of Dudley, fourth Baron North of Kirtling in Cambridgeshire, all of whose lives fortunately were written by their youngest brother Roger, who also bequeathed to posterity an interesting and characteristic, but unfinished, autobiography. These have all been collected by Dr Jessopp (3 vols. 1890).—SIR EDWARD NORTH (1496-

1564) was famous as a lawyer, and was created Baron North of Kirtling in Cambridgeshire in 1554. His second son was SIR THOMAS NORTH, of whose life we know but little save that he probably died in 1601. In 1579 appeared the first edition of his memorable translation of Plutarch. This work, a translation from the French of Amyot, remains a noble monument of English, and was beyond doubt one of the fountains from which Shakespeare drew his knowledge of ancient history. There is an admirable edition of the portions relating to Shakespeare by Professor Skeat (1875). Other translations by North were *The Diall of Princes*, from a French version of Guevara (see EUPHUISM), and *The Morall Philosophie of Doni*, from the Italian (1570; new ed. by Joseph Jacobs, 1888).—CHARLES, the eldest son of the fourth Baron North, was created Lord Grey of Rolleston, but on the death *s.p.* of his son, William, sixth Baron North (1734), the barony of Grey ceased, and that of North devolved upon his cousin, Francis, third Baron Guilford. He was created Earl of Guilford in 1752, and his son, the second Earl of Guilford and eighth Lord North, was the famous statesman under George III. The third earl had only three daughters, between whom the barony of North of Kirtling fell into abeyance on his lordship's death in 1802, until in 1841 it vested in Susan, Baroness North (1797-1884), whose son, William-Henry John, succeeded as eleventh Baron North in 1884. The other honours of the third earl devolved upon his brother, Francis, fourth earl; and next on another brother, Frederick, fifth earl; on whose death in 1827 the earldom reverted to his cousin, Francis, sixth earl; who was succeeded by his grandson, Dudley-Francis, seventh earl; and he in his turn, in 1885, by his son, Frederick-George, eighth Earl of Guilford.—FRANCIS NORTH, second son of Dudley, fourth Baron North, was born 22d October 1637. He had his education at Bury and St John's College, Cambridge, studied law at the Middle Temple, and was called to the bar in 1655. He worked hard, was judicious in his drinking, and more than prudent in his marriage, and was knighted and made Solicitor-general in 1671, and Attorney-general in succession to Sir Heneage Finch but two years later. In 1674 he became Lord Chief-justice of the Court of Common Pleas. As far from being the despicable creature of Macaulay's picture as the saint and sage of his brother's eulogium, he knew how to make interest for himself, and quickly became a privy-councillor, and in 1682 Lord-keeper of the Great Seal, and Baron Guilford (September 1683). We know of his love for music, his kindness to his brothers and sisters, his dislike of witchcraft trials, and his distrust of all the many plots of the time. After the king's death he was much vexed by the intrigues and insolence of Sunderland and Jeffreys, but soon after died, 5th September 1685.—SIR DUDLEY NORTH, the third son, was born 16th May 1641, and, like his brothers, educated at Bury. Even at school he was a trader, and at an early age he was bound to a Turkey merchant in London. Ever the industrious apprentice, he yet solaced himself with cock-fighting and swimming. He made a voyage to Archangel, next to Smyrna, where he settled for some years in trade. Afterwards he settled in Constantinople, returning to England some years after with a considerable fortune, which he continued to increase by keeping an interest in the Levant trade. He became one of the sheriffs of London, and was pliant enough in the interest of the crown. He was knighted, married the widow Lady Gunning, and was appointed a Commissioner of Customs, next of the Treasury, then of the Customs again. Under James II. he sat in parliament for Banbury, and after the Revolu-

tion made but a sorry defence of his actions as sheriff. He was a keen-eyed observer of men and manners, had great mechanical genius, a passion for architecture, and quite extraordinary ability as a financier. Indeed, his *Discourses upon Trade* (1691) anticipate in a striking manner some of the ideas of Adam Smith. He died 31st December 1691.—DR JOHN NORTH, the fifth son, was born in London, 4th September 1645, was educated at Bury, and entered Jesus College, Cambridge, in 1661, becoming fellow there in 1666. He was strangely timid, yet a severe student, solacing himself by book-buying and by keeping great spiders in wide glass bottles. He succeeded Barrow as Master of Trinity College in 1677, became clerk of the closet to Charles II., and died, after a long and grievous sickness, in April 1683.—ROGER NORTH, the sixth and youngest brother, was born at Tostock in Suffolk, 3d September 1653, educated at Bury and Jesus College, Cambridge, entered the Middle Temple, and under the influence of his brother the lord-keeper, soon rose to a lucrative practice at the bar. At the Revolution his hopes of advancement were closed, and, casting in his lot with the nonjuring party, he retired to his estate of Rougham in Norfolk, where he indulged the family passion for building, and acted as trustee for his great brother's estate at Wroxton. In 1696 he married, and lived henceforth the life of a country gentleman and virtuoso. He died 1st March 1734. His three hyper-eulogistic biographies, his autobiography, with its amusing prejudices, his *Examen* (1740) of Dr White Kennet's *History of England*, and his *Memoirs of Music* (1846) give him a place in English literature.—FREDERICK NORTH, eighth Lord North and second Earl of Guilford, a famous English minister, was born 13th April 1732, and educated at Eton and Trinity College, Oxford. When only twenty-two he entered the House of Commons, and he was made a Lord of the Treasury in 1759, having inherited the Tory politics of his ancestors. On the death of Charles Townshend in 1767 he was made Chancellor of the Exchequer and leader of the House of Commons, a post for which he was well qualified by his eloquence, good-humour, wit, and readiness of resource, even against such antagonists as Fox and Burke. In 1770 he succeeded the Duke of Grafton as prime-minister. North was largely responsible for the measures that brought about the loss of the American colonies; as a minister he was too ready to surrender his own judgment to that of the narrow-minded and obstinate king. Indeed, North was called by Horace Walpole the *ostensible* minister; the *real* minister was George III. In 1778 he renounced the right of taxing the colonies, already seeing that the war was hopeless, and in 1782 he resigned. With North's retirement came to an end the king's scheme of governing the country by his own will, and ruling the House of Commons by thinly-disguised corruption. North was succeeded by the Marquis of Rockingham, on whose death Lord Shelburne became premier. Fox's dislike of the terms of peace with America led him to enter into a coalition with North, whom he had for so many years inveighed against as a minister without foresight, treacherous, vacillating, and incapable. North and Fox took office under the Duke of Portland in 1783, but the coalition destroyed Fox's popularity, and the Portland administration only lasted a few months. North was afflicted by blindness during the last five years of his life. He succeeded to the earldom of Guilford in 1790, and died 5th August 1792. See his *Life* by R. Lucas (1913).

North Adams, a manufacturing city of Massachusetts, picturesquely situated on the Hoosac River, near the west end of the Hoosac Tunnel, 143 miles by rail W. by N. of Boston. It has a

large number of woollen and cotton mills, shoe and print-cloth factories, a foundry, &c. Pop. 22,000.

Northallerton, the capital of the North Riding of Yorkshire, 30 miles NNW. of York. It has a town-hall (1874); a fine cruciform church, Norman to Perpendicular in style; a cottage hospital (1877); and sites of a Roman camp and a Norman castle of the bishops of Durham. At Standard Hill, 3 miles N., was fought, on 22d August 1138, the great battle of the Standard, in which Archbishop Thurstan routed David I. of Scotland, and which got its name from the banners of SS. Peter, John of Beverley, and Wilfrid, which were displayed in the English host. Pop. 4800.

Northampton, the capital of Northamptonshire, and a county, parliamentary, and municipal borough, is seated on rising ground on the left bank of the river Nen, 66 miles NW. by N. of London and 50 SE. of Birmingham. It has a fine town-hall (1861-64), to which other municipal offices have been added; a county hall, noticeable for its decorated ceiling; two museums, a public library, and schools of science and art (enlarged 1889); several large hospitals; a theatre; infantry barracks; and numerous churches, the most interesting of which are St Peter's (Norman), St Sepulchre's (Norman and Decorated, one of the few remaining round churches in England), All Saints' (rebuilt subsequent to 1675, but with a fine west tower partly Norman), and St Giles' (cruciform). The principal manufacture is that of boots and shoes, the town being the English centre of that industry; a considerable trade is carried on in the dressing of leather, some lace is made, extensive breweries are in operation, and there are iron-foundries and flour-mills. On the outskirts of the town is a fine racecourse, on which meetings are held annually in April and November. Pop. (1801) 7020; (1831) 15,351; of the municipal borough (1921) 90,923, and of the parliamentary borough, which returns one member, 75,000.—Of the many stirring events of which Northampton has been the theatre, the principal are its burning by the Danes (1010); the rebuilding, and erection of its castle (of which few traces now remain) by one Simon de St Liz (c. 1075); its siege by the barons (1215), when garrisoned for King John; the establishment of its university (1260), which was abolished some few years later; the conclusion of a treaty (1318) by which the independence of Scotland was formally recognised; the holding of many parliaments; royal visits by Richard I. (in whose reign a royal mint was established here), John, Henry III. (who here received homage from Alexander II. of Scotland), Edward I., Queen Elizabeth, and Charles I.; a battle (10th July 1460) between Henry VI. and the Yorkists, in which Henry was defeated and made prisoner; a visitation of the plague (1637), which in five months claimed 500 victims; the mustering in 1642 of the parliamentary forces under Essex on the outbreak of the Civil War; and a great fire (1675).

See the *Records of the Borough of Northampton* (2 vols. 1898), and Cox and Sergeantson's history of the church of St Sepulchre (1898).

Northampton, capital of Hampshire county, Massachusetts, stands near the west bank of the Connecticut River (here crossed by a bridge to Hadley), 103 miles by rail W. of Boston and 3 miles NW. of Mount Holyoke. It contains a state lunatic asylum, the Clarke Institute for deaf-mutes, a public library, housed in the handsome Memorial Hall, and Smith College for women. The manufactures are of importance, and include silk, woollen goods, sewing-machines, cutlery, baskets, brushes, jet ornaments, &c. Pop. 22,000.

Northamptonshire, or **NORTHANTS**, a mid-land county of England, 67 miles long, and 25 at its broadest. Area (including the Soke of Peterborough), 998 sq. m., more than half pasture. Pop. (1801) 131,757; (1841) 199,208; (1891) 302,184; (1911) 348,515; (1921) 349,363 (whereof 46,954 were in the Soke of Peterborough). In the north-east near Peterborough the county is flat, and forms part of the Bedford Level (q.v.), but elsewhere the surface is undulating, the highest ground—about 800 feet above the sea-level—being found near Daventry. It is traversed by the London, Midland, and Scottish and the London and North-Eastern railways, and communication by water is maintained by the Nen and the Welland, which are the chief rivers, as also by the Grand Junction, Union, and Oxford canals. The soil, a black, peaty mould in the north-east, and a brown loam on the uplands, is on the whole very productive. Corn and green crops are largely grown, but the area of land devoted to those crops decreases, while more and more land is devoted to stock-raising. On the broad pastures many cattle are grazed, and dairy-farming is carried on, but, although Northants is a great hunting county, the breeding of horses is not much encouraged. The principal minerals are limestone, which is quarried in the north-east, and iron ore of excellent quality, which is found near Kettering, Wellingborough, and Thrapston, and in the neighbourhood of Stamford. Part of the ore is smelted within the county. The manufactures are considerable apart from those noticed under Northampton. The county comprises twenty hundreds, the municipal boroughs of Brackley, Daventry, Higham Ferrers, Northampton, and Peterborough. Northamptonshire is included almost entirely in the diocese of Peterborough. The Soke of Peterborough is a separate administrative county. The parliamentary divisions are four, each returning one member. In history the principal incidents connected with the county, omitting those noticed under Northampton (its capital), have been the battles of Edgecote (1469) and Naseby (1645), the beheading of Mary Queen of Scots at Fotheringhay Castle (1587), and the imprisonment of Charles I. at Holmby House (1647). Of its natives, besides Richard III. and (perhaps) Catharine Parr, the best known are Archbishop Chichele (the founder of All-Souls' College at Oxford), Sir Christopher Hatton (the courtier), Catesby (of Gunpowder Plot renown), Thomas Fuller, James Harrington, Bishop Cumberland, Dryden, Charles Montagu, Earl of Halifax, William Law, Gill and Carey (the eminent Baptists), Doddridge (the Nonconformist), James Hervey, Cartwright ('the father of Reform'), Dr Paley, William Lisle Bowles, Clare (the peasant poet), the Earl of Cardigan (leader of the Balaclava charge), and Dean Mansel.

See histories by Bridges (1791), Baker (1822-41), Dryden (1903), and the 'Victoria History' (1902 & seq.); and topographical work of H. A. Evans, *Highways and Byways in Northamptonshire and Rutland* (1918).—Hampshire (q.v.) is the county of Southampton.

North Berwick, a fashionable watering-place of Haddingtonshire, at the entrance to the Firth of Forth, 23 miles ENE. of Edinburgh and 10 by water SSE. of Elie in Fife. It has a ruined nunnery. Behind it rises conical North Berwick Law (612 feet); and westward and eastward stretch splendid golf-links. Tantallon Castle, 3 miles E., fronting the Bass Rock (q.v.), is a magnificent ruin, finely described in Scott's *Marmion*. A stronghold of the Douglasses, it resisted James V. in 1528, but in 1639 was 'dung down' by the Covenanters. Robert III. made North Berwick a royal burgh, and till 1885 it

returned, with Haddington, &c., one member to parliament. Pop. 4500.

Northbrook. See **BARING**.

North Cape, reckoned the northernmost point in Europe, in $71^{\circ} 10' N.$ lat., is on the island of Magerö. The northernmost point on the continent is Cape Nordkyn ($71^{\circ} 6' N.$ lat.), 6 miles farther south than the North Cape, and some 45 miles to the east of it.

North Carolina, popularly known as 'Old North State' and as 'Turpentine State,' is one of the thirteen original United States of America, on the Atlantic seaboard, south of Virginia, in $33^{\circ} 50' - 36^{\circ} 33' N.$ lat., and $75^{\circ} 27' - 84^{\circ} 39' W.$ long. Length 500, breadth 186 miles; area, 52,426 sq. m. —larger than that of England.

The eastern part of the state is low, and in some parts swampy, the central part undulating, and the western mountainous; but everywhere, except in limited areas in the eastern section, the soil is remarkably fertile and the climate salubrious. The highest mountains in the United States east of the Mississippi are in North Carolina, more than fifty exceeding 6000 feet in altitude—Mitchell's Peak (6711 feet) the highest. Most of these are clothed to their tops with thick forests, but some have prairie-like summits covered with deep turf. All this picturesque region, known as 'the Land of the Sky,' is a favourite resort in summer for southerners and in winter for northerners.

North Carolina is rich in minerals. Some gold is still mined. A branch U.S. mint was established at Charlotte in 1838, and has since 1873 been continued as an assay office. Silver occurs associated with lead in Clay and Davidson counties, and zinc in the latter county. Iron is widely disseminated in the form of specular ores, hematites, and magnetites; copper and plumbago also are found in many counties. Coal of excellent quality has been profitably mined in the vicinity of Deep River, and is abundant, too, near the Dan River. In the west there are valuable deposits of corundum and extensive beds of mica, in the production of which North Carolina ranks first among the states; and more than 150 species of gems, &c. are found in the state, including the rich 'hiddenite' or lithiopyroxene, which is not known to occur elsewhere. Granite and marble abound in some localities, and there are valuable phosphate beds in the eastern section.

Cotton is by far the most valuable crop. Tobacco, maize, hay, and sweet potatoes are the next most valuable products of the soil. One of the chief industries in eastern North Carolina has long been the production of tar, rosin, and spirits of turpentine from the forests of long-leaved pine (*Pinus palustris*) and allied species. The manufacturing industries until 1880 were limited, but since that date North Carolina has assumed a premier position among the states for the number of its cotton-mills; tobacco-factories have been enlarged, and in 1888 the first silk-factory in the southern states was established. Furniture-making is important, while the state ranks tenth as regards output of lumber. Fisheries constitute a profitable industry along the coast.

North Carolina contains 100 counties, and returns ten representatives to congress. It has about 5500 miles of railway. The chief port and largest city is Wilmington, the capital Raleigh. Parts of the state are deficient in good schools, but there are excellent graded schools in the principal towns. Besides several denominational colleges, there is a state university (1795) at Chapel Hill, and a state agricultural college was established at Raleigh in 1889. There are asylums for the insane at Goldsboro, Raleigh, and Morganton—the first for negroes only; and provision is also made by the state for the blind and deaf-mutes, both white and black.

History.—In 1584 Raleigh's first expedition landed on Roanoke Island, and found the natives kindly disposed. In 1585, 1586, and 1587 Raleigh planted colonies on the island, but the first returned with Drake in 1586, and the others were destroyed. In 1629 Charles I., on the strength of Cabot's discovery, granted to Sir Robert Heath the territory, also claimed by Spain and called by them Florida, from lat. 30° to 36° as *Carolana Florida*. By the English it was called both Carolana and Carolina. In 1653 a colony from Virginia settled on the banks of the Roanoke and Chowan rivers: this was the first permanent settlement in North Carolina. In 1663 Charles II. granted the region across the continent between lat. 31° and 36° to eight of his favourites, under the name of Carolina. In June 1665 the king extended the limits of Carolina to 29° on the S. and to $36^{\circ} 30' N.$ The proprietors, 'to avoid erecting a numerous democracy' in Carolina, adopted a utopian form of 'fundamental constitutions,' prepared by John Locke and Shaftesbury, which recognised a nobility of landgraves and cassiques. The eldest proprietor was palatine, and the other seven had high-sounding titles. The people opposed this scheme, and in 1729 the king bought out the claims of the proprietors for £2500 each, and North Carolina became a royal province. Under the administration of the second royal governor, Gabriel Johnston (1734-53), the colony increased in population from 14,000 to 45,000, and became very prosperous. The arbitrary rule of Governor Dobbs (1754-66) and Governor Tryon (1766-73) served to intensify the dislike of the people to the taxation policy of parliament; and when the colonial assembly at Wilmington protested against taxation without representation it was dissolved by Governor Tryon. The Mecklenburg Convention met at Charlotte and adopted a declaration of independence on 20th May 1775. The early years of the war (1775-83) were marked by bitter local and partisan conflicts between Whigs and Tories. In the years 1779-81 North Carolina furnished about one-tenth of the American army, the war being transferred to the south. It ratified the federal constitution, 21st November 1789. It was the last of the eleven Confederate States to pass in convention an ordinance of secession, 21st May 1861, which was not submitted to the people. The capture of Fort Fisher in January 1865 led to the federal occupation of Wilmington, the advance of the union forces on Raleigh, and the surrender of General Johnston, which practically ended the war of secession. Presidents Jackson, Polk, and Johnson were natives. Pop. (1800) 478,103; (1840) 753,419; (1880) 1,399,750; (1900) 1,893,810; (1920) 2,559,123. See histories by Hawks (1857), Lawson (1860), Moore (1880), and Raper's *North Carolina, a Study in Colonial Government* (1904).

Northcliffe, ALFRED CHARLES WILLIAM HARMSWORTH, 1st VISCOUNT, son of a barrister, was born near Dublin in 1865. His parents coming to England, he was educated at Stamford Grammar School and Henley House School, West Hampstead. He turned early to journalism and was with a firm of publishers at Coventry till 1889, when he established a similar business of his own in London. *Answers* (1888) proved a success, to be followed in 1896 by the *Daily Mail*. Created Baron Northcliffe in 1905, he continued to add to the structure of the Amalgamated Press, obtaining possession of the *Times* in 1908. During the Great War his influence was powerful not only in the press but also in private political circles. The title of viscount was bestowed on him in 1917, and, after a world tour in 1921, he died in August 1922. See Max Pemberton, *Lord Northcliffe*, and article **NEWSPAPERS**.

Northcote, JAMES, R.A. (1746–1831), son of a Plymouth watchmaker, painted many historical paintings, was eminent as a portrait-painter, wrote the *Memoirs of Sir Joshua Reynolds* (whose assistant he was), a *Life of Titian*, and two illustrated books of fables. See Hazlitt's *Conversations* with him (new ed. by Gosse, 1894), his with James Ward (ed. Fletcher, 1901), and Gwynn's *Memorials of an Eighteenth-century Painter* (1898).

Northcote, SIR STAFFORD. See IDDESLEIGH.

North Dakota, one of the northernmost of the United States, ranking sixteenth in area and thirty-sixth in population. It is an elevated land of plains and prairies, bounded on the north by the Canadian provinces of Manitoba and Saskatchewan, by Minnesota in the east, Montana in the west, and South Dakota in the south. In the neighbourhood of the Red River, which forms the state's eastern frontier, there is a narrow but extremely fertile plain. Thereafter the land rises, steeply in the north, to the higher and more westerly region of prairies, also a prolific agricultural district. From the glacial and alluvial deposit found here, it has been surmised that during the Silurian age a shallow sea or saline lake must have passed over it, while evidence seems to indicate its partial submergence at the end of the glacial period. The enclosed and saline Devil's Lake is the only remaining lake worthy of note. The more lofty plains of the Coteau du Missouri occupy the western half of the state, and through them, in a roughly south-easterly direction, the Missouri makes its way, attended by numerous tributaries. The mountains are not conspicuous, consisting chiefly of the Pembina Mountains in the north-east, the Turtle Mountains in the north, and the high ground of the south-west, where are the celebrated Bad Lands, the soft soil of which is fancifully moulded by the wind and the heat of the burning lignite coal which abounds here. In the western portion of the state vegetation suffers from the rigours of the climate, which is more extreme than in any other state, although healthy and pleasant enough for human habitation. State efforts have been exerted to promote afforestation, there being a lack of timber.

North Dakota is essentially an agricultural state; the rural population exceeds the urban more than sixfold. In 1923 nearly 60,000,000 bushels of wheat were produced, flax-seed, maize, oats, and barley also figuring very prominently. Fruit-growing gives promise as an occupation, and stock-raising and dairy-farming are rapidly becoming very important. The Bad Lands, although of little value for crops, afford good grazing. The rainfall is low but generally sufficient; irrigation is practised, especially at Williston, where 80,000 acres come under a U.S. Government irrigation scheme. Manufactures other than those directly connected with agriculture (flour and grist milling, butter-making, &c.) are not important. Lignite coal is mined to a considerable extent, especially near Bismarck, and used for local purposes, while clay for making bricks and pottery is found in the south-west. Railway enterprise has contributed largely to the settlement of the country; the total mileage is over 5300. Both the Missouri and the Red River are navigable to light craft.

The supremacy of the agricultural interest in North Dakota has had some interesting results from a social and economic point of view, especially as regards the introduction of state-owned elevators, flour-mills, and the institution of a state bank. The devices of initiative and referendum were made applicable to all legislation in 1914. Educationally the state is well-equipped, having a state university at Grand Forks, numerous normal and

several agricultural schools, and Indian schools at Wahpeton and Bismarck. There are reform schools at Bismarck and Mandon and asylums at Jamestown and Grafton.

History.—Traders of the Hudson Bay and North-West Fur Companies had outposts in this region before the end of the 18th century, and Lord Selkirk instituted a settlement at Pembina by mistake in 1812. But not until the 'sixties, when the Dakotas became a territory of the United States, did they assume anything like their present form. The boundaries continued to be modified by the formation of adjacent states, and in 1889 it was decided to separate the northern and southern portions of Dakota. These two states were admitted into the Union shortly afterwards. The earlier seat of government was Yankton, but in 1883 it was transferred to Bismarck, the present capital. Population of North Dakota (1890) 190,983; (1910) 577,056; (1920) 646,872. The chief towns are Fargo (21,961); Grand Forks (14,010); Minot (10,476); and Bismarck (7122). Area of state, 70,837 sq. miles.

Northern Territory, a territory of the Commonwealth of Australia (till 1911 of South Australia) between Queensland and Western Australia, north of 26° S. lat. The country is hot and dry, a sandy tableland in the south, pastoral in the north. Agriculture and mining are practicable, but little developed. There is fine scenery. The north coast has good harbours and a number of islands (Melville, Bathurst, Groote Eylandt, &c.). From Darwin, the capital, a railway runs to Pine Creek, to be connected some day with Oodnadatta and Adelaide. Area, 523,620 sq. m.; pop. (1921) 3867, besides some 7000 aborigines.

Northmen, or NORSEMEN, were the sea-rovers who came from the north—Denmark, Norway, Sweden. Bolder navigators than even the Phœnicians of old, they sailed east, west, south, and even north into the Arctic Ocean, to fight for fame, to gain wealth, to plunder, and to slay. We nowadays should call them pirates; they called themselves vikings (a word perhaps of Anglo-Frisian origin, which may mean 'camp-men'), and believed that these expeditions were the noblest and most honourable work they could put their hands to. They held too that the best title, in the legal sense, to property was given by winning it with the sword. This gained them the highest respect and influence, and was the surest guarantee of political power. There were likewise powerful economic and political causes co-operating with these to send forth, from the middle of the 8th century to the 13th, and even later, these thronging swarms of Northmen. The natural resources of the lands they dwelt in were very inadequate in proportion to population. The system of land tenure, based on the indivisibility and absolute ownership of the family estate, frequently imposed galling restraints upon the younger sons, especially the more restless and high-spirited among them. Hence they spent the summer in quest of fame and booty in distant lands; but generally came home again in the autumn, to pass the winter in the enjoyment of the good things they had earned. Still stronger impulses were given to these expeditions when the more powerful chiefs (kings) at home began to subdue their weaker rivals, and the separate kingdoms (Norway, Denmark, Sweden) began to take definite shape, under such strong rulers as Harold Fairhair (Haarfager) and Cnut. Many of the free odal proprietors, rather than become the feudal vassals of the conquerors, preferred to abandon their homes, and go and conquer new lands for themselves elsewhere. These strong rulers, moreover, sternly put down the

intestine conflicts in which the Northmen delighted; consequently to get their fill of fighting they were obliged to go abroad.

A favourite plan of the weaker viking chiefs was to lie in wait up some small creek or river-mouth, or behind the shelter of some island, and thence suddenly dart out upon a passing vessel. The larger fleets boldly invaded a district, plundered the inhabitants, slew them if they offered resistance, or carried them off as slaves if they did not, harried the open country, rifled the churches and monasteries—which always yielded the greatest stores of gold and silver—and not infrequently burned them to the ground, as they did the strong cities they took and sacked. Being heathens, worshippers of Thor and Odin, they had no qualms of conscience as to sacrilege, and stood in no awe of the threatenings of the church. One viking fleet would even challenge another to fight it for fighting's sake only. The vessels they sailed in were comparatively small and light of draught, so that they were able to penetrate a long way up the rivers, sometimes into the heart of a country; and as the Northmen were resistless in arms and unrelenting in their wrath, their mere appearance was often sufficient to paralyse an entire district with panic terror. In many churches a special petition, 'From the fury of the Northmen, O Lord, deliver us,' was recited in the litany. But these sea-rovers were also keen traders: on many occasions they first requested permission to land and trade peacefully with the inhabitants, and only when their trading was done did they begin to plunder. There were several recognised trading-places along the shores of the Baltic, and some on the North Sea, which were visited not only by legitimate merchants from England, Flanders, Italy, the East, but also by vikings who had slaves, and gold and silver, and other less valuable booty to dispose of.

The viking age is divisible into two periods: during the first adventure and plunder were the chief incitements—this lasted until the middle of the 9th century; the second was the period of permanent conquests, in Ireland, France, England, South Italy. The sea-rovers made their first recorded attack upon England in 787, in Wessex, and first began to raid along the shores of Frisia, Flanders, and France towards the end of the century. These bands came from Denmark, but may nevertheless have been Norwegians. During the first half of the next century the depredations of the Northmen were more terrible than ever, especially in Frisia and Flanders, during the periods 834–837 and 845–850. They had also gone farther south: in 820 a band reached Aquitaine; fifteen years later another band plundered the French island of Noirmoutier; in 843–844 a fleet sailed up the Loire and Gironde, visited Galicia (Spain), and steered up the Guadalquivir and fought the Moors. From about the middle of the century bodies of Northmen established themselves in permanent camps at the mouths of the French rivers, and repeatedly ascended them on their errands of plunder and slaughter. Three times they took Paris and stripped it of its wealth (845, 857, 861); but the most famous siege took place in 885–886. In 859 and 860 an exceptionally adventurous fleet entered the Mediterranean, ravaged the coasts of Spain and Mauretania, and Majorca, spent the winter at the mouth of the Rhone, and in the following summer ruthlessly attacked the coast towns of Italy, especially Luna (near Carrara), thinking it was Rome. Yet Flanders and the north of France suffered most during the thirty-six years from 876 to 912. During all this period a large army, or even armies, dominated the coast districts from the Rhine to Brittany, quartering themselves in

entrenched camps, and not only routing time after time the armies of the weak kings of Austrasia and Neustria, and their still weaker vassals, but even making disastrous raids far into the interior—to Coblenz, Soissons, Sens—and extorting from kings, dukes, counts, and towns large sums in gold and silver as the price of abstaining from hostilities. The chiefs of these formidable bands were Björn Ironside, Hasting, Siegfred, Godfred, and Rollo or Rolf. Detachments of the main body crossed over more than once to England, where, however, Alfred was a match for them. Rollo (Rou) is probably the same as Rolf the Ganger; if so, he was the son of a chief of the west coast of Norway, and was outlawed by Harold Fairhair shortly after 872. In 912 Charles the Simple of France, seeing that it was hopeless for him to drive away his dangerous and pertinacious foemen, thought it best to disarm them against himself, and at the same time arm them against new-comers, by allowing them to settle in his kingdom, a plan adopted by other rulers before. Accordingly at Clair-sur-Epte he agreed to cede to Rollo the district bounded by the Channel, the Seine, and the Epte, on condition that he would become his man or vassal, and be baptised a Christian. Rollo accepted the terms, and thus acquired the nucleus of the duchy of Normandy (q.v.). There the name Northmen was softened into Normans, a name celebrated in history not only in virtue of the conquest of England by Duke William, but also because of their exploits in Italy and Sicily, and the East. See GUISCARD and SICILY.

The earliest serious attacks upon England were made in 793 and 794, when Lindisfarne and Jarrow monastery were sacked and Northumberland ravaged. It was about the same time that the sea-kings of Norway began to cross the 'Western Sea' and sail as far as the Syderöer or South Islands—i.e. the Hebrides, the Western Isles of Scotland, and Man (q.v.)—and to Ireland, probably utilising the Faeroe (q.v.) and Shetland (q.v.) Islands as resting-stages. They sacked Iona (Hy) in 802 and again in 806, slaying most of the monks. Their visits to Ireland were particularly numerous after 807, and brought great woes upon the unhappy island. A chief named Torgisl, a Norseman, conquered most of north Ireland shortly after 840. In or a little before 852 a fleet of Danes arrived and disputed fiercely with the Norsemen, or, as the Irish called them, the Eastmen; but in the year quoted Olaf the White of Norway founded the Scandinavian (chiefly Danish) kingdom of Dublin, which lasted three centuries or more, whilst two of his followers created the separate kingdoms of Waterford and Limerick (see IRELAND). The Faeroe, Orkney, and Shetland Islands seem to have been frequently visited by Norsemen after 825, and were permanently colonised during the next quarter of a century. Iceland (q.v.) was discovered and colonised by the same people between the middle and end of the century; and from Iceland they ventured still farther west, and made settlements in Greenland (q.v.), and even visited Vinland (q.v.) in North America. The viking raids on England were incessant after 833, but were checked for a time by the great slaughter inflicted by Ethelwulf at Ockley (Surrey) in 851. Fifteen years later they began again, and this time assumed the character of a serious invasion, the invaders being almost exclusively Danes. They made themselves absolute masters of the northern, and more especially the eastern, portions of the island, notwithstanding the heroic efforts of Alfred and his son Edward. The struggle is sketched under England (q.v.).

By the middle of the 8th century the Norwegians

had discovered the sea-route to the White Sea by rounding the North Cape. On several occasions down to 1222 they sailed up the Northern Dwina and plundered the people of Bjarmeland or Permia. The most important event in viking history on the east side of the Baltic happened in 862. The Slav (perhaps rather Germanic Russi) tribes who dwelt south of Lake Ladoga as far as the Southern Dwina invited three Scandinavian chiefs (probably from Sweden), brothers, of whom Rurik became the most influential, to go and rule over them. They established themselves at Holmgaard (Novgorod) and laid the foundations of the kingdom of Gardariki, out of which grew the subsequent Russia (q.v.), that was ruled over by Rurik's descendants down to 1598. About the same time two other Scandinavian chiefs formed the nucleus of another state at Könugaard (Kiev); and, sailing thence down the Dnieper, they threatened Constantinople, which was only saved by a sudden storm scattering the fleet of the Northmen or Värings (Varangians), as they were called by the Slav Russians and the Greeks. Three times during the first half of the 10th century these adventurers appeared before the capital of the Eastern empire, and on two occasions (907 and 945) went away carrying with them heavy sums, paid by the emperors to save the city from assault. Igor, the son of Rurik, who commanded two of these expeditions, even launched his fleet on the waters of the Caspian, and carried the terror of the Northmen's name among the Mohammedan dwellers on its shores. The expeditions of the Värings gradually ceased after Vladimir introduced Christianity into his dominions in 988. Nevertheless for many years these Scandinavian rulers in Russia surrounded themselves with stout and trusty warriors from the north, their position being precisely analogous to that of the Manchou emperors in China. From the end of the 10th century the emperors of Constantinople had, till the fall of the city in 1453, a picked bodyguard of Varangians. The men of the north esteemed it a high honour to have served in this chosen cohort at Myklegård (i.e. 'the Great City'); and doubtless they carried back to their countrymen at home many elements or traits of the civilised refinement of the Byzantine court. After the Norman Conquest of England large numbers of English Northmen made their way to Constantinople and enlisted in the Varangian guard; these were the only men whose battle-axes cost Robert Guiscard and his Normans trouble at the great battle of Dyrrhachium (1082).

North Sea. The North Sea, or German Ocean, is a southern extension of the Arctic Ocean (q.v.). It communicates freely with that part of the Arctic Ocean lying between Iceland and Norway which has received the name of the Norwegian Sea. Its northern boundary would be represented by a line drawn from the Shetland Islands to the opposite coast of Norway, and its southern boundary is the

Strait of Dover; on the west it is bounded by the east coast of Great Britain, and on the east by the coasts of Norway, Denmark, Germany, Holland, and Belgium. With the North Atlantic Ocean it has communication through the Strait of Dover and the English Channel on the south, and on the north by the Pentland Firth and the channel between the Orkney and Shetland Islands; with the Arctic Ocean as already stated; and with the Baltic by the Skagerrack and Kattegat. The North Sea is over 600 miles in length and about 400 miles in greatest width, and its area is estimated at over 160,000 sq. m. By far the greater proportion of this area is less than 100 fathoms in depth, the only part where deeper water is found being off the coast of Norway (the Norwegian Gully or Norwegian Deep, as it has been called), where a depth of 360 fathoms has been recorded; the mean depth of the whole area is estimated at 61 fathoms. The sea is very shallow towards the south and east, and the coasts in this direction are low and flat, being in some places below the level of the sea, whereas to the north and west, where the water is deeper, the seacoast is high, and the deep Norwegian Gully is faced by the high and bold cliffs of Norway. The sea-bottom is very irregular, a number of banks running across from the Yorkshire coast towards the Skagerrack, the most important of which is the Dogger Bank (q.v.), and there are also depressions like the Silver Pit; off the low-lying coasts of Holland, Belgium, and Britain there are numerous shoals and sandbanks formed of the materials brought down by the rivers. The North Sea is surrounded by continental land and receives the waters of numerous rivers, the principal of which are the Thames, Ouse, Humber, Tyne, Tweed, Forth, and Tay, the Scheldt, Rhine, Weser, and Elbe. The deposits forming on the bottom consequently belong to the class called 'terrigenous,' consisting in the shallower water of sands and gravels and in the deeper water of muds and clays, containing stones and fragments of rocks and minerals derived from the land, along with calcareous fragments of shells and other organisms.

The salinity of the water of the North Sea varies between 1·025 and 1·027, the lightest water occurring in the southern part and in the Skagerrack, where fresh water comes from the Baltic, and the densest water at the bottom in the deep water off Norway. The mean temperature of the air over the North Sea in summer is about 60° F., and in winter about 36°, the range throughout the year being about 34°—from 31° to 65° F. Except in the summer months, the temperature of the surface water is higher than that of the air, the mean temperature of the surface water in summer being about 58°, and in winter about 42° F. The winds are variable over the North Sea, the most prevalent being from the south-west, and the currents are chiefly dependent on the direction of the wind; fogs, mists, and rain occur at all seasons. The great tidal wave of the Atlantic advancing from the west is divided into two portions on striking the British Islands: the one entering the North Sea round the Orkneys and through the Pentland Firth, the other coming up the English Channel.

The North Sea has been from the earliest times one of the most important highways of the world, and is surrounded by some of the most prosperous commercial nations, famous for their maritime exploits. The fisheries of the North Sea are among the most important in the world, providing employment for thousands of fishermen from the surrounding countries; all the varieties of food-fishes abound, as well as edible molluscs and crustaceans, such as oysters, mussels, lobsters, crabs, and

shrimps. The value of these fisheries depends to a great extent upon the abundance of the fauna and flora living on the sea-floor, all the various groups of invertebrates being met with in great profusion in the North Sea, while the surface waters swarm with algæ, such as diatoms, &c., which sometimes form extensive floating banks.

North Shields. See SHIELDS.

Northumberland, the most northerly county of England, separated from the Lowlands of Scotland by the Tweed and the Cheviots, and from the county of Durham by the Tyne and Derwent. The German Ocean bounds it on the E., and the county of Cumberland, with a part of Roxburghshire, on the W. Among the English counties it ranks fourth in regard to size, having an area of 1,291,515 acres. Its greatest length is 70 miles and its greatest breadth 47 miles. The surface of the county, except near the coast, is picturesquely broken into rounded and conical-shaped hills and high moorland ridges. The main valleys are fertile and well wooded. The principal heights belong to the Cheviot Hills (q.v.), and are seated in the north-west part of the county. These are Cheviot (2676 feet), Hedgehope (2348 feet), Cushtat Law (2020 feet), Bloody Bush Edge (2001 feet), and Windy Gyle (1963 feet). The Simonside Hills near Rothbury attain a height of 1447 feet. The chief rivers are the Tyne (formed by the confluence of two streams, the North and South Tyne, a little above Hexham), the Wansbeck, the Coquet, the Aln, the Breamish, the Till, and the Tweed. In the south-west of the county are some small sheets of water called the Northumbrian Lakes, the largest of which is Greenley Lough. Off the coast lie a few islands—Lindisfarne or Holy Island, the Farne Islands, and Coquet Isle. The geology of the county is simple in its broad features. The beds as a whole slope to the sea, the direction of the general dip lying between south-east and east; hence the oldest rocks—the Silurian—appear in the north-west, near the head of the Rede and Coquet, and the later formations—the Triassic and Permian beds and the coal-measures—near the coast. The strata have been dislocated and broken by volcanic disturbances, during which were intruded the igneous rocks. The Cheviots, which cover an area of 200 sq. m., owe their origin to the earlier of these upheavals. They consist chiefly of andesites and porphyrites. The Whin Sill, a great sheet of basalt stretching across the county from Kylee near Berwick to Greenhead in Cumberland in a series of columnar crags, was injected among the sedimentary rocks during the later eruptions which took place, it is supposed, at the close of the Carboniferous period. A number of basaltic dykes also cross the county. The coal-measures occupy the south-east part of the county, and the lead-measures (belonging to the Upper Limestone series or Yoredale rocks) the south-west.

The climate is cold, especially from March to the middle of June, when the prevailing winds are from the east and north-east. The winters, however, are often much milder than they are in the south. The average rainfall, too, except in the Cheviot district, is considerably less than in the counties of Devon, Dorset, Hampshire, and Sussex. Northumberland ecclesiastically is in the province of York. For the purposes of civil government the county is divided into nine wards (answering to hundreds or wapentakes), three of which formed part of Durham till 1844. It comprises three parliamentary divisions—Wansbeck, Hexham, and Berwick-upon-Tweed, returning three members. The principal towns are Alnwick, Morpeth, Hexham, and North Shields. Newcastle-upon-Tyne (q.v.) is a city and county of itself. A large portion

of the county is agricultural, especially the fertile tracts along the principal valleys and near the coast. Turnips grow well, the cultivation of them on raised ridges being peculiar to the county, and known as the Northumbrian system. The western portion of the county is pastoral, the slopes of the Cheviots affording sustenance to large flocks of hardy sheep. In Chillingham Park there is preserved a herd of so-called wild cattle. The trade of the county in coal is very great and the chief manufactures are connected with its mining and transit. There is also a large output of iron ore, barium, lead, and fire-clay. The collieries are chiefly in the south-eastern part of the county. In shipbuilding the Tyne is surpassed only by the Clyde. The salmon-fisheries of the Tyne and Tweed have long been famous. The county is traversed by the London and North-Eastern railway. Pop. (1801) 168,078; (1841) 266,020; (1891) 506,030; (1921) 746,138.

Northumberland in the time of the Romans was inhabited by a branch of the Celtic people, the tribe of the Ottadini. In the 6th century it was conquered and colonised by the Angles. It then formed part of the kingdom of Bernicia. Being a border county, it suffered much during the Scottish wars, and from the 11th to the 17th century was frequently the scene of much bloodshed. The battles of Otterburn, Homildon Hill, and Flodden were fought on its soil. Northumberland is very rich in memorials of the past. No county, indeed, has a more interesting collection of military antiquities, from the rude circular camps and entrenchments of the old inhabitants to the great castles and peel-towers of mediæval times. The Romans have left a mighty monument of their power in the great barrier erected across the southern portion of the county, and in the stations and roads connected with it. Other antiquities, also noticed separately, are at Bamburgh, Dunstanburgh, Hexham, Alnwick, Holy Island, Norham, &c. Northumberland is the birthplace of Bishop Ridley, Thomas Bewick, Akenside, Lord Eldon, George and Robert Stephenson, Grace Darling, the second Earl Grey, Birkett Foster, and Lord Armstrong.

Works treating on the history, antiquities, geology, &c. of the county are: the *Histories of Wallis* (1769), *Hutchinson* (1778), *Mackenzie* (1825), and *Hodgson* (1820-40); *Hodgson* *Hinde's General History of Northumberland*, an addition to Hodgson's great work (1858); *Bateson and others, History of Northumberland* (12 vols. 1893 et seq.); *Mawer, Placenames of Northumberland and Durham* (1920); *Hartshorne, Feudal and Military Antiquities of Northumberland* (1858); *Gibson, Northumbrian Castles, Churches, and Antiquities* (1848-54); the *Proceedings of the Newcastle Antiquaries*, and the *Surtees Soc.*

Northumbria, the most northern of the ancient English kingdoms, stretching from the Humber northwards to the Firth of Forth, and separated westwards from Cumbria and Strathclyde by the Pennine range and the Ettrick Forest. Bernicia, the district north of the Tees, had for its first king Ida (547-559), who built Bamburgh as his capital. His grandson, Ethelfrith, mounted the throne in 593, and having married the daughter of Ella, who in 560 had formed the kingdom of Deira out of the district between the Tees and the Humber, set aside the rights of his boy brother-in-law Edwin, and so united both Bernicia and Deira into one kingdom. But the ousted Edwin, returning to defeat and slay the usurper in 617, thereupon himself became king of the Northumbrians as well as Bretwalda. Under him Northumbria was Christianised. In 633 he fell in battle against Penda of Mercia and the Welsh Cadwallon, but a year later St Oswald, son of Ethelfrith, cleared the country of the invaders, and united both divisions

under his rule. His brother and successor, Oswy, was forced to yield Deira to Oswin, son of Osric, his cousin, but in 654, by a great victory in which Penda perished, was able anew to unite his kingdom, and reigned till 670 the most powerful of all Northumbrian kings. Under later kings—Egfrid (670–685), Aldfrid (685–705), a great patron of learning, and as many as fourteen obscure successors, most of whom came to a violent end—Northumbrian influence gave way before the rise of Mercia, internal tumults, and Danish ravages, until 806, when the chroniclers cease to give a regular succession of kings, and 827, when Northumbria became tributary to Egbert. See the *Histories of Green, Skene, Freeman, and Hodgkin*.

North-west Frontier Province, a new province of India to the north-west of the Punjab, constituted in 1901 under a chief commissioner, and comprising the districts of Hazara, Peshawar, Kohat, and parts of Bannu and Dera Ismail Khan, heretofore in the Punjab. Attached are five political agencies—viz. the Khyber, Kurram, Tochi, and Wana agencies removed from the Punjab and the Malakand agency. The deputy commissioners of the five districts are also responsible for the political relations of certain trans-border tribes. Area districts, 13,418 sq. m.; agencies and tribal areas, 25,500 sq. m.; population (1921), districts 2,251,000; agencies, &c., 2,825,000.

See Wyllie, *From the Black Mountain to Waziristan*.

North-west Passage, a route for ships from the Atlantic to the Pacific by the north of America. The *North-east Passage* is that by the north of Asia. See *POLAR EXPLORATION, ARCTIC OCEAN, FRANKLIN (SIR JOHN)*.

North-west Territories of Canada. The area originally known as the North-west Territories has been altered by the separation therefrom of the provinces of Saskatchewan and Alberta, parts of Manitoba, Ontario, and Quebec, and the addition of territories and islands previously known by other names. In 1905 acts were passed by the parliament of Canada establishing the provinces of Saskatchewan and Alberta, and declaring that 'the North-west Territories shall hereafter comprise the territories formerly known as Rupert's Land and North-western Territory, except such portions thereof as form the provinces of Manitoba, Saskatchewan, and Alberta, the district of Keewatin and the Yukon Territory, together with all British territories and possessions in North America, and all islands adjacent to any such territories or possessions except the colony of Newfoundland and its dependencies.' In the same year Keewatin was brought under the provisions of the North-west Territories Act. The extent of the North-west Territories after the expansion in 1912 of Manitoba, Ontario, and Quebec was reduced practically to the district 'between Hudson Bay and the Yukon, and is estimated at 1,242,000 sq. m. The Territories are divided into three provisional districts, Franklin, Keewatin, and Mackenzie, and are administered by a commissioner and a council of four appointed members, who are invested with authority to make ordinances and appointments within specific limitations, under instructions from time to time given by the governor in council or the Minister of the Interior.

The resources of the Territories are game, great numbers of musk-ox, fish, timber, water-power, minerals, the oilfields covering large areas; explorers, prospectors, and representatives of capitalists are giving much attention to various sections, and it is not unlikely that within the next generation the new North-west of Canada will supply the world with surprises quite equal to the

wheat production of the old North-west. The native population of the North-west Territories is composed of Indians and Eskimo—all of whom have given unmistakable evidence of a desire to meet the white man in the most friendly spirit, and adapt themselves to the laws and methods of civilisation. Pop. 8000.

Northwich, a market-town of Cheshire, on the river Weaver and the old Watling Street, 18 miles NE. of Chester. Known to the Romans as *Salinæ*, it has long been the centre of the salt-industry, both rock and white salt being largely exported. The town possesses brine-baths having considerable curative properties. The parish church of St Helen has a finely carved 16th-century roof, while there is also a well-equipped library and museum. The town was the scene of much heavy fighting during the Civil War. Pop. 18,000.

Norton, ANDREWS, born at Hingham, Massachusetts, 31st December 1786, graduated at Harvard and became professor there of biblical criticism and interpretation. One of the most distinguished exponents of Unitarianism, he also keenly opposed Theodore Parker and the naturalistic theology. His chief writings are *Reasons for not believing the Doctrines of Trinitarians* (1833), and two works on *The Genuineness of the Gospels*. He died at Newport, Rhode Island, 18th September 1853, leaving also a translation of the gospels, which was edited (1855) by Dr Ezra Abbot and his son, CHARLES ELIOT NORTON, who was born at Cambridge, Massachusetts, 16th November 1827, and graduated at Harvard in 1846. He travelled in India and Europe, was joint editor with Lowell of the *North American Review*, wrote on Italy, and edited Carlyle's letters and Ruskin's letters to himself (1904). He died on the 21st October 1908.

Norton, THE HON. MRS. Caroline Sheridan, poet and novelist, was born in 1808, the second of the three beautiful granddaughters of Richard Brinsley Sheridan. One of her sisters became Lady Dufferin, the other Duchess of Somerset; and she herself in 1827 married the Hon. George Chapple Norton (1800–75). She bore him three sons, of whom Thomas Brinsley (1831–77), the second, succeeded to the title of fourth Lord Grantley; but the marriage proved a most unhappy one, and her friendship with Lord Melbourne (q.v.), whom she first met in 1831, led her husband to institute five years afterwards a groundless and unsuccessful action of divorce, the damages laid at £10,000. Already she had made by her pen £1400 in one year, and after the separation from her husband she continued her literary activity. Her poems include *The Sorrows of Rosalie* (1829), *The Undying One* (the Wandering Jew, 1830), *The Child of the Islands* (1845), and *The Lady of La Garaye* (1862); her novels, *Stuart of Dunleath* (1847), *Lost and Saved* (1863), and *Old Sir Douglas* (1868). In March 1877 she married Sir William Stirling-Maxwell (see MAXWELL, SIR W. STIRLING-), but died on the 15th June following. An exploded story about her supplied the subject for George Meredith's *Diana of the Crossways*. See *Life by Miss Perkins* (1909).

Norwalk, (1) a city of Connecticut, at the mouth of a river of the same name, on Long Island Sound, 41 miles by rail NE. of New York. It has a good harbour, extensive oyster-fisheries, large manufactories of straw-hats, felt-hats, and cloth, woollens, shirts, shoes, tires, locks, and door-knobs, besides foundries and ironworks. Several of these establishments are in South Norwalk, which was formerly a separate city. Pop. of Norwalk 28,000.—(2) Capital of Huron county, Ohio, 55 miles by rail WSW. of Cleveland. It is a pleasant little town, with streets shaded with

maples; manufactures organs, shoes, ploughs, sewing-machines, tobacco. It has steel and iron-works, and ships small fruits. Pop. 7400.

Norway (Norweg. *Norge*), the western division of the Scandinavian peninsula, extends (without reckoning Spitsbergen) from lat. 57° 59' N. (Lindesnæs) in the south-west to 71° 11' in the north-east, overlapping Sweden and Finland on the N. and screening them from the Arctic Ocean. Although 1160 miles in length (coast-line 3000 miles), it varies in width from 20 to 100 miles north of 63° N. lat.; below that line it swells out to a club-shaped mass 260 miles in width. It is separated from Sweden by the Kjölen (i.e. Keel) Mountains (3000 to 6000 feet), the backbone of the peninsula, which run parallel to the Norwegian coast from the plateau of Finmark in the north to 63° in the south, and then bifurcate. The main range proceeds southwards, still marking the boundary between the sister kingdoms, though it decreases greatly in height. The other division continues parallel to the coast, in a south-westerly and then southerly direction, to the extremity of the country. But the mountains in this division no longer form a narrow ridge or 'keel'; they widen out into a broad plateau, undulating between 2000 and 4000 feet and embossed with mountain-knots—Dovre, Jotun, Lang, Fille, Hardanger Fjelde (*fells*)—the separate peaks of which shoot up to 6000 feet and higher (e.g. Galdhöppigen, 8399 feet; Glittertind, 8379; Snehetten, 7566; Lodalskaupen, 6790 feet). The leveller portions of this plateau region consist of dreary moors, covered in winter with snow and in summer with coarse grass and heather, and studded with numerous tarns and belts of forest (conifers, birches, willows). The grass affords pasturage to the sheep and cattle of the dalesmen; the *sætre* or huts of the herd-girls and the wood-cutters are the only habitations in these mountain solitudes. But the bear, lynx, wild reindeer, and lemming make their home there; owls, kestrels, and buzzards prey on the smaller animals and birds; snipe, teal, and loom frequent the lakes; and vast numbers of lapwing and plover breed in the tarns. Moreover, in winter the ptarmigan is plentiful on the snows. Besides these creatures, the fox, eagle, sparrow-hawk, raven, crow, and woodcock are common, not only here, but throughout the kingdom. Numerous wild berries—cloudberry, raspberries, bilberries, cranberries, &c.—ripen on these loftier regions in summer.

Norway presents a bold front to the Atlantic. The west side of the peninsular rampart—the 'Westland,' which is nowhere more than 70 miles wide—sinks down abruptly to the ocean, in some cases by steep terraces, in others sheer to the water's edge. On the inner or eastern side—the 'Eastland'—the slope is more gradual; the general versant faces south-east. The greater part of the country lies between the same degrees of latitude as Greenland, and would in all probability be covered with a similar ice-cap to Greenland—as indeed it was in the end of the Tertiary period—were its shores, on west and north, not washed by the Gulf Stream. It is mainly owing to this warm oceanic artery that Norway is habitable; its influence, together with the direction of the parallel mountain rampart, the distribution of the atmospheric pressure, and the presence of deep-sea banks off the coast, determines the predominant climatological features of the country. The isotherms do not run from west to east, but parallel to the coast. Hammerfest, for instance, on the north coast, in 70° 40' N. lat., has a winter mean of 22·6° F., 3° higher than Oslo, which has virtually an inland site, in 59° 55' N. lat. In winter the west coast districts are the warmest, and the cold increases in intensity

according to the distance inland; whereas in summer the reverse is the case, though altitude is then a more potent influencing factor than in winter. The places that have the lowest winter mean (11·8°) are all inland, as Elverum and Røros (Røraas), near the Swedish frontier, Kautokeino (in southern Finmark), and Nyborg (at the head of Varanger Fjord); at all these places the mercury has been known to freeze (−40° F.). The places which have the highest summer temperature are Oslo, the south-west extremity of the country, the heads of the western fjords, and the interior of Finmark. The prevalent south-west winds bring considerable rainfall, 40 to 70 inches in the year, to the west coast of southern Norway. In the interior only 12 to 16 inches fall during the year.

The population has much more than doubled since 1820, when it stood at 977,500. In 1885 there were only nine towns with populations exceeding 10,000; in 1920 there were eighteen—Oslo (Kristiania), the capital (258,483), Bergen (91,443), Trondhjem (55,030), Stavanger, Drammen, Hauge-sund, Ålesund, Kristiansand, Skien, Fredrikstad, Kristiansund, Tønsberg, Larvik, Fredrikshald, Sarpsborg, Horten, Arendal, and Tromsø—all seaport towns. The density of the population over the entire surface is 21·2 per square mile, much the lowest of any country in Europe except Iceland; but then fully 70 per cent. of the total area is wholly uncultivable, being barren mountain and waste (2 per cent. under glaciers); in addition about a fifth is forest. In 1891 the population was 1,999,176; in 1920 2,649,775. Details as to area and population are given below.

COUNTIES (<i>Fylker</i>).	Area, English sq. m.	Census Population, 1st Dec. 1920.
Oslo (town).....	6·3	258,483
Akershus.....	2,068·9	179,962
Østfold.....	1,614·1	160,128

Total.....	124,964·3	2,649,775

To these must be added Svalbard (Spitsbergen and Bear Island), now an integral part of Norway: area, 25,000 sq. m.; pop. about 1500 in summer, 1000 in winter. Jan Mayen (150 sq. m.; uninhabited) has been annexed. For map, see SWEDEN.

The vast majority of the Norwegians are of Nordic race, Scandinavian in tongue. There were besides in 1920 (apart from foreigners) 7309 Finns (called Kvæns by the Norwegians), 19,329 settled and 2814 nomad Lapps (called Finns).

Finmark, which is inhabited in great part by Lapps, is a monotonous undulating plateau (1000 to 2000 feet). The coast is deeply indented with large fjords (Varanger, Tana, Laxe, Porsanger, Alten), and east of the North Cape (q.v.) is low, bare, and bleak, though the banks of Pasvig, the frontier river with Finnish Lapland, are green with patches of fir, pines, and birches. Vegetables, barley, and peas ripen on the shores of the fjords, thanks to the Gulf Stream and the eight weeks' uninterrupted sunlight that prevails in summer. At that

season too gnats are a terrible plague to man and beast. The cliffs and islands swarm with wild-fowl, and the sea-waters with fish. The wolf and glutton are common, the former being a dangerous enemy to the Lapps' reindeer herds. West of 22° E. long. the coast breaks rocky, wild, and precipitous, its outline being irregular in the extreme; and these characteristics it preserves right down to below 59° N. lat., to the point nearest Scotland (280 miles distant). From this point up to the North Cape the entire coast is protected from the Atlantic waves by a belt of rocky islands, called the Skjærgaard or 'Skerry Fence,' between which and the coast there are connected navigable roads, sheltered and safe at nearly all seasons. The outermost islands of this belt are the Lofoten and Vesteraalen chains; in both groups the mountains (2000 to 3000 feet) rise in extremely fantastic pinnacles and turrets, with razor-backed saddles and gabled roofs. But wherever, on these and all the other islands of the Skjærgaard, there are level patches and ledges of soil touched by the modifying climatic influences grass grows abundantly. The climate of the Lofoten is indeed so mild that rye and barley easily ripen, and large flocks of sheep are left out all winter, whilst many thousands of fishermen congregate here in the winter to prosecute the herring and cod fisheries. All the islands of the Skjærgaard are frequented by enormous quantities of sea-birds, chiefly of the duck and gull varieties; they are 'fowled' for the sake of their down (from the eider duck), feathers, flesh, and oil. On some of the islands the red deer still lingers. On the mainland the mountains in the north have the same bare, angular outlines as in the Lofoten, but support in many parts large forests of fir and pine; in southern Norway they have rounded, dome-shaped summits, and are, next the sea, only sparsely covered with fir (no pine) and other trees. The peninsular rampart is crowned with several gigantic glaciers—e.g. the shores (6000 feet) of Lyngen Fjord in the north are lined with them; from Jökul Fjeld, on an arm of Kvenang Fjord, large masses of ice drop off the glaciers into the sea and float away as icebergs; just north of 67° N. lat. is the enormous snowfield of Sulitjelma (6168 feet), and just south of the same parallel Svartisen (3600 feet), the second largest glacier in Norway, measuring 44 miles by 12 to 25, and sending down glacier curtains to within a few hundred feet of the sea; south Norway possesses the second largest glacier in Europe (Vatnajökull in Iceland being the largest), the roof-shaped Justedal (4600 to 5400 feet), which has an area of 580 sq. m. (87 miles long by 6 to 22 miles wide), and reaches down its icy polypous arms to within 150 feet of the sea; to the south of it lies the snowfield of Folgefond, 40 miles long and 7 to 15 wide (108 sq. m.), and 3000 to 5000 feet in altitude. Throughout Norway the limit of perpetual snow ranges from 2300 feet on Justedal to 5150 on the Dovre Fjeld.

The lofty west coast region is everywhere cleft by gigantic fissures, very narrow and winding, into which the sea-water flows—the fjords. In some cases they are of great depth, much deeper than the sea outside (200 fathoms): Sogne Fjord, for instance, is 2820 feet deeper; Hardanger Fjord, 930 feet; and Vest and Nord Fjords, 840 feet. Some of them penetrate great distances inland and send off numerous branching arms. Sogne Fjord cuts its way to the foot of the Jotun Fjeld, 106 miles from the ocean, and Hardanger Fjord, which encircles the Folgefond, is 68 miles long. Nord and Sogne Fjords clasp the Justedal between them. These three fjords offer some of the grandest and most accessible scenery in Norway. Their landward continuations either rise rapidly to the plateau region

above or form narrow valleys at a slightly higher elevation, and in that case generally contain a deep lake separated from the fjord by a moraine or barrier of glacial deposits. The finest of these valleys is Romsdal, where the rounded, pure gneiss mountains tower up to 6000 feet with almost perpendicular walls. The steep sides and extremities (2000 to 4000 feet) of these fjords and valleys are braided with waterfalls, varying in character from trickling ribbons and veils of white foam to full-volumed streams like Skjæggedal (530 feet), Vöring (475 feet), and Vetti (900 feet). The inner reaches of the fjords have as a rule warm summers and mild winters; all the ordinary cereals and hardy fruits ripen easily, and such trees as fir, birch, hazel, elm, mountain ash, aspen, bird-cherry, oak, ash, lime, and alder grow according to the elevation. The only considerable break in the lofty coast-wall is the basin of Trondhjem, a little north of 63° N. lat. This district was the centre of the ancient national life of the country, and in the cathedral of Trondhjem city (called Nidaros to the middle of the 16th century) the kings of Norway are still crowned. The southern coast-lands, bordering the Skagerrack and the wide Christiania Fjord, are comparatively low and tame.

On the eastern side of the peninsular rampart the valleys trend south and south-east, and converge upon Christiania Fjord. At their upper extremities they are generally narrow and deep; and many are filled with chains of lakes, and make fine waterfalls (Rjukan, 800 feet, in Telemark) as they drop from level to level; their lower reaches get wider and shallower as they proceed south. Most of these valleys are traversed by mountain torrents and streams, the longest being the Glommen (350 miles), Drammen (163), with its tributary the Hallingdal (113), Nummedal Laagen (143), and Otteren (140). Some of these streams in their lower courses expand into long narrow lakes of considerable size: Lake Mjösen is 60 miles long, and its bottom is 1080 feet below the level of the sea; others are Randsfjord (43 miles long), Tyrifjord (19 miles), and Fæmund (35 miles long and 2300 feet above sea-level). The slopes of these valleys, especially in the southern and eastern parts of the country, are planted for miles upon miles with forests, chiefly fir. In these forest regions the elk is still found, and the blackcock, capercaillie, and hazel-grouse abound. The trees are felled principally in winter, and floated down the streams in early spring to the sawmills at their mouths.

Geology.—The great mass of the Norwegian plateau consists almost entirely of Archaean rocks, chiefly granite and gneiss, with quartz and hornblende schists in a subordinate degree, in very many cases clearly stratified. In central and western Norway (the fjeld region) the primary rocks are covered with layers of metamorphosed clay-slate and quartzite, whilst large masses of eruptive rocks of later date, such as granite, syenite, gabbro (especially in the Jotun Fjeld), porphyry, greenstone, labradorite, serpentine, have pierced through both formations and overspread them in broad sheets or coverlets. The prevailing formation in eastern Norway is called Sparagmite, a loose accretion of conglomerates and breccias, sandstone and quartz. Bands of Silurian rocks extend across the southern part of the country from south-west to north-east, the two most clearly-defined belts stretching from Hardanger Fjord to Trondhjem and from Skien Fjord (on the south coast) to Lake Mjösen. Most of the rocks of the plateau have been greatly crumpled, folded, twisted, crushed, and dislocated. The prevailing formation throughout northern Norway is granite. Nearly all parts of the country bear conspicuous traces of the scratch-

ing, grinding, and polishing to which the structural rocks were subjected during the Glacial age and the period of its departure. Incised and striated lines, and polished surfaces, occur at all altitudes up to 5000 feet, and generally follow directions radiating outwards from the highest mountain-knots of the peninsular rampart. Boulders litter the surface of the country nearly everywhere; moraines are numerous, and transverse ridges of glacial detritus block the mouths of many of the valleys; 'giant kettles,' the basins that received the glacial cataracts, occur in numerous districts near the sea. Moreover, the lines of ancient beaches, whether of the ocean or of glacial lakes, are distinctly traceable at many points along the coast from Bergen to the North Cape; sometimes there are two, or even more, one above another. The coast of northern Norway is estimated by some authorities to have risen between 400 and 600 feet. See UPHEAVAL.

Industries and Occupations.—Norway's economic wealth lies in her fisheries, in her forests, in her water-power and resultant manufactures, and in her shipping; her mines and her agriculture are unable to meet the home demands.

By far the most important of the fisheries are the cod and herring. Cod are taken on the west coast from January to April. They are cured chiefly in two ways, being either dried on wooden frames (hence called *tørfisk*, 'dry fish') or slightly salted, carried to the mainland, split open, and dried on the rocks (hence called *klippfisk*, 'split fish'). The former are exported to Italy, the latter to Spain. Cod-liver oil and salted roe rank high among the country's exports, and heads and offals, powdered for manure, are also exported. Herrings are taken all the year round. Mackerel and oysters are taken off the south coast, and salmon and sea-trout and lobsters off the west coast and elsewhere. Off the north coast of Finmark cod, saithe, flounders, smelt, &c., are taken in summer. The fishery in the Polar seas for whales, walrus, seals, dog-fish, sharks, &c., is prosecuted from Tromsø, Hammerfest, and Vardø. The inland lakes and rivers contain an abundance of salmon, trout, and red charr, and some of the southern lakes have also grayling, bream, perch, and pike.

The forests cover about 22 per cent. of the entire surface, though the area was formerly very much greater. Trees are, however, being systematically planted in several parts. The sawmills give employment to thousands of men, whilst many are engaged in the preparation of wood-pulp and cellulose.

Agriculture is carried on chiefly near Oslo, at the lower ends of the eastland valleys, in the level district of Jæderen in the extreme south-west, and around Trondhjem. The farms are mostly small (under 2 hectares). The rearing of cattle, sheep, and goats—in the north reindeer—is important. The area under cultivation is only about 3·4 per cent. of the entire surface of the country.

Copper and iron pyrites, silver, aluminium, and zinc are produced. Lack of coal and abundance of water-power and of timber determine the manufactures: electro-chemical and electro-metallurgical products, wooden goods, wood-pulp, paper, matches, &c. Shipbuilding is carried on, chiefly in the south.

The Norwegians rank amongst the busiest sea-carriers of the world. The largest items of import are textiles, articles of food (cereals, groceries, and fruits), metals (unwrought and manufactured), machinery and ships, coal, yarn and rope, tallow and oils, hides and skins. Timber and manufactures of timber, fishery and other animal products, form two-thirds of the entire exports. Much

of the timber is exported as deals and boards, the remainder being manufactured, and of this wood-pulp forms a large proportion. The animal products are principally fish and fish produce, but include also cattle, butter, and preserved milk. The other principal exports are paper and paper manufactures, skins and tallow, metals and metal-ware. Great Britain and Ireland and Germany have about half of the Norwegian trade between them. The chief exports to Britain are wood and wood-pulp, fish, and matches; the chief imports from Britain are coal, iron and steel, cotton, and ships. The principal ports are Oslo, Bergen, Trondhjem, Frederikstad, and Drammen.

People.—The Norwegians are among the most democratic peoples in Europe. They are proud of their freedom and independence, are simple, honest, and straightforward, frugal, and in general unaffectedly pious, though in some districts liable to violent outbursts of passion. Otherwise they are slow of action and take life leisurely. Formerly intemperance was a vice, but from 1871 the reform of the licensing system was undertaken (see LIQUOR LAWS). The rural population are decidedly more democratic than the urban. All titles of nobility were abolished in 1821, and none but townfolk use the equivalent of our 'Mr.' Owing to the insufficiency of the natural resources of the country to support the people considerable number emigrate, almost all going to the United States. Those who remain behind are fairly prosperous on the whole. Their difficult country has compelled the Norwegians to perform some feats of engineering skill of no mean order. As road-makers they vie with the Swiss. But the principal means of communication are steamboats, which ply all along the coast, on the fjords, and the inland lakes. There are, however, some 20,000 miles of well-kept national and communal roads, and some 2200 miles of railway (all but 270 miles managed by the state). Electrification of the railways is in progress. The lines radiate chiefly from Oslo. Two connect Trondhjem with the capital, and since 1891 four separate railways connect Norway with Sweden. Norway is now visited every summer by great numbers of tourists, especially from Britain, the rest chiefly Swedes, Danes, and Germans.

The people are on the whole well educated and intelligent. Attendance at school is free, and compulsory upon all children between seven (six and a half in towns) and fourteen. The country is well equipped with primary schools, and for the higher branches there are over 100 secondary schools (public, communal, and private), and the university of Oslo, with 1400 students. Trondhjem has a technical high school; Aas an agricultural high school. The state contributes about one-fourth of the total cost of the public education. The state religion is the Evangelical Lutheran. The dissenters (Methodists, Baptists, Roman Catholics, &c.) number only 71,000. For purposes of ecclesiastical government the country is divided into seven dioceses (*stifts*), each administered by a bishop—viz. Oslo, Hamar, Kristiansand, Bergen, Trondhjem, Tromsø, and Stavanger.

Constitution.—Even during the union with Sweden (1814-1905) Norway was not merely a free state and nation, but in many respects was essentially a republic; and the union of democratic—almost republican—Norway with aristocratic Sweden never worked smoothly. The nationalist movement became pronounced in 1890. An agitation for an even larger measure of home rule, and diplomatic representation distinct from that of Sweden, ended in the refusal by Sweden to grant the concessions asked and in the formal proposal by Norway, in 1905, to withdraw from the union with Sweden. After some negotiations

and the meetings of Swedish and Norwegian parliaments a separation was amicably agreed to, and in October the union was cancelled, and Norway was again an entirely distinct and independent state. Prince Carl, second son of the Crown-prince of Denmark, was chosen king, as Haakon VII. The supreme executive rests with the king; but the responsibility for his acts is borne by a council of state. The Storting or parliament consists of 150 members, 100 for country districts and 50 for towns. All Norwegians (male and female) above twenty-three years of age who reside and have resided in the country for five years are qualified as electors. The members, elected every three years, must be at least thirty years of age, have resided in Norway for ten years, and (except former ministers) be voters in the districts they represent. As soon as the Storting meets (in January every year in Oslo) one-fourth of the assembled members are chosen to form an upper house (*Lagting*); the remainder constitute the lower house (*Ödelsting*), in which all legislative measures are proposed either by a member of the house or by a member of the government. The upper house may pass or reject a bill; in case of disagreement the houses vote together as one, though in that case a majority of two-thirds is necessary. If a bill is passed by three successive parliaments (not sessions), it becomes law in spite of the king's veto. Nearly all offices were thrown open to women in 1912, the cabinet in 1916. Both the counties and the communes enjoy a liberal degree of self-government. The monetary unit is the *krona* (=1s. 1½d.), divided into 100 *öre*. The metric system of weights and measures prevails. The national defences embrace an army and navy. Service in the army is compulsory and universal—12 years with the *Linje*, 12 with the *Landvärn* (Landwehr); men of the ages of 18 to 20 and 44 to 55 belong to the *Landstorm*. The navy consists of a permanent establishment reinforced by a quota of conscripts chosen annually from an active navy roll of all seafaring men between the ages of 20 and 44.

See Kier, *Norges Land og Folk* (1886); Kirchhoff, *Länderkunde* (pt. ii. 1890). In English, Du Chaillu, *Land of the Midnight Sun* (2 vols. 1881); F. Vincent, *Norsk, Lapp, and Finn* (1881); Mary Godwin, *Letters from Norway* (1796); J. D. Forbes, *Norway and its Glaciers* (1853); Daniels, *Home Life in Norway* (1911); Burchardt, *Norwegian Life and Literature* (1920); Gathorne Hardy, *Norway* (1925); *The Norway Year Book* (ed. Hammer). The best guide-books to the country are those by Yngvar Nielsen, Baedeker, Tönsberg, Bennett, Jørgensen, and Willson.

History.—It is not until the 9th century that the story of Norway begins to emerge from the obscurities of myth and legend. When the tribes of Gothic descent crossed the Baltic and settled in the southern parts of the Scandinavian peninsula they found a race, perhaps Finnish, in possession. These people they drove north towards the Arctic Ocean. When this immigration took place cannot be determined exactly. Indeed, if, according to one theory, the original home of the Aryans was in Scandinavia, it probably never took place at all. At the dawn of the historical period Norway was parcelled out among the free men of the race (Norreni, Norsemen, Norwegians), whose slaves—prisoners taken in war—tilled the soil, whilst they and their free dependents spent their time in fighting, viking raids, and similar pursuits. The ties that united these free men were personal rather than political or territorial, though for judicial purposes all who dwelt in a well-defined district (*fylki*) met at stated intervals and at fixed places to adjudicate in common, on terms of strict

equality. Several of these districts were associated together in a higher unity—the *thing*. Of such *things* or meetings there came to be eventually three, the Frosta for the north, the Gula for the west and south, and the Eidsfja for the east; at a later date the Borgar *thing* for the south-east was separated from the Eidsfja. Each of these *things* had its own independent code of purely customary laws. The chief men, calling themselves kings, later jarls (earls), had no official authority; their power was due solely to their personal influence—their character, wealth, warlike renown, and long descent (compare NORTHMEN).

The cradle of the future kingdom of Norway was the district of Vestfold, on the western side of Vik (now Christiania Fjord). There a royal race from Sweden established themselves, seemingly in the 7th century. A descendant of these kings, Black Halfdan (died 860), reduced the petty kings to the north of him, as far as Lake Mjösen. His greater son, Harold Haarfager or Fairhair (king 863–930), extended his sway as far north as Trondhjem, in which district, as being his first conquest in lands that owed no allegiance to the chief king in Sweden, he established the seat of his power, just as the elector of Brandenburg called himself Frederick I. king of Prussia. After that in three great sea-fights, the last near Stavanger in 883, he conquered the kings of the west and south-west, and proclaimed himself chief king in Norway. But many of the defeated chiefs (kings) refused to submit to Harold, especially when he asserted the right of conquest, seized their odal lands, and introduced a form of feudalism. They sailed across the Western (North) Sea, and colonised the Faroe, Shetland, and Orkney Islands, the Hebrides, Man, Ireland. But they so harassed the men (jarls) to whom Harold had given their lands in Norway that the king, pursuing them, slew many of them and reduced the islands to his sway, and appointed earls over them (Orkneys, Hebrides). Those who were still disaffected escaped his rule by sailing on farther to Iceland. In Harold's reign the skalds or improvisatore court-poets began to compose, and were held in great honour. Harold's son, Erik Blood-axe, was driven from Norway by a younger brother Haakon in 935, and for many years the country was distracted by Erik's sons trying to recover their father's power. After Haakon died (961) their principal opponent was Earl Haakon of Trondhjem, who ruled Norway west of the mountain plateau until he was killed in a revolt (995). Olaf Trygvesson, a descendant of Harold Haarfager, a man who had won great fame as a viking in England (991–994) and elsewhere, stepped into the gap. Like his great-uncle Haakon he was a Christian, and like him he attempted to make his people Christian, and he did make them Christian, at least nominally and superficially. The beau-ideal of a sea-king, and the pride and admiration of his people, Olaf died a hero's death, fighting against a host off the north coast of Prussia (1000). After an interval of fifteen years another Olaf, likewise a descendant of Harold Haarfager, landed and won the kingdom from the sons of Earl Haakon. This Olaf—St Olaf—made his people's Christianity more real, first thoroughly welded the kingdom into a united state, made all the western islands tributary, and ruled sternly but well. Ever since the days of Harold Haarfager the king of the Danes had claimed supremacy over at least southern Norway; in 1028 the great Cnut came with a large fleet to make good his claim. Olaf fled to Russia, and in attempting to win back his crown perished in battle at Stikklestad near Trondhjem (1030). Five years later the chiefs of the land made Olaf's son Magnus king, and he became king of the Danes also in 1042. But this office he found

so difficult that in 1046 he associated with himself as king his uncle Harold Haardraada, who had served in the Væring guard at Constantinople and had fought against the Saracens in Sicily. War between the Danes and Norsemen was almost chronic all through the reigns of Magnus and Harold, who became sole king in 1047. Harold's love of adventure led him to his death at Stamford Bridge in England in 1066. During the peaceful reign of Harold's son, Olaf Kyrre (1067-93), commerce thrived, industrial guilds were formed, and the land prospered greatly. The next king, Olaf's son, Magnus Barefoot, waged war in the Orkneys, Hebrides, and Ireland, till he fell in this last island in 1103. Two sons of Magnus, Eystein (died 1122) and Sigurd (died 1130), then reigned in concert, Eystein being a quiet stay-at-home prince, whilst Sigurd, who had inherited all the adventurous enterprise of his ancestors, sailed to the Levant, and visited Jerusalem and Constantinople (1107-11). After his return he greatly fostered the church. At this period the towns began to be prosperous.

From 1130 to 1240 the country was torn by internal feuds, three predominant parties contesting for power—an oligarchical party amongst the chief men; the bishops' party, who claimed the right to elect the king; and after 1174 the nationalist Birkebeiner (i.e. 'Birch-legs'), who generally had the first two parties allied against them, but who in the long-run got the victory. After defeating the earls and bishops, and slaying their nominee or puppet, King Magnus, in Nord Fjord (1184), they made their leader Sverre (died 1202, a Faeroe islander, and a clever man, king. Nevertheless, the civil strife went on until the twenty-third year (1240) of the reign of Sverre's grandson Haakon. This king reigned twenty-three years longer, and during that time the land recovered from her distractions. In 1262, Iceland acknowledged the supremacy of the king. Haakon died at Kirkwall (1263), shortly after being defeated at Largs in an attack upon Scotland. It was during the first half of the 13th century that the Old Norse literature began to be written down. The laws were put in writing during the reign of Haskon's son, Magnus the Law-betterer (1263-80), who, in 1266, gave up the Hebrides to Scotland. The pretensions of the bishops' party were finally crushed by Erik (died 1299), son of Magnus, and father of the little Margaret, Maid of Norway. Erik's successor, his brother Haakon, dying (1319) without a son, the throne passed through a daughter to the Swedish royal house, and again through marriage to the Danish (1380). The great Queen Margaret of Denmark united all three kingdoms by the Union of Kalmar (1397). And now evil days fell upon the land. The extraordinary exertions of Norway's youth seem to have worn her out early; her high spirit and enterprise were gone; her literature died out, and her intelligence burned down to a dull glimmer; her commerce passed into the tyrannical hands of the Hanseatic merchants of Bergen; her old colonies, Orkney and Shetland, were pledged to Scotland for ever in 1468; Denmark, which at first respected her national rights, treated her from 1536 as a conquered province, and forced the Reformation upon her, yet the Norwegians never seriously resented the harsh and oppressive treatment of their rulers. In 1612 some 300 men from Scotland, whilst making their way to join the army of Gustavus Adolphus in Sweden, were cut to pieces by the Norwegian peasantry in the pass of Kringelen in Gudbrandsdal.

The national spirit began to stir again in the awakening of the peoples occasioned by the French Revolution; and the transference of Norway to Sweden in 1814 gave back to the Norwegians their national rights, a liberal constitu-

tion, and their sense of national unity. At first they resisted the transference. Prince Christian of Denmark headed the movement for independence, and summoned a national assembly, which at Eidsvold (17th May) drew up a liberal constitution. But Sweden marched her forces into the country, and on 10th October Christian abdicated. Charles XIII. of Sweden, having recognised the constitution, was elected king on 4th November. In 1821 the Norwegians abolished all titles of nobility. The spirit of independence and of nationality has grown stronger as the years have passed, industry has thrived, commerce has prospered and brought wealth, and, intellectually, Norway stands in the van of progress. The unanimous assertion of 'home-rule' aspirations in Norway, and the unwillingness of Sweden to make the concessions demanded, led to strained relations between the kingdoms, and the peaceful revolution in 1905, when Norway resumed complete independence. Jan Mayen was annexed in 1920. In the same year Norway signed, and in 1924 ratified, a treaty placing Spitsbergen (with Bear Island) under Norwegian sovereignty. Spitsbergen became part of the kingdom of Norway in August 1925.

Michell, *History of the Scottish Expedition to Norway in 1612* (1886); and Powell and Vigfusson, *Corpus Poeticum Boreale* (1883). Carlyle's *Early Kings of Norway* (1878) is adapted from Laing's *Heimskringla*.

Literature.—Like Germany, Norway has an ancient and a modern period of literary history—the interval between being mostly blank. The ancient period of Norwegian literature is that of the Sagas (q.v.), and see also ICELAND, SNORRO, EDDA. What writers Norway gave birth to between the 13th and the 19th century, except Peder Dass (1647-1708) and Dorothea Engelbretsdatter (1634-1716), are counted amongst the Danes, in whose language they wrote. These men, Holberg, Tullin, Wessel, Fasting, Brun, Frimann, and others—some of them the brightest ornaments of Danish literature—have been already mentioned under Denmark (q.v.).

The modern period begins with the re-awakening of the national life; it received its first impulses from the Norwegian Society, a band of patriotic men living in Copenhagen in 1772, from the founding of a native university at Christiania in 1811, and from the recovery of national independence in 1814. The earliest writers of the new era, the poets Bjerregaard, (1792-1842), M. C. Hansen (1794-1842), and Schwach (1793-1860), though the ring of patriotism is in their work, possessed little originality. The creator of the modern national literature was Wergeland (1808-45), the Schiller of his country, who believed that in the free peasant proprietor lay the hope of Norway's future, and who laboured earnestly to make him worthy of that high calling. The nebulous thought and disregard of æsthetic law and taste shown in his earlier works provoked the satirical attacks of Welhaven (1807-73), a master of poetic form, and the representative of the intellectual aristocracy of the country, the mercantile and official classes. This gave rise to a keen literary feud. But, apart from Andreas Munch (1811-84), the ladies' poet, who stands by himself, and the poets J. Moe (1813-82), Jensen (1812-67), and Th. Kjerulf (1825-88), who were more or less influenced by Welhaven, nearly all subsequent writers have worked in the spirit of Wergeland, and for the same ends. Monsen (1815-

52) wrote lyrics which sometimes approach the best of Wergeland's later work in quality. Aasen (1813-96), Vinje (1818-70), K. Janson (1841), Sivle (1857), and Garborg (1851), the *Maalstrøever*, have tried to create a literary language by collating and fusing together the various peasant dialects, the first named more especially in philological works, the others in tales and novels, and even in poetry. Garborg is a writer of striking individuality. Asbjørnsen (1812-85) and Moe, the poet, and Faye collected the folk-tales; Landstad (1802-81), the hymn-writer, and Bugge (1833-1907) collected the popular songs. Daa (1809-77) popularised the history of his country, and Vig (1824-57) laboured in the same direction in various works for the people. Schultze (1823-73), Friis (1821), Østgaard (1812-73), Magdalena Thoresen (1819-1903), and others have described well and lovingly their native land and its people. Bjørnson (1832-1910), M. Thoresen, and Lie (1833-1908) wrote good tales from the life of the provinces; the peasant tales of Bjørnson are of great merit. Eilert Sundt (1817-75) strove to educate the country-people through his treatises on their social and economic circumstances. The chief writers of the latest phase of Norwegian literature are Ibsen, Bjørnson, Lie, Kjelland (1849-1906), Garborg, Camilla Collett (1813-95), Elster (1841-81), M. Thoresen, Jæger (1854), Flood (1837), Gloersen (1838), Amalie Skram (1847-1905), Kristofersen (1851), Krogh, Gunnar Heiberg (1857), Hamsun (1859), Bojer (1873). Speaking generally, these authors (novelists except Ibsen and Heiberg) show a strenuous desire for truth, great earnestness, a strongly realistic way of looking at things, keen delight in intellectual and moral strife, remarkable directness, vigour, and freshness of style, a decided leaning to satire, and frequently, too, a charming naïveté and striking originality. The socio-satirical plays of Ibsen (q.v.) have attracted notice in all countries, made him a conspicuous personality, roused not a little keen controversy, and affected the history of dramatic literature. Best known abroad by his tales, Bjørnson (q.v.), like Kjelland and Lie, also did dramatic work, and produced some admirable poetry. Kjelland satirised the classes of whom Welhaven was the representative; he had strong cosmopolitan, especially French, tendencies. Poulsen, 'Marie,' and Marie Colban (1814-84) must be mentioned as voluminous and popular authors of works of a light character.

The best Norwegian painters have been Tide-mand (1814-76), C. F. S. Hansen (1841), Gude (1825-1903), M. Müller (1828), S. Jacobsen (1833), Munthe (1841-96), and Sinding (1842); the best sculptor, Middelthun (1820-86); the best musicians, Ole Bull (1810-80), H. Kjerulf (1815-68), Grieg (1843-1907), and Svendsen (1840-1911).

Norway Haddock. See BERGYLT.

Norwich, a cathedral city, the capital of Norfolk, and a parliamentary, county, and municipal borough, with two members of parliament and a Lord Mayor (1910), stands on the Wensum, immediately above its confluence with the Yare, 18 miles W. of Yarmouth and 114 NNE. of London. Pop. (1801) 34,975; (1881) 87,842; (1901) 111,728; (1921) 120,661. Built on the summit and slopes of a hill which gradually rises from the river, the city, with its hamlets, covers an area of 7898 acres, whereas the total circuit of the ancient defences (1294-1342) was four miles. Its narrow, winding

streets are rich in examples of early architecture—as Pull's Ferry and the Bishop's Bridge (1295), both on the river-banks; St Giles' Hospital (founded 1249); the Guildhall and the Strangers' Hall (now a folk museum), dating from the 15th century; the Music House (partly Norman, and once a residence of Sir Edward Coke); the Bridewell (Decorated and Perpendicular, *circa* 1400), now a Museum of Local Industries; the Lazar House (a Norman relic), now a branch public library; Suckling House (14th century); and the Dolphin Inn (1587). The cathedral, almost wholly Norman in style, but the growth of more than four centuries, occupies a site close to the river, and was founded in 1096 by Bishop Herbert de Losinga: its dimensions are 407 feet in length by 72 in breadth (or 178 across the transepts), and it is surmounted by a noble (Norman) tower and (Decorated) spire of 315 feet—the highest in England next to Salisbury: special features are the relics, consisting of two glorious arches, of its Early English Lady Chapel (demolished 1573-89); its cloisters, 175 feet square (1297-1430); the Decorated Beauchamp Chapel (in which is preserved the Bible used at the coronation of Queen Victoria); and the vaulted roof of the nave and transept, rich in mediæval sculptured bosses. Fine gateways to the cathedral are St Ethelbert's gate (*circa* 1272) and the Erpingham gate (*circa* 1420). Close by is the grammar-school, founded (as a Mortuary Chapel) in 1316, and famous as the place of education of Sir Edward Coke, Raja Brooke, and other celebrities; also St Andrew's Hall (Perpendicular; formerly the church of the Black Friars), in which are held the triennial musical festivals, first established at Norwich in 1824. Of the ancient castle, standing on a partly artificial mound, its massive quadrangular Norman keep (erected *circa* 1135-1154 by Hugh Bigod), is the only original portion now standing; it was used as a prison till 1887. In 1894 the castle was opened as a museum; it contains a good collection of local natural productions, and is famous for its collection of raptorial birds. On the cattle-market beneath the castle is held on Saturdays the largest cattle-market in the eastern counties. A large Roman Catholic church, St John the Baptist, was built by the Duke of Norfolk in 1894. The thirty-six old churches are for the most part built of flint, and in the Perpendicular style: those of St Peter Mancroft, St Andrew, St Giles, St Lawrence, St Michael Coslany, and St Stephen are the finest examples. Modern public buildings include the hospital (founded 1771 and rebuilt 1879-83); the Public Library (1857), which contains the old City Library, founded in 1608, and a large collection of books on Norfolk; an Agricultural Hall (1882); a Volunteer Drill-hall (1866); the Technical Institute (1899) Borrow House, presented to the city in 1913 for the purpose of a Borrow Museum; and Stuart Hall (1925) adjoining Suckling House. Formerly one of the largest seats in England of the worsted-weaving trade, the city is still noted for its textile fabrics—especially its crapes; but now the principal manufactures are those of boots and shoes, mustard, starch, ornamental ironware, whilst extensive breweries and large nursery-gardens on the outskirts of the town give employment to many hands.

Of times pillaged by the Danes, and in 878 Guthrum's headquarters, Norwich in 1004 was burned by Sweyn, and thirteen years later was held by his son Cnut. Subsequent to the Norman Conquest the principal incidents in its history have been the translation of the bishopric hither from Thetford (1094); the granting of its first charter of self-government (1194); its sacking by Louis the French Dauphin (1216); the riotous attack by the citizens on the cathedral monastery (1272); its

first representation in parliament (1298); settlements of Flemish weavers (1336) and of Dutch and Walloon refugees (from 1565); a hurricane (15th January 1361), which blew down the spire of the cathedral; John Litester's rebellion (1381); disastrous fires (1463 and 1509), on the last occasion the roof of the cathedral being destroyed; the encampment of Kett's rebels on Mousehold Heath (1549); many royal visits and outbreaks of the plague, the worst being the Black Death in 1349, when half the population is supposed to have perished, in 1602, when 3076 persons died, and in 1665, when 2251 succumbed; and the great inundation through a prodigious rainfall on 25th-26th August 1912. Among the bishops of Norwich (since 1094) have been Pandulph (the pope's legate), Salmon (the builder of the grammar-school), Bate-man (the founder of Trinity Hall at Cambridge), De Spenser ('the fighting Bishop of Norwich'), Corbet (the poet), Harsnett and Manners-Sutton (afterwards Archbishops of York and Canterbury), Wren (father of the celebrated architect), Joseph Hall, and Reynolds (the composer of the General Thanksgiving in the Prayer-book). Of citizens the best known are Sir Thomas Erpingham (builder of the gate which bears his name, and chamberlain to Henry IV.); Thomas Bilney; Archbishop Parker; Dr Caius; Greene (the poet and dramatist); Bishops Cosin and Tanner; Sir Thomas Browne; 'Old' Crome, his son, Cotman, Stark, and Vincent (the 'Norwich school' of painters); Mrs Opie; Crotch (the musical composer); Wilkins (architect and R.A.); William Taylor (q.v.) and Professor Brewer; Sir W. J. Hooker; Gurney (the philanthropist) and his sister, Elizabeth Fry; Lindley (the botanist); and Harriet Martineau and her brother James.

Dicks (1906); Hawkins's *Norwich, a Social Study* (1910); Clayton's *Robert Kett and the Norfolk Rising* (1912); Stephen's *Guide to the Study of Norwich: a Select Bibliography* (1919); Hannah's *Heart of East Anglia* (1914); Henderson's *Story of Norwich* (1917); and works cited at Norfolk.

Norwich, capital of New London county, Connecticut, is at the head of the Thames River, 13 miles N. of New London; the chief part of it on an eminence between the Yantic and Shetucket rivers, which join to form the Thames. There are numerous and varied manufactures. Abundant water-power is supplied by the branches of the Thames. The land on which the city stands was granted by Uncas the Mohican to an English ensign who in 1656 reached him by night with a canoe-load of provisions, when he was besieged in his stronghold by the hostile Indians, and nearly forced by hunger to surrender: a granite obelisk bearing the name of Uncas was erected in 1825. Pop. 30,000.

Norwood, a district in the boroughs of Camberwell, Lambeth, and Croydon, hilly, healthy, and pretty, long the seat (until 1797) of a Gypsy settlement.

Nose, the organ of smell, and also part of the apparatus of respiration and voice. Considered anatomically, it may be divided into an external part—the projecting portion, to which the term *nose* is popularly restricted—and an internal part, consisting of two chief cavities, or *nasal fossæ*, separated from each other by a vertical septum, and subdivided by spongy or turbinated bones projecting from the outer wall into three passages or *meatuses*, with which various cells or *sinuses* in the ethmoid, sphenoid, frontal, and superior maxillary bones communicate by narrow apertures.

The external portion of this organ may be described as a triangular pyramid which projects from

the centre of the face, immediately above the upper lip. Its summit or root is connected with the forehead by means of a narrow bridge, formed on either side by the nasal bone and the nasal process of the superior maxillary bone. Its lower part presents two horizontal elliptical openings, the *nostrils*, which overhang the mouth, and are separated from one another by a vertical septum. The margins of the nostrils are usually provided with a number of stiff hairs (*vibrissæ*), which project across the openings, and serve to arrest the passage of foreign substances, such as dust, small insects, &c., which might otherwise be drawn up with the current of air intended for respiration. The skeleton or framework of the nose is partly composed of the bones forming the top and sides of the bridge and partly of cartilages, there being on either side an upper lateral and a lower lateral cartilage, to the latter of which are attached three or four small cartilaginous plates, termed *sesamoid cartilages*; there is also the cartilage of the septum which separates the nostrils, and in association posteriorly

Fig. 1.—Longitudinal Section of the Nasal Fossæ of the Left Side, the Central Septum being removed:

1, frontal bone; 2, nasal bone; 3, part of ethmoid bone; 4, sphenoidal sinus. *a*, superior turbinate bone; *b*, superior meatus; *c*, middle turbinate bone; *dd*, middle meatus; *e*, inferior turbinate bone; *ff*, inferior meatus; *gg*, a probe passed into the nasal duct.

with the perpendicular plate of the ethmoid, and with the vomer, forms a complete partition between the right and left nasal fossæ. It is the lower lateral, termed by some writers the alar cartilage, which by its flexibility and curved shape forms the dilatable chamber just within the nostril. The nasal cartilages are capable of being slightly moved, and the nostrils of being dilated or contracted by various small muscles.

The *nasal fossæ*, which constitute the internal part of the nose, are lofty and of considerable depth. They open in front by the nostrils, and behind they terminate by a vertical slit on either side in the upper part of the pharynx, above the soft palate, and near the orifices of the Eustachian tubes, leading to the tympanic cavity of the ear.

The mucous membrane lining the nose and its cavities is called *pituitary* (Lat. *pituita*, 'rheum'), from the nature of its secretion; or *Schneiderian*, from Schneider, the first anatomist who showed that the secretion proceeded from the mucous membrane, and not, as was previously imagined, from the brain; it is continuous with the skin of the face at the nostrils, with the mucous covering of the eye through the lachrymal duct (see EYE), and with that of the pharynx and middle ear posteriorly. This membrane varies in its structure in different parts of the organ. On the septum and spongy bones bounding the direct passage from the nostrils to the throat the lining membrane contains ample and capacious submucous plexuses

of both arteries and veins, of which the latter are by far the more large and tortuous. These plexuses, lying as they do in a region exposed more than any other to external cooling influences, appear to be designed to promote the warmth of the part, and to elevate the temperature of the air on its passage to the lungs. They also serve to explain the tendency to hemorrhage from the nose in cases of general or local plethora. In this, the respiratory part of the nose, the mucous membrane

Fig. 2.—Distribution of the Olfactory Nerve on the Septum of the Nose:

1, frontal sinus; 2, nasal bone; 4, sphenoidal sinus of left side; 7, posterior opening of the left nostril; 8, opening of Eustachian tube; 9, section of soft palate; 10, section of hard palate. *a*, olfactory nerve; *b*, its three roots; *c*, its bulb; *d*, nasal branch from the ophthalmic division of the fifth nerve; *e*, naso-palatine nerve; *g*, *h*, its branches; *i*, the septum of the nose.

is lined by ciliated epithelium. In the upper third of the nose—which, as the proper seat of the sense of smell, may be termed the *olfactory region*—the mucous membrane is very thick and coloured by a brown pigment. The olfactory nerve, or nerve of smell, terminates in the olfactory mucous membrane. It passes into the nasal cavity in several small branches; these ramify in the soft mucous membrane (fig. 2), and end in tiny varicose fibres which terminate in elongated epithelial cells projecting into the free surface of the nose. These cells—the olfactory cells—which in some animals are provided with little hairs, are affected by odorous particles, and the excitement thus set up travels to the brain by the branches of the olfactory nerve. In order to smell a substance it must be in the form of vapour or dissolved in fluid. Adequate stimuli for smell are chemical in their nature, and the odoriferous substances must come into direct contact with the olfactory surface before the olfactory end-organs can be excited. So sensitive is the nose, however, that odorous particles of inconceivable smallness are capable of producing powerful sensations. When we remember that a grain of musk will scent the air in its neighbourhood for years, and that this can only be by the continual loss of particles of its substance, these particles must be infinitely minute. Still more wonderful is the development of the sense of smell in many of the lower animals. A hare passes rapidly over the ground and the scent will under favourable circumstances remain for hours, and be sufficiently strong to enable the well-trained harrier to follow it with unerring accuracy. In savage tribes the sense of smell is vastly more acute than among civilised nations; nevertheless by practice

it is possible for any one to cultivate this sense to a very considerable extent. Well-authenticated cases are recorded of persons obliged by the loss of the other senses to train this, the only one left for their use, to such a degree of acuteness that they have been able to recognise both objects and persons by the sense of smell alone.

Most persons imagine that we are largely beholden to 'taste' for our gustatory pleasures. In reality our sense of taste only enables us to distinguish sweet from sour or bitter, and all the flavour of the food or wine is smelt. Close the nose and shut the eyes, and one cannot distinguish port from sherry, a raw potato from an apple, or beef from mutton.

There is as yet no true scientific classification and scale of odours. We are not even able to distinguish the different qualities of odours by different names, and to express them we employ the names of the vegetable or animal substances from which they emanate. Neither can we differentiate odours into elementary and compound. When two equally strong odours act separately on the nasal fossæ, such as camphor and cedar oil, it is possible to perceive the one or the other alternately; the existence of a true mixed odour is possible but rare, as it readily breaks up into its components. The usual effect of mixing two odours is neutralisation if weak, conflict if strong. Smell is easily fatigued—e.g. bad drains are soon not smelt by those living near them. In daily life bad smells are often corrected by other more pleasant odours, such as that of carbolic acid in gangrene. Olfactory sensations are useful to the individual and the species, as they excite reflex acts in the motor system and the glands. Repugnant smells from putrefying food and various poisonous substances lead to their rejection or removal. Close relations exist between the olfactory sensations and the sphere of emotion, and especially can they alter that affective state of the mind we call mood; a bad smell causes irritation and impatience, a pleasant smell engenders cheerfulness. Another characteristic of olfactory sensations is their capacity to call up by imagination the memory images of distant places. We know little of the relation between the physico-chemical constitution of a body and the quality and intensity of the odours it is capable of arousing, although Haycraft and others have pointed out that the elements which form odoriferous compounds belong almost exclusively to the fifth, sixth, and seventh groups in the periodic system of Mendeléeff.

DISEASES OF THE NOSE.—Acute inflammation of the nasal mucous membrane has been already described under the title of Catarrh (q.v.).

Chronic Inflammation, Chronic Rhinitis, or Chronic Catarrh is a very common condition of the nose and may exist for years without attracting much attention; it appears to be especially frequent and troublesome in America. It usually follows upon repeated colds in the head, but may be due also to constant inhalation of dust or irritating vapours. There seems, too, to be a tendency for this type of inflammation to run in families, probably owing to some peculiarity in the formation of the nose. The mucous membrane covering the turbinated bones swells up; and, by blocking the passage to some extent as well as by producing irritating discharges, forms a source of still further irritation. Any malformation, such as deviation of the septum to one side, or the presence on it of a 'spur,' has a similar effect. The most marked symptom is increased secretion causing constant running at the nose, a feeling of 'stuffiness,' and hawking in the back of the throat. In some persons, wasting of the mucous membrane takes place after a time, the secretion lessens, and un-

pleasantly smelling crusts form in the nose (see OZENA). Dryness of the throat resulting from mouth-breathing, enlargement and redness of the outer nose, loss of smell, impairment of hearing, and constant headache across the bridge of the nose may be further unpleasant consequences. Occasionally soft polypi develop from the swollen mucous membrane and produce still greater blockage (see POLYPUS).

In treatment, much relief is gained from the use morning and evening of a nose-wash such as the following: sodium bicarbonate, 30 grains; sodium chloride, 30 grains; borax, 30 grains; white sugar, 60 grains; rose water, 8 ounces; a small quantity to be mixed with an equal quantity of hot water before use. It may be applied by means of a nasal douche or syringe, or simply snuffed up from the palm of the hand and allowed to trickle into the throat by inclining the head backwards. Much benefit is also obtained from sprays containing ichthyol, adrenalin, &c., or by the use of astringent snuff or powder. When the mucous membrane is permanently thickened, much relief is got by cauterising with the galvano-cautery, or by operations designed for straightening the septum, removal of spurs, &c. Sometimes there is a chronic catarrhal or suppurative condition in the air-spaces of the bones about the nose which communicate with its cavity, and these must be opened up, drained, and carefully washed out. The last-named condition is specially apt to affect the antrum or maxillary sinus lying in the upper jaw-bone, which is often infected from decayed upper teeth.

Bleeding from the nose, or *Epistaxis*, may be produced by direct injury, as from a blow on the nose or a scratch inside the nostrils, or it may occur in plethoric people or those with high blood-pressure and a tendency to apoplexy. In the latter type of case its occurrence may be very salutary. If the bleeding proves excessive, it may often be stopped by placing the patient in a sitting position with the head slightly inclined backwards near an open window, by the application of cold to the back of the neck and of cold cloths to the head, and gentle pinching of the nostrils to prevent the passage of air back and forth. If this is not sufficient, pledgets of lint soaked in tincture of perchloride of iron, alum solution, hazeline, or other styptic, may be pushed up each nostril. If this is still insufficient, the back of the nose may be plugged by means of similar pledgets of lint introduced through the mouth.

Foreign bodies such as pieces of pencil, buttons, peas, or small stones are sometimes introduced by children into the nostril and slip readily beyond reach. For a time the foreign body may remain firmly impacted in the nose and cause no trouble. But in course of time a troublesome inflammation with discharge from one nostril takes place. To remove the stone, pea, &c., it is often sufficient to close the opposite nostril, and by tickling with a feather the nostril concerned, or by giving a pinch of snuff, a vigorous sneeze is produced which dislodges the body. If this fails, removal by a medical man with the help of a speculum and a bright light is a comparatively easy matter.

Nosology (Gr. *nosos*, 'disease') is that branch of medicine which treats of the distribution and arrangement of diseases into classes. See DISEASE.

Nossi-Bé, or NÔSIBÉ, a volcanic mountainous island on the north-west coast of Madagascar (q.v.) belonging to the French; area, 130 sq. m.; pop. 35,000.

Nostalgia (Gr. *nostos*, 'the return home'; *algos*, 'pain'), a technical term for home-sickness which, when, as sometimes, it takes the form of acute

melancholia, becomes ruinous to health, and even fatal. It is said that inhabitants of mountainous countries suffer more keenly than others; but it seems to have less to do with affection for the physical features of home than with inability to break with old habits and modes of life. In armies it has been found necessary to adopt measures to prevent desertion on this ground. In Canada the playing of *Lochaber no Mcre* by the pipers of Highland regiments had to be interdicted; and so in France it was forbidden under pain of death to sing or play the *Ranz des Vaches* in the hearing of Swiss mercenaries.

Nostoc, a genus of Algae belonging to the Cyanophyceæ, found upon moist ground, rocks near streams, &c., and consisting of a somewhat gelatinous hollow tumid frond, filled with simple filaments resembling strings of beads. *N. commune* is frequent in Britain, springing up suddenly on gravel-walks and pasture-grounds after rain. It is a trembling, gelatinous mass, often called Star Jelly, and vulgarly regarded, owing to the suddenness with which it makes its appearance, as having fallen from the skies (cf. Dryden, 'The shooting-stars end all in purple jellies'), and as possessed of important medicinal virtues. *N. edule* is employed in China as an article of food. Some species live in symbiosis with fungi as Lichens (q.v.); some within Liverworts (*Anthoceros*, &c.), Cycad roots, and elsewhere.

Nostradamus, the assumed name of Michel de Notredame, an astrologer of Jewish descent, who was born at St Remi in Provence, 14th December 1503. He studied at Avignon, and next medicine at Montpellier, took the degree of doctor of medicine in 1529, and practised the profession at Agen, afterwards at Salon near Aix. Next year when the plague was raging at Lyons he was conspicuous for his skill and devotion. He first felt upon his prophetic vein about the year 1547, but in what light he himself regarded his pretensions it is now impossible to say. The first collection of famous *Centuries* appeared at Lyons in 1555. These were predictions in rhymed quatrains, divided into centuries, of which there were seven; the second edition, published in 1558, contained ten. Astrology was then the fashion, and these quatrains, expressed generally in obscure and enigmatical terms, brought their author a great reputation. Catharine de' Medici invited him to visit her at Blois; the Duke and Duchess of Savoy went to Salon expressly to see him; Charles IX. on his accession appointed him his physician-in-ordinary. Nostradamus died at Salon, 2d July 1566. His predictions have given rise to a vast illustrative or controversial literature. The *Centuries* were formally condemned by the papal court in 1781.

See Jaubert's *Vie de M. Nostradamus* (Amst. 1656); Haitze's *Vie de Nostradamus* (Aix, 1712); Astruc's *Mémoires pour servir à l'Histoire de Montpellier* (1767); *Apologie pour les Grands Hommes Soupçonnés de Magie* (Paris, 1825); E. Bareste's *Nostradamus* (1842); and Charles A. Ward's *Oracles of Nostradamus* (1891).

Notables, the name formerly given in France to persons of distinction and political importance. As the States-general were inconvenient to the despotism of the monarchy, the kings of the House of Valois adopted the expedient of calling in their stead *Assemblies of the Notables*, the time of calling them and the composition of them being entirely dependent on the pleasure of the crown. For more than a century and a half even this poor acknowledgment of any other mind or will in the nation than that of the sovereign ceased to be made; but when the state of the finances brought the monarchy into difficulties and perils Louis XVI., at the instigation of the minister Calonne, had re-

course again to an Assembly of Notables, which met 22d February 1787, and was dissolved 25th May. It consisted of 137 members, among whom were seven princes of the blood, nine dukes and peers, eight marshals, eleven archbishops, twenty-two nobles, eight councillors of state, four masters of requests, thirty-seven judges, twelve deputies of the Pays d'États, the civil lieutenant, and twenty-five persons belonging to the magistracy of different cities. See LOUIS XVI., NECKER, FRANCE.

Notary public is an officer of the law or professional person whose chief function is to act as a witness of any solemn or formal act, and to give a certificate of the same; which certificate, if duly authenticated, is accepted as good evidence of the act done in his presence, and attested by him. Under the Law Agents Amendment Act, 1896, no person can now be admitted as a notary-public in Scotland until he shall have been admitted and enrolled as a law agent. The English courts take notice of the seal of a notary, but his certificate is not generally received as proof of the facts certified. A notary is employed in the noting and protest of foreign bills of exchange in case of non-acceptance or non-payment. In the United States the powers of notaries are defined by the state laws.

Notation. For Chemical Notation, see CHEMISTRY; for Musical, MUSIC, SOLFEGGIO; for Mathematical, NUMERALS, ALGEBRA, CALCULUS, GEOMETRY, QUATERNIONS, SCALES OF NOTATION.

Noto. an ancient episcopal town of Sicily, 16 miles SW. of Syracuse by rail; pop. 32,000.

Notochord. See EMBRYOLOGY, AMPHIOXUS.

Notodden, a town of Norway, in Telemark, at the north of Lake Hiterdal, 60 miles SW. of Oslo, near the great Tinfoss cascades, which provide ample power for generating electricity largely used in the production of nitrates, &c.; pop. 6500.

Notornis, a genus of the Rail family, with wings so much reduced as to be incapable of flight, has within historical times become partially or completely extinct. Notornis inhabited New Zealand, and within the 19th century four specimens were taken, one of them in 1898, so that possibly there are still a few survivors in out-of-the-way districts. *N. alba* was soon exterminated in Lord Howe Island.

Notoryctes, MARSUPIAL MOLE or URQUAMATA, a blind central Australian marsupial, discovered in 1882, is a pale yellow silky-haired animal, with great digging claws on its third and fourth fingers, that feeds on insects under the sand. The eyes are covered with skin and muscle. The dentition is peculiar. The pouch opens backwards. The single species (*N. typhlops*) forms a family by itself.

Nototherium, a genus of gigantic fossil kangaroo-like marsupials, found in Australia (q.v.).

Not Proven. See CRIMINAL LAW.

Notre Dame (Old Fr., 'Our Lady'), the name of many churches dedicated to the Virgin Mary in France, particularly the cathedral of Paris.

Nottingham, a city of England, the capital of Nottinghamshire, and a parliamentary, municipal, and county borough (the first returning four members), is seated on the Trent, 126 miles NNW. of London, 15 E. of Derby, and 38 S. by E. of Sheffield. Formerly surrounded by ancient walls (910-1265), of which all traces have now disappeared, the town covers an area of about 16 sq. m., and its appearance of late years has been much improved by the widening of its streets; by the erection of a new town-hall, University College,

and other public buildings; by the opening and laying out of an arboretum of 17 acres, of a public park and recreation grounds of over 150 acres, and of a tract of open land, called 'Bulwell Forest' (135 acres); as also by the spanning of the Trent—which is here about 200 yards wide—with a broad granite and iron bridge in the place of a former narrow structure of seventeen arches. Crowning a precipitous rock, which rises 133 feet above the river, stands the castle, built (1674-83) on the site of an ancient Norman fortress, dismantled during the Parliamentary wars, and itself much damaged by fire during the Reform Bill riots of 1831. It was restored in 1878, and transformed into an art museum. Near to it are the county hall (1770); St Mary's Church (restored 1867-85), a cruciform building in the Perpendicular style, 216 feet in length; and a spacious market-place, 5½ acres in extent, having at its eastern end the exchange, with a richly-decorated façade (rebuilt 1814). In another group not far off are the guildhall and other municipal offices (1888), in the French Renaissance style of architecture; two theatres (1865-84); and University College (1879-81), with well-equipped technical schools and a natural history museum; it received a charter of incorporation in 1903. Other edifices worthy of mention comprise a hospital (1781, with additions 1829-79); a Roman Catholic cathedral (1844), cruciform and Early English; and the high school, founded as a grammar or free school in 1513; it is largely endowed, and annually offers for competition eight exhibitions of a value of £435, besides scholarships. There is also a municipal school of art. Nottingham aspires to a university and a port; and improvement of the Trent waterway has been undertaken. In 1870-84 Nottingham was the seat of a suffragan bishop under Lincoln. On the outskirts race-meetings were held annually in March and October for a hundred years until 1890; the Trent Bridge cricket-ground is the scene of the county's home matches; whilst mention must not be omitted of the annual goose fair held at Michaelmas. Of the various manufactures carried on in the town the most important are those of lace and hosiery; baskets, bicycles, cigars, and needles are also made, whilst several iron-foundries are in operation, and malting and brewing are extensively carried on. One of the most successful sewage farms in the country has been laid out 5 miles from the town, the whole of whose sewage is here dealt with. Pop. (1801) 28,801; (1831) 50,220; (1891) 213,984; (1921) 262,658. In the history of Nottingham, which was one of the Five Boroughs, the principal incidents have been its occupation by the Danes, and their withdrawal on the conclusion of a treaty for peace (868); its destruction by fire (1140 and 1153); the granting of its first charter (1155); the convening of three parliaments (1330-37); the appointment of its first suffragan bishop (1534); the raising by Charles I. of his standard at the commencement of the Parliamentary war (1642); and riots (1795-1816), partly on account of a bread famine and partly owing to the Luddites (q.v.). See the borough *Records* (1882-1900), works by Dickinson (1816), Wylie (1853-65), Hine (1876), W. H. Stevenson (4 vols. 1890), and Guilford (1920), besides those cited under the county.

Nottinghamshire, or NOTTS, an inland county of England, bounded on the N. by Yorkshire, E. by Lincolnshire, S. by Leicestershire, and W. by Derbyshire. Its greatest length is 50 miles; average breadth, 20 miles; and area, 844 sq. m., or 540,123 acres. Pop. (1801) 140,350; (1831) 225,400; (1891) 445,823; (1921) 641,134. Apart from the valley of the Trent, which is very flat, the general aspect of the county is undulating and well wooded, the highest ground—600 feet above the sea-level—being in the

west, in the vicinity of Sherwood Forest (q.v.). In the south are the Wolds, consisting of upland moors and pasture-lands broken up by many fertile hollows, whilst the northern boundary for upwards of 15 miles is skirted by the Car, a tract of low-lying land, formerly a swampy bog, but since 1796 drained and brought into cultivation. The Trent, with its tributaries, the Erewash, Soar, and Idle, is the principal river, and the Fosse Dyke and Notts and Grantham canals, and London, Midland, and Scottish, and London and North-eastern railways also traverse the county. The climate, especially in the east, is remarkably dry and the soil varies, sand and gravel, clay, limestone, and coal-land prevailing in different districts. In productiveness it is not above mediocrity, except in the Vale of Belvoir to the east of Nottingham. The cultivation of hops has been discontinued. The principal mineral products are coal, gypsum, iron ore, and limestone. The manufactures are noticed under the chief towns—viz. Nottingham, Newark, Mansfield, Retford, and Worksop, the two former also being the scene of most of the historical events connected with the county. Notts returns nine members to parliament, one for each of its five divisions (Bassetlaw, Newark, Mansfield, Broxtowe, and Rushcliffe), and four for Nottingham (its capital and assize town). Of its natives the best known are Archbishops Cranmer, Secker, Sterne, and Manners-Sutton; Garnet (the Jesuit); Denzil Lord Holles; General Ireton, and his contemporary Colonel Hutchinson; Lady Mary Wortley Montagu; Bishop Warburton; Dodsley, Kippis, and Wakefield (the authors); Admiral Earl Howe; Sandby and Bonington (the artists); Dr Erasmus Darwin; Edmund Cartwright; Fynes Clinton; Kirke White, Byron, 'Festus' Bailey; Speaker Denison; 'General' Booth; Samuel Butler (the author of *Erewhon*); D. H. Lawrence.

See county histories by Thoroton (1797), Bailey (1852-55), Briscoe (1881), White (1885), C. Brown (1891), and the 'Victoria History' (1906 *et seq.*).

Nouméa, capital of New Caledonia (q.v.); pop. 9000.

Noun. See GRAMMAR.

Novalis, the pen-name of Friedrich von Hardenberg, German writer, who was born at Wiedersdorf, near Mansfeld, in Prussian Saxony, 2d May 1772. Whilst being educated at Jena, Leipzig, and Wittenberg he came under the influence of Schiller, and became acquainted with Fichte, Fr. Schlegel, and Tieck, studied deeply the works of Boehme, and imbibed himself with the spirit of Romanticism to such an extent that he was afterwards designated the 'Prophet of Romanticism.' He made his start in life as a mining official. At Weissenfels (1795) he fell in love with a beautiful young girl, whose early death left a lasting impression upon him. Ere many years were past he himself, delicate from his boyhood up, was seized with consumption, and died 25th March 1801. The principal tenets of his two philosophical romances, both left incomplete, *Heinrich von Ofterdingen* and *Die Lehrlinge zu Saïs*, were that life ought to be poetry realised in practical conduct, and that there are in the universe many verities and realities the truth of which cannot be grasped by the cold, critical intellect; they can only be known by the sympathetic intuition of feeling. His *Hymnen an die Nacht* are a glorification of his sorrow at the loss of his mistress. These, together with his *Poems* and *Sacred Songs*, are the only finished productions he has left. Novalis penned many thoughtful and suggestive sentences, often in very graceful language; but on the whole his writings lack precision of thought and robust common sense; their prevailing atmosphere is

a mystic twilight, where is much obscurity, but also much beauty and much deep feeling. His *Sämmtliche Werke* (2 thin vols.) were published by Tieck and Fr. Schlegel in 1802. To these a third volume, containing a supplement to the *Life* printed in vol. i., together with poems and philosophic fragments by Novalis, was added in 1846. See Carlyle, *Miscellaneous Essays* (vol. ii.), the German *Life* published at Gotha (2d ed. 1883), E. Heilbronn, *Novalis der Romantiker* (1901), and Novalis's correspondence with the Schlegels (Mainz, 1880).

Novara, capital of a North Italian province, 60 miles N. of Turin by rail, with a colossal cathedral (rebuilt 1831), several fine churches, a trade in silk, grain, and wine, and manufactures of silk, cotton, and linen. Here the Sardinians were utterly defeated by the Austrians under Radetzky on 23d March 1849. Pop. 56,000.

Nova Scotia, a province of the Dominion of Canada, lying between 43° 25' and 47° N. lat. and 59° 40' and 60° 25' W., long., consists of a long, narrow peninsula, and the island of Cape Breton, which is separated from the mainland by the Strait of Canso. It is bounded on the N. by Northumberland Strait, which separates it from Prince Edward Island, and by the Gulf of St Lawrence; NE., S., and SE. by the Atlantic Ocean; W. by the Bay of Fundy; and NW. by New Brunswick, with which it is connected by an isthmus only 15 miles wide, separating Chignecto Bay, the north-western branch of the Bay of Fundy, from Northumberland Strait.

The greatest length of the province is 386 miles, the greatest breadth about 100 miles, and the area, including the Bras d'Or Lakes (360 sq. m.) in Cape Breton Island, 21,428 sq. m.—one-third less than that of Scotland. Pop. (1806) 67,515; (1851) 276,117; (1871) 387,800; (1891) 450,523; (1901) 459,574; (1911) 492,338; (1921) 523,837. The principal cities and towns are Halifax, the capital (58,000), Sydney (22,500), Glace Bay (17,000), Amherst, New Glasgow, Sydney Mines, Dartmouth, Truro, Yarmouth.

The coast-line is about 2000 miles in length, and the shores abound with excellent harbours. There are numerous rivers, but few of them are more than 50 miles long. The most important are the Avon, Annapolis, Shubenacadie, Lahave, and Margaree. Among the lakes the chief is Great Bras d'Or Lake, really a landlocked arm of the sea, about 50 miles long, with an area of about 230 sq. m., and a depth of water varying from 12 to 60 fathoms. The next largest lakes are Lake Rossignol, 20 miles in length; Ship Harbour, 15 miles long; Lake Ainslie; and Grand Lake. The most remarkable body of water in the province is Minas Basin, the east arm of the Bay of Fundy (q.v. for its tides), penetrating 60 miles inland, and terminating in Cobequid Bay. The country is beautifully variegated by ranges of hills and broad valleys, both of which run longitudinally through the province. The Cobequid mountains, as they are called, run through the interior of the province. On each side of them are rich arable lands. The Annapolis valley is especially favourably situated. The southern part of Cape Breton is very much the same in appearance as the northern part of the mainland, but the northern part of the island is bold and steep, the land at Cape North being 1800 feet above the sea-level. The distance from Cape North to Cape Ray on the Newfoundland coast is 60 miles.

The climate of Nova Scotia is remarkably temperate considering its northern latitude. The extreme of cold is 20° below zero, and the extreme of heat 94° in the shade. The western counties

average from 6 to 8 degrees warmer than the eastern, and in Annapolis county the mercury rarely falls below zero. Vegetation is very rapid, and the autumn forms a delightful season. Spring is rather tedious, and the winter variable. Fogs are prevalent along the coasts, but do not penetrate inland to any extent.

Agriculture and horticulture are among the principal industries in the province. Oats and buckwheat, Indian corn, tomatoes, potatoes, turnips, and all root-crops grow in abundance. Wheat is grown to some extent. Apples, pears, plums, cherries, and other garden fruits attain the utmost perfection. The apple-orchards in Annapolis and Kings counties are famous. They extend along the roadside in an almost unbroken line for 100 miles, and in the autumn form a sight not soon forgotten. More attention than formerly is now being devoted to dairying and to the raising of live-stock. The manufactures of the province are yet limited, but are being developed. Cottons and woollens are manufactured in various parts of the country. There are iron-works at Londonderry, steel-works at Sydney and New Glasgow, and stove and hardware works at Amherst; and there are also several sugar-refineries, paper-mills, boot and shoe and other manufactures of leather, manufactories of agricultural and other machinery, of furniture and wooden ware, and many sawmills. The shipbuilding industry was formerly a most important one, but has suffered from the substitution of iron for wooden vessels. Mining is extensively carried on. The production of gold has fallen off. Coal and iron are abundantly distributed and extensively worked. Notwithstanding that the export of coal to the United States fell off considerably when the reciprocity treaty with that country came to an end in 1866, the output of coal did not decrease, the falling off in the United States trade being more than counterbalanced by the great increase in the consumption in the Dominion. Now Nova Scotia furnishes about a third of the Dominion's yield. Other minerals are also abundant, including silver, manganese, gypsum, antimony, copper, slates, granites, sandstones, and several varieties of precious stones. The fisheries of Nova Scotia are regarded as among the finest in the world. A large number of men and boats are engaged in the industry. The waters abound with mackerel, cod, herring, shad, salmon, halibut, haddock, lobsters, &c. The chief exports of Nova Scotia are fish-products, minerals, lumber, agricultural products, and general manufactures.

There are 1450 miles of railway in the province, which is connected with both the Canadian and United States railway-systems. There are two canals in the province, one from Halifax to Cobequid (not now in use), and the other connecting St Peter's Bay and Bras d'Or Lake. The maritime situation is very favourable for sea-borne trade, the coast-line has many deep indentations, and the harbours on the Atlantic and Bay of Fundy coasts are accessible to shipping all the year round.

The religious denominations according to the census in 1921 were as follows: Roman Catholics, 161,000; Presbyterians, 110,000; Baptists, 87,000; Anglicans, 86,000; Methodists, 59,000. Education is free, and there are numerous public schools and academies, besides a normal school, technical schools, several convents, Dalhousie University, Halifax; Acadia University (Baptist), Wolfville; St Francis University (Roman Catholic), Antigonish; and King's College University, Windsor. The last, belonging to the Church of England, was founded in 1787. Its buildings were burned down in 1920.

The public affairs of the province are administered by a lieutenant-governor, and legislative council of

twenty-one members, and a house of assembly of forty-three members elected by the people for four years. The province is represented in the Dominion parliament by ten senators and fourteen members of the House of Commons.

Unlike some of the provinces, Nova Scotia has but little land available for agricultural purposes that may be given by a grant from the crown. Throughout the province, however, many farms with buildings already erected are available at moderate prices to make comfortable homes. Excellent shooting and fishing are to be found all over the province, especially in the less accessible parts, where big game is still fairly abundant.

History.—Nova Scotia was first visited by Cabot in 1497, and the first colonisation recorded is that in 1604 of the French under De Monts, who attempted for some years to form settlements at Port Royal—now Annapolis—St Croix, &c. The settlers were finally expelled by the English colonists of Virginia, who claimed the country by right of the discovery of Cabot. Other attempts were made at colonisation, but with small success. The country was ceded to France by the treaty of Breda in 1667; its possession, however, remained a source of contention between England and France, until it was finally ceded to England by the treaty of Utrecht in 1713. A memorable event in the history of the province was the expulsion of the Acadians (see ACADIA) in 1755. Cape Breton was the scene of many struggles between the French and British, especially in the neighbourhood of Louisburg (q.v.). In 1763 it was annexed to Nova Scotia. It was subsequently made a separate province, but again united to Nova Scotia in 1819. Many attempts were made to develop Nova Scotia, but the foundations of its present position date from the immigration in 1784 of the loyalists who preferred to take up their homes in British territory rather than remain under the sovereignty of the United States. The province of New Brunswick was created in 1784 out of Nova Scotian territory.

See Haliburton's *Nova Scotia* (1829), Murdoch's *History of Nova Scotia* (1867), Hannay's *Nova Scotia* (1879), Kingsford's *History of Canada* (1889), and Bourinot's *Builders of Nova Scotia* (1900).

Novatian, a priest of the Roman Church in the 3d century, and the leader of a sect called after his name. The place and time of his birth are not known with certainty. Novatian is said to have been a stoic philosopher, but after his arrival in Rome was converted to Christianity, and, being seized with sudden illness while still a catechumen, received what was called *clinical baptism*—i.e. baptism administered on a sick-bed and without the solemn ceremonial. Such baptism was in ordinary circumstances an impediment to holy orders. Notwithstanding this irregular baptism, Novatian was promoted to orders by Fabian the Roman bishop, and soon acquired great reputation by his learning and eloquence. Soon after the Decian persecution a great controversy arose about the manner of dealing with the lapsed—i.e. those who fell away during persecution. Novatian at first inclined to the milder side, but on the election of Cornelius to the Roman bishopric (March 251), and on Cornelius taking the indulgent course towards the lapsed, Novatian, together with Novatus and some other discontented priests of Carthage, opposed his authority, and eventually Novatian was chosen by a small party and actually ordained bishop in opposition to Cornelius. The party who espoused his cause was called by his name. They were confined mainly, in the first instance, to Rome and to Carthage, where a similar conflict had arisen. They held that in the grievous sin of idolatry through fear of persecution the church had no power to absolve

the penitent; and therefore, although it does not appear that they excluded such sinners from all hope of heaven, yet they denied the lawfulness of readmitting them to the communion of the church. This doctrine they extended at a later period to all grievous sins of whatever character. In this view the church was merely a community of saints whose very existence is endangered by the presence of one sinner. Cyprian (q.v.), at first rigorous against the lapsed, gradually abated his severity.

Novatian may thus be regarded as the first antipope. The churches throughout Italy, Africa, and the East adhered to Cornelius; but the Novatian party set up bishops and established churches not only at Carthage, but at Constantinople, Alexandria, Nicomedia, in Phrygia, Gaul, Spain, and elsewhere. They claimed for themselves a character of especial purity, and assumed the appellation of Cathari (Puritans). The time and manner of the death of Novatian is uncertain. According to Socrates he died a martyr in the persecution of Valerian, but this is improbable. His sect survived long after his death. An unsuccessful effort was made in the Council of Nice to reunite them to the church; and traces of them are still discoverable in the East down to the end of the 6th century. See the *Letters* of Cyprian, Eusebius; also Walch's *Ketzerhistorie* (vol. ii.).

Novaya Zembiya, an Arctic land belonging to Russia, lying between the Kara Sea and Barents Sea, and separated at its southern extremity from the island of Vaigatch by Kara Strait, 30 miles wide. Long and narrow, it measures 600 miles from north to south and 60 in average width, and is cut in two nearly midway up by a narrow winding sea-passage, the Matchkin Shar. The western side is broken by several bays, often studded with islands. The interior is mountainous throughout, the mountains, covered with snow and ice, rising to 4000 feet or more. The rocks are Cambrian, Devonian, and Permo-Carboniferous. The continuation of the Gulf Stream reaches the western shores and prevents them from being always icebound. Almost without permanent inhabitants, it is visited by Russian and Norwegian seamen and hunters for the capture of the numerous sea-fowl, whales, walrus, seals, and dolphins which frequent its coasts. It was known to the hunters of Novgorod in the 11th century, but was rediscovered by Sir Hugh Willoughby in 1553. A Norwegian scientific expedition under Professor Høltedahl visited it in 1921.

Novellæ. See JUSTINIAN.

Novello, VINCENT, musical composer and publisher, was born in London, of an Italian father and English mother, on 6th September 1781. He officiated as organist in various chapels in London, and was one of the founders of the Philharmonic and similar musical societies. His musical compositions, chiefly sacred, are considered to have contributed much to the improvement of cathedral music. But it is as a painstaking editor of unpublished works of eminent musicians that he deserves chiefly to be remembered. He died at Nice, 9th August 1861.—His daughter, CLARA ANASTASIA, a distinguished vocalist, was born in London in 1818; won great triumphs in many great cities; married Count Gigliucci in 1843; quitted the stage in 1860; and died at Rome 12th March 1908. See her *Reminiscences* (1910).

Novels. 'Novel,' as the name of a thing, came to us with the thing itself from Italy early in the reign of Elizabeth. Boccaccio, from whom Painter took the 'excellent novelles' in his *Palace of Pleasure*, applies 'novella' somewhat indiscriminately, and in his preface speaks of 'novels or fables

or parables or stories' as if they meant pretty much the same thing; but in Provençal, and according to the *Cento Novelle Antiche*, 'noella' or 'novella' seems to have meant originally some new drollery, jest, or bon-mot—something, as Borghini explains, that pleased by its freshness, and the 'noellaire' or 'novellatore' to have been a kind of jester who collected and retailed such things. Most of the *Cento Novelle* and a large number of Boccaccio's, notably those of the sixth, seventh, and eighth days, are of this sort, and in the collections of Sacchetti and Ser Giovanni the proportion is still greater. In fact the primitive novella was something much more akin to the *facetiae* of Poggio, the *Cent Nouvelles nouvelles*, the stories of the *Heptameron*, the *Hundred Merry Tales*, and even their humble relatives, the jests attributed to Joe Miller, than to the long, grave, and often tragic narratives that appeared under the title when it had grown elastic in the 16th century. But if 'novel' has departed from its original signification, 'romance' has wandered still farther. The word originally had nothing whatever to do with any form or species of composition. It was simply the name given in the middle ages to the spoken language of the commonalty, particularly in France and Spain, in contradistinction to the Latin or Letra, the language of the learned classes and the language used in documents and writings of all kinds. In time, however, it came to mean not only the vehicle but also the thing conveyed; anything in Romance was called romance, and naturally the term was extensively applied to the great source of popular recreation, the songs of the minstrels and *trouvères*, by which it was in the end almost monopolised. Hence the two meanings of 'romance' in Spanish—(1) the vernacular ('en buen Romance' is the precise equivalent of our phrase 'in plain English'); (2) a piece of popular narrative poetry such as we mean by the word 'ballad.' In France the place of the ballad was supplied by much longer and more elaborate compositions, like the *chansons de geste*, and to these the title of 'romans' was very generally given. But it is noteworthy that, 'romance' or 'romans,' it was applied, in Spain exclusively and in France all but exclusively, to compositions in verse, and that the prose-works which we now call the romances *par excellence* were not so styled in their own time. The romances of chivalry were called by their authors or editors chronicles, histories, or books; but, except in one edition of *Lancelot*, never romances; and the still more typical romances, the heroic romances of the 17th century, *Polexandre*, *Cassandre*, *Pharamond*, *Ibrahim*, and the like, seem to have been indebted to Scarron, but certainly not to their authors, for the name. Neither 'novel' nor 'romance,' in short, has any historical or etymological claim to stand for the latest development of prose fiction; nor is there any warrant for a distinction between the novel and the romance founded on a predominance of the real or the ideal, the ordinary or the extraordinary, the comic or the tragic, a distinction which, in practice, it would be impossible to draw. The names are purely conventional. What we call a novel the French call a *roman*; if they shared our somewhat contemptuous feeling for the romantic perhaps they would have followed our example, as we perhaps might have followed theirs if, instead of bad news, we talked of hearing bad novels.

For the origin of the thing so called there is no need to search very far. To ask where fiction came from, or what particular race or people were the inventors of it, is very much like asking who invented singing. If we must find a source for it, or fix it upon someone, a child in a corner telling a

story to itself, with its playthings for *dramatis personæ*, or Maggie Tulliver unfolding the tale of the earwig's domestic troubles to her cousin Lucy, will be as near the fountain-head of fiction as we need go. The demand for fiction seems to follow very closely upon the demand for food. 'Tell me a story' is among the earliest expressions of our wants in life, and so far as we can see it has been, one from time immemorial, and everywhere and always story-tellers of one sort or another are to be found striving as best they can to comply with the call. It is true that we cannot see very far back, and that our only available sources of information convey a very imperfect idea of story-tellers and story-telling in the remote past. The fragments and specimens that have come to us through tradition and literature can no more give a complete view of the fiction of the age they belong to than the fossils in a cabinet of the fauna and flora of the globe when they were living things. They have been preserved by accident, or by the possession of some property or feature conducing to preservation, while types and species less favoured have left no trace behind them of their existence. To take an example, every one at all acquainted with it must have noticed how strongly the didactic element asserts itself in early eastern fiction. By far the greater number of the specimens that have come down to us through the *Panchatantra*, *Hitopadesa*, *Bidpai*, *Lokman*, *Æsop*—for in strictness he must be counted among the Orientals—and other channels are fables with a moral attached. Now it is obvious that these cannot be the earliest type of fiction. Children call for stories, but not (in real life at least) for instruction or improvement until some years have passed over their heads; and what is true of children is true of humanity. But the very earliest productions of the fable family are entirely destitute of this appendage, and are mere stories told for their own sake. Properly they belong to a still earlier type than the fable, the story where animals and inanimate things speak and act like human beings, the immediate descendant, no doubt, of the story the child tells to itself about such objects as take its fancy (see *BEAST-FABLES*). It is easy to see how the moral came to be added, and how, once added, it became protective. The story furnished with a moral was preserved by and for the sake of its moral when those told for the story's sake alone dropped out of circulation; and in virtue of its moral it found its way into literature as soon as there was a literature to receive it. It is simply an instance of survival of the fittest; not necessarily of the best, but of the best fitted to survive in the struggle for existence.

The case of *Æsop* above referred to is an illustration of the connection between oriental and European fiction. Some critics maintain that he was an Oriental himself, and identify him with *Lokman*; but without going so far it may be safely said that the fables bearing his name are mainly of oriental origin, and from some source in common with the *Panchatantra*. But this is not the only instance. It is significant that, with scarcely an exception, Greek prose fiction came from Asia Minor, or from islands off the coast, and in most instances the Asiatic influence is distinctly perceptible. Of the Milesian tales we know little, but from that little it seems likely that they were compositions somewhat in the nature of the French *fabliaux*, and like them largely indebted to the eastern story-tellers. *Iamblichus*, the author of the *Babylonica*, and *Heliodorus*, the author of the more famous *Theagenes and Chariclea*, were both Syrians, and clearly drew their inspiration from the same quarter. *Achilles Tatius*, the follower of *Heliodorus*, was of Alexandria. *Xenophon*, who wrote the tale of

Abrocomas and Anthia, was of Ephesus. *Josaphat and Barlaam* was by John of Damascus. *Lucian* was another Syrian, but he cannot be properly included among those who wrote stories for the story's sake, nor indeed among those distinctly influenced by eastern fiction, any more than the author of the graceful pastoral of *Daphnis and Chloe*, whoever he may have been, for 'Longus' is probably a mere clerical error. As M. Chassang says, in his *Histoire du Roman*: 'The taste for the romance passed from the East to Greece;' but it was to the artistic instinct of the Greeks that the novel or romance owed the remarkable development we see in *Daphnis and Chloe* and *Theagenes and Chariclea*. The taste passed into Italy also about the same time, but more probably through the medium of the Milesian and Sybarite tales than directly from the East; and it bore fruit in the *Satyricon* of *Petronius Arbiter* and the *Metamorphosis*, or *Golden Ass*, of *Apuleius*, in each of which the best-known episode is derived from an eastern story. The *Cupid and Psyche* of *Apuleius* and *Petronius' Widow of Ephesus* are found in divers forms, and of the latter there is even a Chinese variant.

The collection of fables, partly from the *Panchatantra* and *Hitopadesa*, called *Kabila wa Dimna* had a great share in the spread of oriental stories in the middle ages throughout western Europe, but chiefly in Spain, where, introduced probably by the Arabs, it helped to furnish material for the *Disciplina Clericalis* of *Pedro Alfonso* and the *Conde Lucanor* of *Don Juan Manuel*. But even more influential was a work that still circulates as a chap-book in most European countries, *The Seven Wise Masters of Rome*, which, under a variety of titles, *Erastus*, *Dolopathos*, *Syntipas*, *Sindebad Nameh*, *Sandabar*, *The Seven Vizirs*, and through Latin, Greek, Hebrew, Arabic, and Persian, may be traced back to Sanskrit. Such collections of fables, apologies, and tales, each in a setting more or less ingenious of its own, and borrowing freely from its predecessors—story-books of a class that has been made familiar by *The Thousand and One Nights*—were very numerous at the time, and served as a mine of oriental fiction to mediæval Europe. The *Gesta Romanorum*, which is in fact a European story-book on the oriental model, was largely indebted to this source, but not nearly so much as the *fabliaux* (properly 'fableaux,' diminutive of 'fables') of the *trouvères*, who found in the inventions of the eastern story-tellers precisely the sort of tale which their easy verse and *esprit gaulois* could readily adapt to the taste of their audiences. It was from the *fabliaux* that the Italian *novellieri*, from *Boccaccio* to *Bandello*, and not only they, but also the compilers of the *Cent Nouvelles nouvelles* and of the *Heptameron*, and the gay novel-writers of the 16th century in general, chiefly took their lightest, liveliest, most satirical, and sometimes most licentious tales; and in this way the fiction of the East came in numberless instances to be incorporated in the literature of Europe.

But the *trouvères* were at the same time laying the foundations of another very different species of novel. There were audiences for whom the *fabliaux* were too light and trivial, and who demanded a lay of a more serious and earnest character and of deeper interest, and for these they had the *chanson de geste*, a sort of minor epic, dealing for the most part with the deeds or adventures of some real or legendary hero, and standing in much the same relation to the *fabliaux* as tragedy, or at least serious drama, to light comedy and farce; and from these *chansons de geste* in process of time, as reading became a more common accomplishment, and books began to take the place of the lays of the minstrels, came the prose romance

of chivalry. Not, of course, that every romance of chivalry had its origin in the verse of a *trouvère*; there is no evidence, for instance, that the story of Lancelot was ever the subject of a *chanson de geste*, though there can be little doubt that it furnished a theme for Welsh and Armorican ballads long before Walter Map took it in hand. But unquestionably the early romances of chivalry were as a rule made from earlier metrical romances, as these again, no doubt, from shorter and ruder pieces of verse; the process being, presumably, first legend or tradition, then ballads of some sort embodying incidents of the legend, then the isolated ballads connected, unified, and polished into a *chanson de geste* by a bard of a higher order, and finally the prose romance, sometimes curtailing, but oftener expanding the *chanson*. The process is well seen in the romances of the Charlemagne cycle: the connecting-link between the legend and the *chanson* has, of course, disappeared, but it has left its traces plainly visible in the *Chanson de Roland*, the germ of the whole; and we find the legends of Gascony and the Ardennes and of Charlemagne's troubles with his foes and vassals first furnishing a subject for the *trouvère*, and then passing into prose romances like *Huon de Bordeaux*, *Les Quatre fils Aymon*, *Fierabras*, and *Ogier le Danois*. Nor is it confined to the romances of chivalry proper, of Arthur and the Round Table and Charlemagne and the Peers; for the romances of the borderland between chivalry and faerie, *Parthenope of Blois*, *The Knight of the Swan*, *Melusina* (q.v.), and the like, were all apparently sung by the *trouvères* before they sought readers in prose. See ROMANCES.

The Spanish family of romances of chivalry came into the world long after the age of the *trouvères*, though it is very likely that Amadis of Gaul, the founder of it, may have made his first appearance in verse. He is mediæval, but all his progeny, which includes not merely the Amadis series, but also the Palmerins and isolated romances, are of modern birth, and a connecting-link between the novel of the middle ages and the novel of our own day. They were the products of a variety of causes—the taste created by the Amadis, the recent invention of printing, which made such reading a comparatively cheap luxury, and, above all, the condition of Spain at the time. M. Chassang, in the book already quoted, has a remark not wholly complimentary to novelists and novel-readers, to the effect that story-telling flourishes most where the people are most idle. The peoples of the East were, and still are, the most prolific of story-tellers, because, living under paternal governments, they have always had a surplus of time upon their hands. The Greeks and Romans did without stories so long as their republics lasted, for his share in the affairs of the state gave each man employment enough for his spare time and thought, and it was not till Greece became subject to Rome and Rome to the emperors that the Greek and Latin romances came into existence. This theory, if we accept it, will account for the passion for romances that raged in Spain in the 16th century, until cured by the drastic remedy of Cervantes. The end of the great national struggle with the Moors, the establishment of the Inquisition, the absorption of all political power and authority by the sovereign, and the general stagnation in public life left the upper and middle classes to a great extent without occupation. Only a few could follow Cortes and Pizarro, and the majority had to resign themselves to inaction, made all the more irksome by the memories of a stirring past, and warm their blood as best they could with the imaginary adventures and sound and fury of the chivalry romances. The chief charge brought by

every assailant of these productions, from Pedro Mexia to Cervantes, is that they infected their readers with their own extravagance, and made them think in their style and fancy themselves acting the scenes they read of. But this was the great attraction; they were indulged in, like bhang or opium, for the sake of the pleasant insanity that attended indulgence. Don Quixote's madness, if an extreme, was not a solitary case; and astute romancers, like Feliciano de Silva and Marcos Martinez, knew well that the stronger they made the dose the better they pleased their readers, and on principle kept them well plied with rant, bombast, and absurdity, and fooled them to the top of their bent.

But if Cervantes purged his country of sham chivalry, from the bonfire of Don Quixote's books—to borrow the witty image of M. Demogeot—'an unlucky phoenix rose up for the ennui of the 17th century,' the heroic romance, *Polexandre*, *Cléopâtre*, *Cassandre*, *Ibrahim*, *Clélie*, and the rest. Another variety of romance, however, the pastoral, had some share in the genesis of the heroic romance. The Spanish pastorals, supposed by some to have been the descendants of *Daphnis and Chloe*, were in reality, through the *Arcadia* of Sannazaro, the offspring of the Renaissance worship of Virgil, of which were born all the pining shepherds and obdurate shepherdesses that haunt the poetry of the 16th century. For a time they disputed in a feeble way the ascendancy of the chivalry romances, and were threatened with the same fate by Cervantes; but they were left to live out their innocent lives in peace and die at last of their own insipidity. To them, or rather to Montemayor's *Diana*, the first and best of them, we owe one of the patriarchs of the English novel, Sidney's *Arcadia*, and the French owe Honoré d'Urfé's *Astrée*, the precursor of the heroic romances. These were based partly on chivalry, partly on pastoral romance; their strength lay in their combination of sentiment and swagger, the latter borrowed from the chivalry romances, the former from the pastorals; and their one merit, perhaps, was that they provoked some excellent satires, such as Boileau's 'Héros de Roman,' Furetière's *Roman Bourgeois*, Sorel's *Berger Extravagant*, Scarron's *Roman Comique*, and Mrs Lennox's *Female Quixote*.

But a far more important variety of fiction came into existence in Spain in the time, and partly through the influence, of the chivalry romances. These were every day growing wilder and wilder and more and more regardless of all common sense and observance of decent probability, when a little book, called *The Life of Lazarillo de Tormes*, made its appearance. It did not pretend to be a satire or even a protest against the romances in fashion; it merely suggested that a story just as interesting and amusing might be got out of real, everyday life, without magicians, giants, flying dragons, or enchanted palaces, seeing that tastes varied, and that, as Jean Sautrain of Lyons put it in the French translation of 1560, it was not everybody that took delight in reading of heroic deeds. And in fact the *Lazarillo* is studiously unheroic, and the exact opposite of a romance of chivalry. The hero is a beggar boy, or rather a beggar-man's boy; hunger and thrashings are the dragons and giants he has to encounter; his adventures and achievements are cheating and outwitting his masters; the empire of Trebizond that crowns his career is the office of town-crier of Toledo, and the princess that bestows her hand upon him, the doubtful house-keeper of a sly old priest. It was the first genuine attempt at realism in literature, and for the first time in the history of fiction readers found themselves taking pleasure in the creations of the story-teller, not because they were remote from ordinary

experience, but because they were familiar. Finding favour, as a matter of course it had successors. It was followed by the *gusto picaresco* novels, the tales of Spanish rogue and vagabond life, of which *Guzman de Alfarache*, *Marcos de Obregon*, and Quevedo's *Vida del Buscon* are the best-known examples. They took up with this phase of life partly in deference to the precedent of *Lazarillo*, partly because it was a life rich in adventures and incidents, but chiefly because it was a phase of life familiar and real to all readers in Spain in the 17th century. And not in Spain alone, apparently, for the truth of the picaresque novels seems to have been recognised wherever there were readers in Europe; the best of them were translated almost immediately into French, and very soon into English, Italian, German, and Dutch, and, as repeated editions show, took their place everywhere among the acknowledged purveyors of amusement. In Germany, indeed, they may be said to have laid the foundation of the novel in Grimmelshausen's *Simplicissimus*, and in England we need only turn to Defoe for proof of their influence. *Colonel Jack* and *Moll Flanders* are picaresque novels pure and simple, with their parentage stamped upon their features, and there are marks about *Captain Singleton* and *Roxana* that show them to be of the family.

But it was through Le Sage that the picaresque novel came to be influential in shaping modern fiction. Like a keen-eyed horticulturist who detects in some wild plant useful properties that may be indefinitely developed by cultivation, or germs that only need the gardener's skill to expand into endless varieties of form and colour, Le Sage saw the capabilities of this rough growth of Spanish humour, and how its asperities might be removed without impairing its virtues. It may be said it was no great discovery to perceive that disreputable life is not the only one that affords material available for a story of real life, that rascality and roguery are not the only qualities from which amusement may be extracted, and that whatever may be the artistic advantages of a scoundrel, there is on the whole more to be made of a hero who will be accepted by the reader as a man and a brother. But this is only what is said of every discovery as soon as men have come to look upon its consequences as matters of course. Great or small, however, this was Le Sage's discovery, and whether it was of importance or not the modern novel of real life and character will show. It would be difficult, perhaps, to define with precision the extent of Le Sage's share in the formation of this great necessary of present-day existence, but of its reality there can be no question. To take only one illustration out of many—in *David Copperfield* and elsewhere Dickens has left it on record that the favourite stories of his boyhood were *Roderick Random* and *Peregrine Pickle*, a training which shows its fruits in *Pickwick* and all his early works; but if *Gil Blas* was not in the same way Smollett's primer in fiction we have his own word for it that it was the model he set before him when he undertook to 'point out the follies of ordinary life.' This much, at least, cannot be disputed, that he was one of the great masters of the art of story-telling, the first to show an artist's knowledge of the value of details and the right use of realism, and the first to make clear the distinction between the novel and prose fiction in general. *Pantagruel* and *Gulliver's Travels* are not novels, not because the ordinary characteristics of the novel are wanting, but because Rabelais and Swift have merely assumed the disguise of a storyteller for the sake of gaining access to quarters otherwise inaccessible, precisely as Burton put on a pilgrim's dress in order to get into Mecca. In

Don Quixote and *Robinson Crusoe* there may be just as little of the conventional features of the novel, but there is no disguise; they take their places among the novels unchallenged, while the title of *Tristram Shandy* must remain at least questionable, for though it may be called 'The Life and Opinions of Tristram Shandy,' it is in reality 'the freaks and grimaces of the Rev. Laurence Sterne.' Le Sage's theory, so far as we may infer one from his practice, seems to have been that to tell a story is the novelist's business, and to keep to it with singleness of purpose his duty as an artist.

In the foregoing necessarily brief outline of the history of the novel it will be seen that in its growth there has been at work a process very much like that which regulates other growths. One form springs from another, supplants it through being better adapted to surrounding circumstances, and lasts just so long as the adaptation lasts. In the novel, too, as in other cases, forms that have been in this way pushed aside have a tendency to reappear if circumstances favour them. The long-winded sentimental novels of the 18th century were only a reversion of the *romances de longue haleine* of the 17th in a soil that happened to suit them; and in the novels of Horace Walpole, Clara Reeve, and Mrs Radcliffe the spirit of the later romances of chivalry asserted itself, just as the spirit of the older and truer chivalry romance found expression in Scott. *Quentin Durward* is a genuine romance of chivalry, modified only by genius and modern influences. In its extraordinary powers of multiplication and variation also the latter-day novel seems to be subject to natural law. The varieties of wild animals and plants are few, and seldom strongly marked; but no sooner does man for his pleasure or comfort appropriate any living thing, dog or pig, rose or cabbage, than it acquires a variability and fertility apparently limitless. Thus it has fared with the novel ever since Le Sage undertook the domestication of an adaptable species. Having become not merely a source of amusement, but a necessary adjunct of modern life, it now rivals the rabbit in fecundity, and runs into varieties more widely different than greyhound, bulldog, and toy-terrier. This luxuriance of growth, however, cannot be regarded with unmixed satisfaction. It would be no small evil if the novel from an honoured branch of literature were to degenerate into a manufacture.

November (Lat. *novem*, 'nine') was among the Romans the ninth month of the year, and contained 30 days. It subsequently was made to contain only 29, but Julius Caesar gave it 31; and in the reign of Augustus the number was restored to 30, which number it has since retained. Its

festivals are All Saints (1), St Hubert (3), St Martin (11), St Catharine (25), and St Andrew (30).

Novgorod ('new town'), a famous city of Russia, on the Volkhof, near where it issues from Lake Ilmen, 110 miles SSE. of St Petersburg by rail. It is the cradle of Russian history. In 864, according to tradition, Rurik was invited hither by the neighbouring tribes, and from him begins the history of the country and the line of its sovereigns. As early as the 12th century it had important connection with the Hanse cities, and it became the market of north-east Europe. During the time of its prosperity the town was called Novgorod the Great, and had 400,000 inhabitants, and extended its sway to the White Sea and the river Petchora. Its government was a sort of republic. The greatness of Novgorod provoked the jealousy of the princes of Moscow, and in 1471 the tsar Ivan III. nearly destroyed the town, bereft it of its liberties, and exiled the most influential citizens; and when Archangel was opened for English trading-vessels, but especially after the foundation of St Petersburg, its trade fell away, and the town rapidly declined, till now it is but the shadow of its former self. Of the existing ancient buildings the most remarkable are the church of St Sophia, founded in the 11th century, and built on the model of St Sophia at Constantinople, possessing some remarkable paintings and tombs; several others of more than thirty churches; and wall surrounding the Kreml. Pop. 26,000.

Novi, a town of Italy, 30 miles NW. of Genoa by rail; pop. 20,000. Here in 1799 the French were defeated (15th August) and victorious (6th November).

Novipazar, a town of Yugoslavia, on the Raska, an affluent of the Morava, 120 miles SE. of Sarajevo; pop. 11,000. The sanjak of Novipazar, mountainous and barren, but strategically important, was occupied by Austria-Hungary in 1879-1908, but the civil administration reserved to the Porte. After the war of 1912-13 it was divided between Serbia and Montenegro.

Novi Sad, Serbian name of Neusatz (q.v.).

Novorossisk, a fortified port on the Black Sea, to the SE. of Anapa in Russian Caucasia, with trade in corn, cement, and petroleum; pop. 50,000.

Novotcherkask, a town of southern Russia, on the Aksai, a tributary of the Don, 40 miles from the Sea of Azov, was capital of the Don Cossacks country; pop. 60,000, who carry on agriculture, cattle-breeding, fishing, wine-growing, and the making of candles and bricks.

Nowogeorgiewsk, a Polish fortress on the Vistula, 20 miles NW. of Warsaw.

Nowy Sącz. See SANDEC (NEU).

Noyades. See CARRIER (JEAN).

Noyau. See LIQUEUR.

Noyes, ALFRED (b. 1880), a fluent poet of wide appeal, published *The Loom of Years* in 1902, *The Flower of Old Japan* (a dainty verse allegory, 1903), *Drake* (blank-verse epic in 12 books, 1908), and other verse, largely heroic (*Collected Poems*, 3 vols. 1910-20), besides plays, short stories, essays, and *William Morris* in the 'Men of Letters' series. *The Torchbearers* (1922 *et seq.*) is an epic trilogy on the progress of science.

Noyes, J. HUMPHREY. See PERFECTIONISTS.

Noyon, a town in the French department of Oise, 67 miles NNE. of Paris by rail. It has a fine cathedral in the Transition style of the 12th century, an hôtel-de-ville (1485-1523), and a former episcopal palace. Pop. 7000. The *Noviodunum* of Caesar, Noyon was a residence of Charlemagne and Hugo Capet, and the birthplace of Calvin.

Town and cathedral suffered severely in the Great War (q.v.).

Nubia is a comparatively modern name for a large region of Africa, under the Pharaohs called Kush, later a portion of Ethiopia (q.v.), and now mostly included in Anglo-Egyptian Sudan. It extends on both sides of the Nile from Egypt to Abyssinia, touching the Red Sea on the east and the desert on the west. The pre-dynastic culture may have come to Egypt through Nubia. Later the tide of civilisation ran the other way, though under the twelfth dynasty we see signs of Nubian influence in Egypt (see GALLAS). For later history see ETHIOPIA, EGYPT, SUDAN; also MEROE. At present the country is occupied by races belonging to several different stocks, much mixed. The chief elements are Arab, more or less mixed with Nilotic and Negro blood, mainly in Upper Nubia; Ababdeh and Bisharin between the Nile and the Red Sea; and Nubas and Barabira in Lower Nubia, on and near the Nile between Assuan and Dongola. The Semitic Arabs are comparatively recent intruders to this region. They entered Nubia after occupying Egypt in the 7th century, but were resisted by the Christian Dongolawi kings till the 14th century, when the Arabs, assisted by a large contingent of Bosnians, became masters of the land. Both in its lower and upper sections Nubia is for the most part an expanse of steppes or rocky desert, with patches where grass sometimes grows, and ravines in which moisture enough is found to keep alive a few mimosas or palms, and to raise pasture for gazelles and camels. There are also wells and small oases here and there, as on the chief caravan routes. The great 'Nubian Desert' lies east of the Nile, opposite the great western bend of the river. Below Khartum rain is almost unknown; the climate is accordingly excessively hot and dry, and, except in the river-ports after the fall of the Nile, is very healthy. The only exception to the general aridity is the narrow strip of country on both sides of the Nile, which nowhere exceeds four miles in breadth, and in many places is only a quarter of a mile wide. The most fertile part is near Dongola. A mountain barrier bounds the valley on both sides of the Nile, and consists of granite and sandstone.

Nuble, an inland province of Chile. Capital, Chillán (q.v.).

Nucellus. See OVULE.

Nucleus. See CELL.

Nudibranchiata. See GASTEROPODA.

Nuevo León, a northern state of Mexico, of which Monterrey (q.v.) is the capital.

Nuggets. See GOLD.

Nukha, a town of the republic of Azerbaijan; it is on the southern slope of Caucasus, and 120 miles E. of Tiflis; pop. 50,000.

Nullification, in the history of the United States, refers especially to the action of the legislature of South Carolina in 1832, declaring certain acts of congress unconstitutional and therefore null and void. In 1828 congress passed what became known as the 'tariff of abominations,' which discriminated unfairly against the people of the southern states. There cotton was the staple product, and any step tending to impose restrictions on the commercial intercourse with Europe, where its principal markets lay, was bitterly opposed; whereas in the north, with its manufacturing interests, a protectionist policy had steadily grown in favour. In 1832 congress readjusted the tariff, modifying some of the objectionable features, but still leaving the southerners unjustly treated. In November a state convention in South Carolina passed an ordinance nullifying the tariff of 1828 and 1832, and declaring their right and intention,

in the event of any attempt at coercion, to withdraw from the Union and organise a separate government. In December President Jackson (q.v.) issued a vigorous proclamation against the ordinance, and the governor of South Carolina replied with a counter-proclamation, and volunteers, in addition to the state militia, were organised to resist the national government. But in February 1833 Clay, the 'great pacificator,' introduced a Compromise Bill, providing for the gradual reduction by the year 1842 of all higher duties to 20 per cent.; congress passed this on March 2, and on March 15 the South Carolina convention repealed the ordinance of nullification and secession. See CALHOUN; and for the whole question out of which this movement grew, see STATES' RIGHTS.

Numantia, the chief town of the Celtiberian people called Arevaci, in Hispania Tarraconensis, was situated on a steep hill on the Durus (Douro), in the neighbourhood of the present Soria in Old Castile. The site is probably marked by the present Puente de Guaray. Numantia is celebrated for the heroic resistance which it made to the Romans. After a siege of fifteen months, in the course of which famine and the sword had left alive very few of its 8000 brave defenders, it was taken and destroyed by Scipio the younger, 134 B.C. Scipio's army numbered no fewer than 60,000 men.

Numa Pompilius, in the legendary history of Rome, its second king, the successor of Romulus. He was a native of Cures in the Sabine country, and was universally revered for his wisdom and piety. Unanimously elected king by the Roman people, he soon justified by his conduct the wisdom of their choice. After dividing the lands which Romulus had conquered, he proceeded, with the assistance of the nymph Egeria, who gave him interviews in a grove near the city, to draw up religious institutions for his subjects, and thus stands out in the primitive legend as the author of the Roman ceremonial law. His reign lasted for thirty-nine years, and was a golden age of peace and happiness.

Numbers. See PENTATEUCH, BIBLE, APOCALYPTIC NUMBER.

Numbers, THEORY OF, the most subtle and intricate, and at the same time one of the most extensive branches of mathematical analysis. It treats primarily of the forms of numbers, and of the properties at once deducible from these forms; but its principal field is the theory of equations, in as far as equations are soluble in whole numbers or rational fractions, and more particularly that branch known as Indeterminate Equations. Closely allied to this branch are those problems which are usually grouped under the Diophantine Analysis (see DIOPHANTUS), a class of problems alike interesting and difficult, of which the following are examples: (1) *Find two numbers the sum of whose squares shall be a square number*; a condition satisfied by 5 and 12, 8 and 15, 9 and 40, &c. (2) *Find three square numbers in arithmetical progression*: Answer, 1, 25, and 49; 4, 100, 196, &c.

Forms of Numbers are certain algebraic formulas, which, by assigning to the letters successive numerical values from 0 upwards, are capable of producing all numbers without exception—e.g. by giving to m the successive values 0, 1, 2, 3, &c., in any of the following groups of formulas, $2m$, $2m+1$; $3m$, $3m+1$, $3m+2$; $4m$, $4m+1$, $4m+2$, $4m+3$, we can produce the natural series of numbers. These formulas are based on the self-evident principle that the remainder after division is less than the divisor, and that consequently every number can be represented in the form of the product of two factors + a number less than the smaller factor.

By means of these formulas many properties of numbers can be demonstrated without difficulty. To give a few examples. (1) *The product of two consecutive numbers is divisible by 2*: Let $2m$ be one number, then the other is either $2m+1$ or $2m-1$, and the product $2m(2m \pm 1)$ contains 2 as a factor, and is thus divisible by 2. (2) *The product of three consecutive numbers is divisible by 6*: Let $3m$ be one of the numbers (as in every triad of consecutive numbers one must be a multiple of 3), then the others are either $3m-2$, $3m-1$; $3m-1$, $3m+1$; or $3m+1$, $3m+2$. In the first and third cases the proposition is manifest, as $(3m-2)(3m-1)$ and $(3m+1)(3m+2)$ are each divisible by 2, and therefore their product into $3m$ is divisible by 6 (= 1.2.3). In the second case the product is $3m(3m-1)(3m+1)$, or $3m(9m^2-1)$, where 3 is a factor, and it is necessary to show that $m(9m^2-1)$ is divisible by 2: if m be even, the thing is proved; but if odd, then m^2 is odd, $9m^2$ is odd, and $9m^2-1$ is even; hence in this case also the proposition is true. It can similarly be proved that the product of four consecutive numbers is divisible by 24 (= 1.2.3.4), of five consecutive numbers by 120 (= 1.2.3.4.5), and so on generally. These propositions form the basis for proof of many properties of numbers, such as that the difference of the squares of any two odd numbers is divisible by 8. The difference between a number and its cube is the product of three consecutive numbers, and is consequently (see above) always divisible by 6. Any prime number which, when divided by 4, leaves a remainder unity, is the sum of two square numbers: thus, $41 = 25 + 16 = 5^2 + 4^2$, $233 = 169 + 64 = 13^2 + 8^2$, &c.

Besides these there are a great many interesting properties of numbers which defy classification; such as that the sum of the odd numbers beginning with unity is a square number (the square of the number of terms added)—i.e. $1 + 3 + 5 = 9 = 3^2$, $1 + 3 + 5 + 7 + 9 = 25 = 5^2$, &c.; and the sum of the cubes of the natural numbers is the square of the sum of the numbers—i.e. $1^3 + 2^3 + 3^3 = 1 + 8 + 27 = 36 = (1 + 2 + 3)^2$, $1^3 + 2^3 + 3^3 + 4^3 = 100 = (1 + 2 + 3 + 4)^2$, &c.

Numbers are divided into *prime* and *composite*—prime numbers being those which contain no factor greater than unity, composite numbers those which are the product of two (not reckoning unity) or more factors. The number of primes is unlimited, and so consequently are the others. The product of any number of consecutive numbers is even, as also are the squares of all even numbers; while the product of two odd numbers, or the squares of odd numbers, are odd. Every composite number can be put under the form of a product of powers of numbers; thus, $144 = 2^4 \times 3^2$, or generally, $n = a^p \cdot b^q \cdot c^r$, where a , b , and c are prime numbers, and the number of the divisors of such a composite number is equal to the product $(p+1)(q+1)(r+1)$, unity and the number itself being included. In the case of 144 the number of divisors would be $(4+1)(2+1)$, or 5×3 , or 15, which we find by trial to be the case. *Perfect numbers* are those which are equal to the sum of their divisors (the number itself being of course excepted); thus, $6 = 1 + 2 + 3$, $28 = 1 + 2 + 4 + 7 + 14$, and 496 are perfect numbers. *Amicable numbers* are pairs of numbers, either one of the pair being equal to the sum of the divisors of the other; thus, 220 ($= 1 + 2 + 4 + 5 + 10 + 11 + 20 + 22 + 44 + 55 + 110 = 284$) and 284 ($= 1 + 2 + 4 + 71 + 142 = 220$) are amicable numbers. For other series of numbers, see FIGURATE NUMBERS.

The most ancient writer on the theory of numbers was Diophantus, who flourished in the 3d century, and the subject received no further development till the time of Vieta and Fermat (q.v.), who

greatly extended it. Euler next added his quota, and was followed by Lagrange, Legendre, and Gauss, who in turn successfully applied themselves to the study of numbers, and brought the theory to its present state. Cauchy, Libri, and Gill (in America) have also devoted themselves to it with success.

See Barlow's *Theory of Numbers* (1811); Legendre's *Essai sur la Théorie des Nombres* (3d ed. Paris, 1830); and Gauss's *Disquisitiones Arithmeticae* (1801; new ed. 1860; Fr. trans. 1807); H. J. S. Smith, in *Brit. Ass. Reports* (1859-65); Cayley, in *Brit. Ass. Reports* (1875); L. E. Dickson, *History of the Theory of Numbers* (1923).

Numerals. The denary system of notation is due to the fact that we have ten fingers. The rude method of finger-counting has been developed into a highly-complicated system of reckoning, still in use in eastern Europe by pedlars; various positions and arrangements of the ten digits allowing of reckoning as high as 10,000. For permanent purposes a system of single strokes is the most obvious method; and series of strokes as high as four or five are found in various countries in old inscriptions. But strokes, when numerous, are inconvenient and confusing; hence additional symbols are found to make their appearance for 5, 10, 100, and 1000. For the Babylonian system see SCALES OF NOTATION. The Egyptian scheme is illustrated at HIEROGLYPHICS; and from these hieroglyphs were derived the Phœnician, Palmyrene, and Syriac numerals.

After alphabetic writing was in use, the alphabetic signs obviously lent themselves to employment as numerals—either following the order of the letters, each having a successively greater value than its predecessor; or the initial letter of the word for the several numbers might be used. Thus, according to the latter method, the Greek inscriptions used I for 1, II (ἑντε) for 5, Δ (τέκα) for 10, H (the old sign for the rough breathing in ἑκατον) for 100, X (ἑκατοί) for 1000, and M (ἑκατοί) for 10,000. Then a II with a Δ inscribed in it stood for 50 (5 × 10), and with H inscribed (5 × 100) for 500. In this connection the capitals or uncials were used of course. (For the derivation of letters from numerals see OGAM.) Otherwise, following simply the order of the letters, the twenty-four letters of the Ionic alphabet were used for the numbers 1 to 24; the books of the *Iliad*, for example, are often thus numbered. But a more ingenious method was soon adopted by the Greeks, as also by the Hebrews. The alphabet (cursive) was divided into three groups, of which the first did duty for the units, the second for the tens, the next for hundreds. The Hebrew square character had twenty-two distinct letters, and double forms for five of them, so that three groups, each of nine characters, were available. The Greek alphabet, as ultimately arranged, had twenty-four letters; the three additional signs required to make up three nines were obtained by keeping two old letters for ς (see DIGAMMA) for 6, and 5 or 4 (koph) for 90, and adding the superfluous sibilant ϑ (sampi) for 900. Then α to θ were 1 to 9; from ι to κoph were 10 to 90; ρ to sampi were 100 to 900. The thousands were made by subscribing an ι beneath the units; thus α was 1000. Sometimes a sort of algebraic method was employed for larger numbers; βM = (2 × 10,000) 20,000.

The cumbersome Roman method of using the capitals is familiar enough to ourselves yet. The C has been understood to be the initial of *centum*, and M of *mille*. But some (as Taylor) have contended that the Latins, when they dropped the Greek *phi*, *chi*, and *theta* as phonetic signs, retained them as numerals, with arbitrary values. In this case the C would be originally Θ, assimilated to C, because C was the initial of *centum*. The old ⊕, used for

1000, came to be written CIO, afterwards confounded with ∩ or ∪, the initial of *mille*. The L would be a derivative from an old Chalcidian form of *chi*, inscribed for lapidary purposes ⊥, and then simplified. Those who do not accept the theory of the dropped Greek letters suppose that M is from a circle with a vertical stroke, the C a circle with a horizontal stroke or a cross, ⊕. The X, V, and L might all come from this letter. In any case, X is twice V (whether or not the latter originated in the hand held with the thumb to one side and the other fingers together); and D (for 500) or IO is half CIO.

It is doubtful how far the Abacus (q.v.) has to do with the development of the system of numerals, in which the value of the cipher depends on its position. There were abacus boards so arranged that the first column meant units, the second tens, the third hundreds, the fourth thousands. A method of writing numbers derived from this was actually used in Europe in the middle ages; we show the columnar arrangement simplifying the reading in the several cases, 654, 650, 604, 54.

In the decimal scheme of figures as now used by us, the nine numerals with the zero, which enables the value of the position to be secured without abacus or columnar arrangement, are known as the Arabic numerals, but are unquestionably of Indian origin. From India they were apparently brought to Bagdad after the middle of the 8th century, and their value and use was set forth early next century by the Arab mathematician Abu Ja'far Mohammed Ben Musa, or Al-Kharizmi ('native of Kharizm'—Khiva); whence the system came to be known in Europe, where it became familiar in the 12th century as *Algorism* (erroneously *Algorithm*). The earliest European forms of these characters are found in MSS. of the 12th century; by the 14th they were practically of the same shape as now. The 12th century numerals are evidently forms of the Gobar or western Arabic numerals used in

a, Indian, 10th century; b, Gobar, 10th century; c, European, 12th century.

Persia in the 10th century. These can be traced to the contemporary Indian Devanagari numerals, which again are as certainly based on an old series of characters used in cave-inscriptions in the 1st and 2d centuries. These Canon Taylor contended are (mainly, at least) degraded forms of the Indo-Bactrian alphabet. On the other hand, comparison of archaic Indian and Chinese numerals suggests derivation from a stroke system. In early Indian cave inscriptions one, two, and three resemble the Roman numerals, but the strokes are horizontal instead of vertical. Four and five may be different views of the hand (five showing the thumb). The others are explained as combinations. The modern arithmetic was not practised in England till about the middle of the 16th century, and for a long time after its introduction was taught only in the universities.

Geschichte unsrer Zahlzeichen (1875); G. F. Hill, *The Development of Arabic Numerals in Europe* (1915). See also DECIMAL SYSTEM, SCALES of NOTATION, SHEEP-SCORING NUMERALS.

Numidia (Gr. *Nomadia*, 'land of Nomads'), the name given by the Romans to a part of the north coast of Africa, corresponding to some extent with the modern Algiers, and lying between Mauritania and the Roman province of Africa; on the south it reached to the chains of Mount Atlas. The inhabitants of Numidia, as of Mauritania, belonged to the race from which the modern Berbers are descended. They were a warlike race, and excelled as horsemen, but were proverbially faithless and unscrupulous. Of their tribes the *Massyli* in the east and the *Massesyli* in the west were the most powerful. In the grand struggle between the Carthaginians and the Romans they at first fought on the side of the former, but subsequently the king of the Eastern Numidians, Massinissa, joined the Romans, and rendered them effectual service in the war with Hannibal. Favoured by the conquerors, he united all Numidia under his sway. Of his successors in this kingdom Jugurtha and Juba are the most famous. After the victory of Cæsar over Juba I. in the African war Numidia became a Roman province (46 B.C.); but Augustus afterwards gave the western part, with Mauritania, to Juba II., and the name Numidia became limited to the eastern part. Among important places were Hippo Regius, Zama, and Cirta (the residence of the Numidian kings), afterwards called Constantina, a name still preserved in Constantine. For the modern history of Numidia, see ALGIERS.

Numismatics (Gr. *nomisma*, from *nomos*, 'law,' 'a legally current coin') is the science which embraces the study of the current coins of all nations. In the wider, though less accurate, acceptance of the term it includes also that of medals, both artistic and historical. The various branches of numismatics are (1) Greek, Phœnician, &c.; (2) Roman and Byzantine; (3) Mediæval and Modern; and (4) Oriental. The chief value of numismatics consists in the light which coins throw upon history. The secondary importance of the science is purely artistic. The study of coins is also of great use in elucidating the mythology of the ancients, in fixing the chronology of the different systems of alphabetical writing (Palæography), and in indicating the origin and gradual extension over the civilised world of the principal systems of weighing the precious metals (Metrology). Historically, coins are of the utmost importance as being contemporary and authentic documents furnishing us with in many cases the only means of ascertaining the names of obscure cities and peoples, together with the chronological succession of their kings, tyrants, or chief-magistrates. Artistically, they faithfully record the successive phases of art from its earliest beginnings to its culminating point, and through all the stages of its decline, subsequent temporary revival, and second decadence, to the present day.

I. *Greek Coins*.—The use of the precious metals as mediums of exchange may be traced back to the remotest ages of which we possess any historical accounts. Thus, for instance, we read that Abraham was 'very rich in cattle, in silver, and in gold' (Gen. xiii. 2; xxiv. 35), and in the account of his purchase of the cave of Machpelah (Gen. xxiii. 16) it is stated that 'Abraham weighed to Ephron four hundred shekels of silver current with the merchant.' This use of gold and silver as uncoined money, weighed in the balance, must, however, be carefully distinguished from its use as 'coin,' a word which implies that the ingot or piece

of metal is impressed with an official device, mark, or 'type,' serving the purpose of a guarantee of just weight and value. 'So far as we have any knowledge,' says Herodotus (i. 94), 'the Lydians were the first nation to introduce the use of gold and silver coin.' The best authenticated Greek tradition (Herodotus, i. 94) attributed the invention of coinage to the Lydians; but although the metal of which the earliest coins were made doubtless came from Lydia, it is probable that the invention was due to some of the Greek cities on the Ionian coast, such as Miletus. The most primitive specimens of the art, which may go back to about 700 B.C., if not earlier, are bean-shaped lumps of the native Lydian gold ore, which contained a large admixture of silver, and went by the name of *electrum* or pale gold. The face or *obverse* of the coin bears normally some kind of design (though on the very earliest pieces it is undecorated), and the *reverse* consists merely of the impress of the rude unengraved punch or nail-head which served to keep the ingot in its place while it was being struck. The ingot was placed on an anvil, into which had been let a die engraved in intaglio with the design which it was desired to impress on the obverse; the punch was placed on the top of the ingot, and was held in position by tongs, while the moneyer struck it with successive blows of a heavy sledge-hammer until the impressions of the engraved die on the obverse and of the square nail-head on the reverse were brought into sufficient relief and intaglio respectively. The design or type was the *signet* of the issuing authority (personal ruler or city-state); owing to the intense penetration of Greek life by religion, these signets are more often than not of a sacred character, representing objects or animals consecrated to deities, or the deities themselves.

These one-sided coins with an intaglio or 'incuse' square on the reverse are characteristic of the early stages of the art of coining not only in Asia Minor but in all the Greek cities, for the use of coined money rapidly spread from Ionia over all the coasts and islands of the Ægean Sea. In Greece proper the earliest coins were of silver, and were struck in Ægina in the 7th century B.C. They bear the symbol of a tortoise.

Before the introduction of coinage proper there had been current in Peloponnesus bars or spits (*ὀβελίσκοι*) of iron or bronze, the regulation of which primitive currency, as of the weights and measures of his time, was due to Pheidon, king of Argos, probably about the middle of the 8th century. Such spits have been found in the temple of Hera at Argos, where they were probably dedicated when superseded. From about 700 B.C. onwards the coinage of Greece and of the East may be classified historically in the following eight periods:

(i.) 700–480 B.C.—Period of archaic art, ending with the Persian wars.—The art work on the coins of these two centuries is characterised at first by a rude strength of style, and afterwards by a gradual development into clearly-defined forms, which, however, are always distinguishable by their angularity and stiffness from the freer work of later times. Thus, for instance, the eye of the human face is always drawn, even when in profile, as if seen from the front, both corners being visible, while the mouth wears a fixed and formal smile, due to an attempt to give liveliness of expression. Towards the end of the archaic period a type in relief begins to appear within the incuse square of the reverses. The coins which circulated most widely were, in silver, those of Ægina with the tortoise above referred to; the Corinthian coins with the Pegasus; the tetradrachms of Athens, first introduced by Peisistratus about 550 B.C., obverse, head of Athena, reverse, owl, the sacred bird of that goddess; and, in gold, the famous

Darics, on which the Persian king is represented as a kneeling archer. In the west the chief coins were those of the Greek colonies in southern Italy, Sybaris, Croton, Tarentum, &c., which differ from those of Greece proper in having the figures on the reverse in intaglio instead of in relief.

(ii.) 480-415 B.C.—Period of transitional and early fine art, to the end of the Athenian supremacy.—The coins of this period are characterised by a great advance in the technical skill with which the dies were engraved. The name of the city or of the chief-magistrate now occurs frequently on the reverse, usually in an abbreviated form.

In Asia Minor the chief coinage of this period is the electrum currency of the flourishing commercial city of Cyzicus on the Propontis, so often alluded to under the name of 'Cyzicene staters' by Xenophon and other historians. In Greece proper the Athenian money was still the chief, though by no means the only medium of exchange, and in the West the Corinthian staters, with the figure of Pegasus on the obverse, had a wide circulation. In Sicily Syracuse affords a larger variety of types than any other Greek city, though the finest specimens of the Syracusan monetary art fall into the next period.

(iii.) 415-336 B.C.—Period of finest art, age of the Spartan and Theban supremacies, and of Philip of Macedon.—The art of die-engraving attained in this period a higher point of excellence than it has ever since reached. The coin-types are remarkable for sculptural reserve, intensity of action, or rich and varied ornamentation, according to the requirements of the subject represented. These

Medallion of Syracuse.

are most frequently ideal heads of divinities on the obverses, and mythological figures on the reverses, or agonistic types referring to the local games and religious festivals, such as the victorious quadrigæ on the famous Syracusan medallions (first issued after the failure of the Athenian expedition against Syracuse), which are generally recognised as the finest coins that have ever been struck. In this age the practice of coining money had become universal; the number of mints throughout the civilised world was enormous, every little town striking its own 'autonomous' silver or bronze, and, in some cases, gold currency. In European Greece the gold staters of Philip of Macedon obtained a wide circulation, and his conquests in Greece gradually put an end to the independent issues in that country. Philip's gold was imitated, with ever-increasing debasement of style, by the Celtic tribes of Central Europe and Gaul, and from these imitations were ultimately derived the first primitive gold coins of the Britons.

(iv.) 336-280 B.C.—Period of later fine art; age of Alexander the Great and the Diadochi, characterised by the introduction of the portrait of the reigning monarch in place of the head of the divinity on the obverse.—Before Alexander's time no tyrant, however despotic, had ever ventured to

place his own head upon the coinage of the state. The regal money of Alexander and his successors now gradually superseded the autonomous coinage of the smaller Greek states, except in the west, which was beyond the sphere of Alexander's conquests, and where the cities of Italy and Sicily continued to strike gold and silver until they were in turn brought under subjection by the growing power of Rome (see below).

(v.-vii.) 280 B.C. to the Christian era.—Periods of early and later decline; age of the Epigoni, the Attalids, and of Mithradates the Great.—The silver and gold coinage during these three centuries is almost exclusively regal, and presents us with a remarkable series of lifelike portraits of the long succession of the Seleucid kings of Syria, of the Ptolemies of Egypt, of the kings of Macedon, of Pontus and Bithynia, of the Attalids of Pergamum, and of the successors of Alexander in northern India, many of whom are known to us only from their coins. The chief characteristic of the art of numismatic portraiture, which attained its highest perfection about 250 B.C., is its realism, which is carried in some cases almost to the verge of brutality, as, for instance, on the tetradrachms of some of the kings of Pontus, the ancestors of Mithradates the Great. Among the latest portraits on Greek coins is that of the famous Cleopatra on a coin of Ascalon. She is represented with little of the seductive beauty which we should expect to find on the coins of this fascinating princess. Among the non-regal coins of the 2d century B.C. the large tetradrachms of some of the Greek cities of the western coast of Asia Minor, which re-

gained their freedom after the defeat of Antiochus the Great by the Romans, 190 B.C., are worthy of note; those of Cyme, Myrina, Smyrna, and Magnesia being especially remarkable. Local imitations of the silver coinage of Alexander the Great are also very plentiful. Throughout the greater part of this period Athens continued to coin very plentifully her tetradrachms with the helmeted head of the chryselephantine statue of Athena Parthenos by Phidias on the obverse. These coins formed the chief currency for the trade between Europe and the East.

(viii.) From the Christian era to the reign of the Emperor Gallienus.—During this period of nearly three centuries the Romans per-

mitted the Greek cities in the eastern half of the empire to strike bronze money for local use. It is known to collectors as the 'Greek imperial' coinage. Artistically it is quite without interest, but archæologically it is perhaps more important than the matchless silver and gold currency of the free and independent cities of more ancient times. The Greek imperial coins illustrate the local festivals, religious rites, and municipal institutions which prevailed in the out-lying provinces of the Roman empire, and are also of value as recording the names of the successive chief-magistrates and high officials of the various cities, who appear to have been responsible for the coinage in each locality.

II. *Roman and Byzantine Coins.*—The Romans for the first four centuries of their history had no regular coinage, the chief medium of exchange being bronze, circulating by weight, *aes rude*, in lumps of irregular form. It was late in the 4th century B.C. that the pound-weight of bronze (12 oz.) was first cast into large unwieldy pieces of circular shape, *aes grave*, having on the obverse a head of Janus, and on the reverse the prow of a galley. This was the Libral As; and its divisions were the Semis (6 oz.), the Triens (4 oz.), the Quadrans (3 oz.), the Sextans (2 oz.), and the Uncia (1 oz.), each of which bore a dis-

linet type and mark of value. Somewhat later (perhaps during the Pyrrhic War) silver Roman coins were issued in Campania. As time went on the As was gradually reduced in weight until (circa 269 B.C.) it stood at no more than 2 oz. This reduction is explained by the fact that bronze, originally in Italy the standard metal, was gradually superseded in that respect by the silver money struck at the Capuan mint, so that it was no longer important to maintain the full weight of the bronze money. In 268 B.C. the Roman mint issued for the first time a silver coin, the Denarius, equivalent to ten asses. The fractions of the silver piece were the Quinarius (five asses) and the Sestertius (two and a half asses). In 217 B.C. the weight of the as was further legally reduced to 1 oz. (uncial reduction), and again in 89 B.C. to half an ounce (semuncial reduction). The types of the silver coins, at first constant and uniform, were subsequently varied according to the pleasure of the *triumviri monetales*, as the officers were called who were entrusted with the supervision of the coinage. The long series of the Republican silver money, which extends from 268 B.C. to Imperial times, is sometimes incorrectly known as the Consular or Family series, because the types usually allude to events connected with the family history of the *triumviri monetales*. The Imperial series commenced in the reign of Augustus, who reserved for himself all rights connected with the coinage of gold and silver, though leaving to the senate the privilege of striking bronze at the Roman mint, whose issues were accordingly henceforth distinguished by the letters S.C. (*Senatus Consulto*). Under Augustus, from 15 B.C., and Tiberius gold and silver were issued not from Rome but from Lyons. Supplementary mints were established at Alexandria and elsewhere. All coins now bore the portrait of the reigning emperor, or of some member of the imperial family, and on the reverse, for the most part, allegorical personifications, representations of historical events, architectural monuments, or public buildings. Their inscriptions often furnish us with the exact date of issue. The chief denominations were, in gold, the aureus; in silver, the denarius; and in brass or copper, the sestertius, tarified at four asses; the dupondius, two asses; and the as and semis, sometimes also the quadrans. The large brass coins from Augustus to Commodus supply us with a magnificent series of imperial portraits, but from Septimius Severus onwards there is a rapid deterioration both in art and workmanship. From the reign of Caracalla to that of Diocletian the utmost disorder prevailed in the coinage, each successive emperor debasing it more and more, until the so-called silver denarius became merely a copper coin washed with tin. In 296 A.D. Diocletian entirely reformed the currency, which was again modified by Constantine, who reduced the weight of the aureus from sixty to seventy-two to the pound. The new gold piece was henceforth known as the Solidus, and it maintained its full weight and purity of metal as long as the empire lasted. This coin received in western Europe the name of Bezant or Byzant, from Byzantium or Constantinople, the capital of the eastern empire. The types of the coins of the Christian emperors retained for a time their pagan character, though little by little Christian symbolism crept in, until at length all pagan influence disappeared, and figures of Christ and the Virgin took the place of the allegorical representations of pagan times. The Latin language in the inscriptions on Byzantine coins continued to be used until the middle of the 11th century, when it was finally displaced by the Greek.

III. *Medieval and Modern Coins*.—The coinage of western Europe, down to the time of Charle-

magne, consisted mostly of imitations of the Byzantine coins. That emperor (circa 768 A.D.) introduced a new silver coin called the *new denier*, which soon came into general use.

English.—The *denier* was introduced into England, under the name of the *penny*, by Offa, king of Mercia (757–796), previous to whose time the currency of the Anglo-Saxons had consisted of small gold and silver coins (*sceattas*) and copper coins (*styccas*), which were mainly rude copies of Roman or of Merovingian money. Under the Anglo-Saxon and early Norman kings local mints were established at all the considerable towns in England, and the penny frequently bore on its reverse both the name of the town and of the moneyer by whom it was struck. An attempt to introduce a regular gold currency was made by Henry III., but gold money did not come into general use until the reign of Edward III., who introduced first the florin (6s.), which was at once withdrawn, and then (in 1344) the *noble* (6s. 8d.), with its divisions. This king also was the first to strike in any quantity multiples of the penny, *groats* (4d.) and *half-groats*. Edward IV. added new denominations called the *rose noble* and the *angel*, so called from its type, St Michael slaying the dragon. With the accession of the Tudor dynasty authentic portraits of the reigning sovereign make their first appearance on the coins of the realm, and many new denominations, such as *sovereigns* in gold and *shillings* in silver were added. In the time of Charles I. we note a remarkable improvement in the art of die-engraving, of which the celebrated *Oxford crown* is a good example; on the obverse of which is the king on horseback, with a view of the city of Oxford in the distance. In 1562 the mill and screw were introduced from France for striking coins, in place of the old-fashioned hammer and anvil, but did not come into general use until 1662. On the coins of the Commonwealth the inscriptions are in English instead of Latin, and some of Cromwell's portraits by the famous engraver, Thomas Simon, are worthy of the highest praise. To the series of Charles II. belongs the beautiful *Petition crown*, also by Simon. This coin takes its name from Simon's petition to be reinstated as engraver to the mint, inscribed on the edge: 'Thomas Simon most humbly prays your majesty to compare this, his tryal-piece, with the Dutch, and if more truly drawn and embossed, more gracefully ordered, and more accurately engraved, to relieve him.' The petition was not granted. In Charles II.'s reign the first *guineas* were struck from gold brought from the Guinea Coast, and copper coins, consisting of *halfpennies* and *farthings*, were first regularly established. From this time onwards the English coinage declines very greatly in artistic interest, George IV.'s crown by Pistrucci being perhaps the only modern piece worth noticing. The supposed extreme rarity of Queen Anne's farthings is a myth.

Scottish.—The coinage of Scotland down to the reign of Robert III. followed closely the English types. From this time original designs became more frequent. It reached its highest point of artistic excellence in the reigns of James V. and Mary; the best-known coins of this period are the *bonnet-piece* of the former, representing the king wearing a bonnet, and the *ryal* of the latter, bearing the queen's portrait in profile.

Irish.—The earliest Irish coins were struck by the Danish ruler Sihtric III. (989–1029). They were copied from the pennies of Ethelred II. After this we have no Irish coinage until the partial conquest of the country by Henry II., in whose reign mints were established at Dublin and Waterford, where his son John issued coins as Lord of Ireland. After this the coinage continues, with many gaps,

down to the reign of George IV. Among the more modern Irish coins the gun-metal money of James II. is historically interesting. This was 'money of necessity,' struck after his flight from England. It was decreed in the reign of William and Mary, and redeemed only at metal value.

Western Europe.—The mediæval and modern coinage of the various European states, from the time of the issue of the *denier* by Pépin le Bref (in 757) and of the *new denier* by Charlemagne down to the middle of the 17th century, is of extraordinary historical interest. The Italian coins are artistically superior to the rest, especially in portraiture, where the influence of the Renaissance of art may be clearly traced. An important landmark in the numismatic history of western Europe is the reintroduction of gold money, dating from the first issue of the *florino d'oro* in Florence, 1252. An equally important gold coin, the Venetian *sequin* or *ducat*, was introduced in 1284. The silver *gros* was introduced by St Louis (1226–70). In France the coins of Francis I. and Henry II., and in Germany those of the Emperor Maximilian I., are especially noteworthy. Many of the German *bracteates* (thin pieces struck on one side only) of the 12th–13th century have great interest, and the *thalers*, from the early 16th century onwards, are also of historical value, as their types record the chief events in the history of the cities by which they were struck.

IV. *Oriental Coins.*—Oriental coins fall into three principal divisions: (i.) The coins of India beginning with those of the successors of Alexander the Great in the 3d century B.C. in Bactria and the Punjab, and extending down to recent times. The gold and silver coins of the Pathan kings and of the Mogul emperors may be here particularised, more especially the gold *mohurs* and silver *rupees* of Jehangir with the signs of the zodiac.

(ii.) The coins of the numerous Arab dynasties in Asia, Africa, and Spain consist of *dinars* in gold and *dirhems* in silver. The interest of these Mohammedan issues is purely historical, as they bear no representations of living beings, all such images being forbidden to true believers. Many of these coins possess, however, a beauty of their own as specimens of oriental caligraphy. The inscriptions consist of formulæ of the faith from the Koran, together with the name of Khalif, the place of mintage, and the date of issue. The Kufic coins are the subject of a special article.

(iii.) The coins of China, Japan, and the Far East.—Those of China date from the 7th century B.C., the earliest being in the form of tools, such as spades, knives, &c. In the 1st century B.C. these pieces are replaced by circular discs of brass called *cash*, with a square hole in the centre, a form of coin which has survived until quite recent years. The coins of Japan begin about the 5th century A.D., and are modelled on the later Chinese pattern. Among the more modern Japanese issues are oblong pieces of gold and silver, and large oval plates, called *o-ban* and *ko-ban*, some of which are more than 6 inches in length. Like China, Japan has now adopted a currency modelled on the European pattern.

See Eckhel's *Doctrina Numorum* (1792–98); B. V. Head, *Gold and Silver Coins of the Ancients* (3d ed. 1889) and *Historia Numorum* (2d ed. 1911); G. Macdonald, *Coin Types* (1905), *Evolution of Coinage* (1916), and his *Greek Coins in the Hunterian Museum* (3 vols. 1899–1905); G. F. Hill, *Handbook of Greek and Roman Coins* (1899); Babelon, *Traité des Monnaies grecques et romaines* (1901 et seq.); and the *Catalogues of Greek Coins in the British Museum* (1873 et seq.). On Roman coins the chief works are Mommsen, *Histoire de la Monnaie romaine* (trans. by Blacas, Paris, 1865–75); the *Catalogues of the Roman Republican and Imperial Coins* and of the *Byzantine Coins in the British Museum* (1908

et seq.); Mattingly and Sydenham, *Roman Imperial Coinage* (1923 et seq.). On mediæval, modern, and oriental coins: J. A. Blanchet, *Numismatique du Moyen Âge et Moderne* (1890); A. Engel and R. Serrure, *Traité de Numismatique du Moyen Âge* (1891 et seq.), and *Traité de Numismatique Moderne* (1897–99); Ruding, *Annals of the Coinage of Great Britain* (1840); Hawkins, *Silver Coins of England* (1887); Kenyon, *Gold Coins of England* (1884); the *British Museum Catalogues of Anglo-Saxon Coins and Norman Coins* (1887 et seq.) and *Handbook of Coins of Great Britain, &c.* (1899); E. Burns, *Coinage of Scotland* (1876); the *British Museum Catalogues of Oriental Coins* (1875–90) and of *Indian Coins* (1908 et seq.); O. Codrington, *Manual of Musulman Numismatics*; E. J. Rapson, *Indian Coins*; the *Catalogue of Coins in the India Museum, Calcutta* (1906 et seq.); and *Catalogue of Coins in the Panjab Museum* (1914).

Nummulites, or NUMMULINA ('money-fossils'), a genus of fossil foraminifera, the shells of which form immense masses of rock of Eocene age. They are circular bodies of a lenticular shape, varying in magnitude from the merest point to the size of a florin or larger. The shell is composed of a series of small chambers arranged in a concentric manner. The growth of the shell does not take place only around the circumference, but each whorl invests all the preceding whorls, so as to form a new layer over the entire surface of the disc, thus adding to the thickness as well as the breadth, and giving the fossil its lenticular

Nummulites.

form. A thin intervening space separates each layer from the one which it covers, and this space at the margin swells out to form the chamber. All the internal cavities, however, seem to have

been occupied with the living sarcodæ, and an intimate connection was maintained between them by means of innumerable parallel tubuli, which everywhere pass from one surface to another, and which permitted the passage of the sarcodæ as freely as do the minute pores or foramina of the living foraminifera. The name is given to them from their resemblance to coins. The genus appears first in the Carboniferous system, where it is represented by one small form. Several species are also met with in Jurassic and Cretaceous rocks, but the genus reached its maximum in Eocene times. It is represented at present by only a few small forms.

NUMMULITE LIMESTONE, an important member of the Eocene system of southern Europe, &c., consists of a limestone composed of nummulites held together by a matrix formed of the comminuted particles of their shells, and of smaller foraminifera. It attains a thickness of several thousand feet, and has been traced over a vast area. It occurs on both sides of the Mediterranean basin, in Spain and in Morocco. It enters largely into the composition of the Apennines, the Alps, the Carpathians, and the Balkans; it extends through Greece, Egypt, and Asia Minor, and thence through Persia and the Himalayas to the coasts of China and Japan.

Nun (O.E. *nunna*; Low Lat. *nunna* or *nonna*, 'mother'; Gr. *nannē*, *nenna*, 'aunt'; Sansk. *nandā*, a familiar word for 'mother,' corresponding to Sansk. *tatā*, 'father'), a member of a religious order of women. The general characteristics of the religious orders will be found under the head MONACHISM (q.v.) and under those of the several orders. Of arrangements peculiar to the religious

orders of women the most striking perhaps is the strictness in the regularly authorised orders of nuns taking solemn vows, nuns of the 'cloister,' or enclosure, which no extern is ever permitted to enter, and beyond which the nuns are never permitted to pass, without express leave of the bishop. The superiors of convents of nuns are called by the names Abbess, Prioress, and, in general, Mother Superior. They are, ordinarily speaking, elected by chapters of their own body, with the approval of the bishop, unless the convent be one of the class called exempt houses, which are immediately subject to the authority of the holy see. The ceremony of the solemn blessing or inauguration of the abbess is reserved to the bishop, or to a priest delegated by the bishop. The authority of the abbess over her nuns is very comprehensive, but a precise line is drawn between her powers and those of the priestly office, from which she is strictly debarred. The name of nun is given in general to the sisters of all religious congregations of females who live in retirement and are bound by rule; but it is primitively and properly applicable only to sisters of the religious orders strictly so called. In most cases, soon after the foundation of the orders for men corresponding orders have been established for women. The usages as to diet, fasting, clothing, &c. are very various in the different communities. The veil of reception given to a postulant at the beginning of her novitiate is white; that of profession, given at the end of it, is black in some orders, white in others.

Nunc Dimittis, the name given to the canticle of Simeon (Luke, ii. 29-32), which forms part of the compline office of the Roman Breviary, and is retained in the evening service of the Anglican Church when it follows the second lesson.

Nuncio. See LEGATE.

Nuncomar. See HASTINGS (WARREN).

Nundydroog (*Nandidrug*), a fortified hill in Mysore, 31 miles N. of Bangalore, and 4810 feet above the sea. The extensive fortifications on the plateau-summit were erected by Hyder Ali and Tippoo Saib, and were stormed by a British force in 1791. The place is now used as a health-resort by Europeans from Bangalore.

Nuneaton, a municipal borough (1909) in the Warwickshire coalfield, 9 miles N. of Coventry. Industries besides coal-mining are the ancient ones of worsted, cotton, and woollen spinning and weaving, iron and sheet metal, hats, artificial silk, and elastic webbing. To the 'Etone' ('water town'), of Domesday the prefix 'Nun' was added when a Benedictine nunnery, of which some ruins remain, was founded in Stephen's time. There is a good Gothic church (mostly 14th century). John Ryder, archbishop of Tuam, was a native (1697); and George Eliot was born at Arbury Farm, just outside Nuneaton (the 'Milby' of *Scenes from Clerical Life*). See also *Amos Barton*, *Felix Holt*, and *The Mill on the Floss*. Pop. 42,000.

Nuraghe, or NURHAG, the name of round towers, in shape truncated cones, of which 3000 are scattered about the island of Sardinia. They vary from 20 to 60 feet in diameter, rise 30 or 40 feet above the ground, with two or three stories of domed chambers connected by a spiral staircase, and are made of granite, limestone, basalt, porphyry, sandstone, and schist, built in regular courses of roughly-hewn stone, without cement. Some of the stones in the lower courses weigh 12 tons each. Believed to be late Bronze Age fortified dwellings, they closely resemble the tal-yots of Minorca and the Brochs (q.v.) of Scotland.

Nur ed-Din Mahmūd, MALEK AL-ADEL, emir and sultan of Syria, was born at Damascus

in 1117. His father, Omad ed-Din Zenghi, originally governor of Mosul and Diarbekir under the Seljuk sultans, had established his independence, and extended his authority over northern Syria. Nur ed-Din Mahmūd succeeded him in 1145, and changed the seat of government from Mosul to Aleppo. From this time onwards his life was one long duel with the Christians—the Crusaders, Hospitallers, Templars, and Knights of the Latin Kingdom of Jerusalem. The most notable incidents in this contest may be briefly summarised. Count Joscelin, in an attempt to recover his capital, Edessa, was signally discomfited under its walls, and his army almost annihilated. This gave occasion to the second Crusade. The Crusaders were, however, foiled by Nur ed-Din before Damascus, and, being defeated in a number of conflicts, abandoned their enterprise. The emir next conquered Tripolis and Antioch, the prince of the latter territory being defeated and slain in a bloody conflict in June 1149; and before 1151 all the Christian strongholds in Syria were in Nur ed-Din's hands. He next took possession of Damascus (which till this time had been ruled by an independent Seljuk prince) in 1153. About this time a terrible earthquake devastated Syria, levelling large portions of Antioch, Tripolis, Hamath, Hems, and other towns; and Nur ed-Din devoted all his energies to repairing the damage done. In 1157 the Christian orders suffered a severe defeat near Paneas; but an illness which prostrated their enemy in 1159 enabled them to retake some of their lost territories. Recovering, Nur ed-Din soon won back what had been taken from him, and turned his attention to Egypt, then governed by the effeminate and degenerate Fatimites. In 1168 his brother, Asad al-Din Shirkoḥ, overran Egypt, but, dying soon afterwards, was succeeded by his nephew, the celebrated Saladin (q.v.), who completed the conquest of the country, and restored the Sunnite faith. This won for Nur ed-Din the gratitude of the khalif of Bagdad, who created him sultan of Syria and Egypt. Nur ed-Din, however, grew jealous of his able young lieutenant, and was preparing to march into Egypt in person, when he died at Damascus in May 1173. This prince is one of the great heroes of Moslem history. He was not a savage conqueror, but zealously promoted the cultivation of the sciences, arts, and literature, and established a strict administration of justice throughout his dominions; he was revered by his Moslem, and greatly respected by his Christian, subjects.

Nürnberg (English sometimes *Nuremberg*), a city in the Bavarian province of Middle Franconia, in a sandy but well-cultivated district, on the little Pegnitz (a sub-affluent of the Main), 95 miles N. by W. of Munich. It is the quaintest and most interesting town of Germany, on account of the wealth of mediæval architecture which it presents in its many-towered walls, its gateways, its picturesque streets with their gabled house-fronts, its bridges, and its beautiful Gothic fountains. The Burg or palace, built (c. 1024-1158) by Conrad II. and Frederick Barbarossa, commands a glorious view of the surrounding country, and is rich in paintings and wood-carvings. Of eight fine churches the two finest are St Lawrence (1274-1477), with two noble towers 233 feet high, exquisite stained glass, the famous stone tabernacle (1495-1500) by Adam Kraft, and the wood-carvings of Veit Stoss; and St Sebald's (c. 1225-1377), with the superb shrine of Peter Vischer. Other noteworthy objects are the Italian Renaissance town-hall (1622); the law-courts (1877); the gymnasium, founded by Melanchthon (1526); the Germanic museum (1852); an industrial museum (1871); a library; Albrecht Dürer's house; and the statues of him, Hans Sachs, and

Melanchthon, with the 'Victoria' or soldiers' monument (1876). Although the glory of Nürnberg's foreign commerce has long since passed away, the home trade is still of high importance. It includes the specialties of metal, wood, and bone carvings, and children's 'Dutch' toys and dolls, which, known as 'Nuremberg wares,' find a ready sale in every part of Europe, and are largely exported to America and the East. There are numerous factories, producing also machinery, rolling-stock, lead-pencils, beer, &c.; and the town besides does a vast export trade in hops. Pop. (1818) 26,854; (1875) 91,018; (1890) 142,590; (1910) 332,651; (1919) 352,679, mainly Protestants.

Schönbrunnen Fountain, Nürnberg.

First heard of in 1050, Nürnberg was raised to the rank of a free imperial city by Frederick II. in 1219. In 1417 the Hohenzollerns sold all their rights to the magistracy. This put an end to the feuds which had hitherto raged between the burghs and the municipality; and Nürnberg for a time became the chief home in Germany of the arts and of inventions—watches or 'Nuremberg eggs,' air-guns, globes, &c. Simultaneously it grew rich with the fruits of the great commerce which it maintained between the traders of the East and the other European marts. The discovery of the Cape passage to India deprived it of its pre-eminence, and the Thirty Years' War completed the decay of the city, which a century before had embraced the Reformed doctrines. In 1803 it retained its independence, with a territory of 483 sq. m. and 80,000 inhabitants, but in 1806 was transferred to Bavaria.

Nursery Rhymes, metrical jingles transmitted in folklore and mechanically repeated by children at their play, without knowledge of their significance or origin. Being in verse form they are easily preserved, either as mere traditional rhymes, or as formulas to be used in games; and, as unconscious survivals of a remote antiquity, they not infrequently preserve for the scientific inquirer fragments of ancient incantations for healing diseases or revealing the future, and invocations combined with ceremonial observances, while

the intimate nature of the religious conceptions involved points back unmistakably to a mediæval origin. Children with all their inventiveness and imagination are slaves of the letter, and most of their game-formulas are handed down from generation to generation along with the games themselves. In their characteristic directness, point, and quaintness of phrase, they defy imitation, and in their faculty of arresting the imagination from age to age they reveal the instinct of perpetuity. Many of them are beyond doubt survivals among children of May games, ring-songs and dances, rounds, and kissing games which in old England were played by grown-up people, and those of the higher grades of society.

Under the same general head we include nursery rhymes proper, and counting-out rhymes (to decide who shall begin a game), cumulative rhymes, courting and love games, playing at work, flower oracles, and riddle and guessing games; while on the other hand popular mottoes, old saws and maxims relating to husbandry, the weather, or the like, and all the wealth of local rhymes and sayings belong to the popular rhymes of folklore generally. The verses usually consist either of a rhyming couplet, or of four lines in which the second and fourth rhyme; they are often accompanied by a refrain, which may be a single added line, or may be made up of two lines inserted into the stanza; and in place of exact consonance, any assonance, or similarity of sound, will answer for the rhyme.

See FOLKLORE, PROVERBS, SHEEP-SCORING NUMERALS, and RIDDLES; also J. O. Halliwell-Phillips, *Nursery Rhymes of England* (1842; 6th ed. 1860); R. Chambers, *Popular Rhymes of Scotland* (1842); E. Rolland, *Rimes et Jeux de l'Enfance* (Paris, 1883); W. Wells Newell, *Games and Songs of American Children* (new ed. 1903); Lady Gomme, *Traditional Games of Great Britain* (1894-98), *Children's Singing Games* (1904); Haddon, *The Study of Man* (1898); and Miss Eckenstein, *Comparative Studies in Nursery Rhymes* (1906).

Nursing. The nursing of the sick, which has become one of the largest and most important professions open to women, traces its origin from early Greek history. The daughter of Asclepius, who assisted in the rites of the temples in which the diseased were laid, was known as Hygieia. The temple of Hippocrates, the celebrated physician of antiquity, in the island of Cos, was the most famous of all, and the 'oath of Hippocrates' has governed the healing profession to this day, as it has given it its highest ideals. The careful bedside study of disease which he initiated made nursing, i.e. tending and watching the patient, a matter of immense importance. He also realised the absolute necessity for cleanliness, and his advice might stand nurses in good stead even to the present time. In Roman days there is not much to relate of the development of the nurse as apart from the multitude of drug-sellers, bath-attendants, midwives, &c.; it was in the middle ages that the Christian idea of help to the weak and suffering arose, and this was largely undertaken by women through religious orders and associations. There was a great hospital movement in Europe dating from the 12th century, and by the 15th century quite a number of hospitals were established in England. Our great London hospitals, such as St Bartholomew's (1123) and St Thomas's (1215), date from these early days. The work of nursing was one of charity or penance, and there were no technical qualifications needed for the nurse.

It may be said that these conditions obtained until the middle of last century. Certainly at that time nursing had reached a very low ebb. Perhaps Dickens in his picture of the immortal 'Sairey Gamp' did as much as any one to bring home to the nation the depths that it had reached.

Nursing was not a profession; it was hardly an occupation for respectable young women. In the great hospitals the records of the early part of last century continually tell of dismissals for drunkenness and other misdemeanours. Though it was considered desirable that nurses should be able to read and write, this regulation had to be relaxed owing to the difficulty of obtaining nurses. 'We always engage them without a character,' wrote a doctor, 'as no respectable person will undertake so disagreeable an office.'

The movement for a change in their condition proceeded from Germany, though the influence of the great religious revival under Wesley, and the advanced views of the Society of Friends and notably of Elizabeth Fry, had a marked effect upon it in England. In Germany it was even more distinctly religious than it was in England, and it started with a Protestant Order of Deaconesses at Kaiserswerth, under the direction of Pastor Fliedner. Fliedner had come into touch with English philanthropists, and it was at Kaiserswerth that the real reformer of nursing, not only in England, but throughout the civilised world, Florence Nightingale, obtained her training. It was through the immense power and driving-force of this one woman that nursing became what it is—a woman's profession so organised as to be the admiration of every country. Florence Nightingale began her work in a private institution in London, but the breaking out of the Crimean war gave her the chance she longed for of developing nursing on an adequate scale. The British sick and wounded were suffering terribly from neglect, and Sidney Herbert, the Minister for War, took the bold step of sending out Florence Nightingale with a company of women nurses, whom she collected with the greatest possible difficulty. How Miss Nightingale did her work at Scutari and elsewhere, and brought order out of chaos, is known to all the world. She had to act sanitary officer as well as nurse, to improve food and clothing as well as give medical care, and hence 'The Lady with the Lamp' became a power to be reckoned with in ill-conducted departments. The health of the army after the war was her constant care, and it is to her influence that the appointment of a Royal Commission to inquire into army medical affairs was due. She wrote much on the subject, but above all she grasped the idea that preventive work is more important even than curative.

The empire gave her a tribute of £44,000, and this—the 'Nightingale Fund'—was used by her for the training of nurses on lines which she devised, and which have been followed to the present day. The scheme was set on foot at St Thomas's Hospital in London. It was thought a severe one in those days, but from the Nightingale students there went forth high-minded and well-educated women who set the standard in hospitals all over the country. Even workhouse and district nurses became transformed under the new influence.

As regards the present condition of nursing, the training given in our large hospitals is very thorough, is rapidly improving under the influence of increased medical and surgical knowledge, and the improvement has been hastened by the experience gained in the Great War. The definite organisation of the profession has been a matter of great difficulty and controversy. The controversy principally raged over the question of state regulation, which, after many futile private efforts, became law under the newly created Ministry of Health in the year 1919. The profession now has self-government; there is a nursing council for England and Wales and another for Scotland. Of the 25 members of the English council, 16 must be registered nurses elected by persons registered

under the act. There are four supplementary registers for male, mental, fever, and sick children's nurses, as well as the general register, and the council regulates the admission to, and the removal from, the register, and it also has to deal with training and examination. There is a college of nursing, which is established as a centre for every sort of nursing activity, and as a body which may help on nursing education in many directions.

Of recent years considerable advance has been made as to increase of pay and reduction of hours of work, but in both these matters much remains to be done. The usual course of general training is now four years, or a minimum of three years before a certificate is given. The endeavour is made to make this general training as comprehensive as possible. Most large hospitals have sister-tutors, specially appointed to give instruction, and all have courses of lectures for the probationers and nurses, followed by examinations. Nurses usually enter on their work in general hospitals about the age of 21. There is also post-graduate teaching in many hospitals. Trained nurses may qualify in some hospitals for the certificate of the Central Midwives Board, in massage and in venereal diseases, as well as in mothercraft. At King's College in London there is a course for trained nurses who aim at becoming tutor-nurses.

Nursing on the Continent has not developed on such thorough lines as in Britain, but it has made great strides in America and in our oversea dominions. In the United States, Teachers College, Columbia University, makes elaborate provision for graduate nurses preparing for special branches of nursing work, and most of the students are working for their bachelor's or master's degree. The effort is made to take a girl straight from school and give her a good general education before she enters on her professional hospital training. The importance of a nurse's work to the state is fully realised in America.

As regards the types of nursing work, they are numerous. There are *district nurses* now to be found in most districts or parishes, who are frequently 'Queen's nurses,' i.e. nurses who have received their ordinary training and, later on, special district training. These nurses are supported locally, and if they do child-welfare or tuberculosis work, they have to qualify specially as health visitors. For child-welfare work the certificate of the Central Midwives Board is required. *Poor law work* has greatly improved in recent years. Excellent training is given in the large poor law infirmaries, but in the small workhouses there is still something to be desired. *Public health nursing* is required in different directions. Besides the county, city, or borough schemes for tuberculosis visiting, &c., the education authorities employ a large number of nurses for dealing with children who have been medically inspected, and whose cases require following up. Fever and isolation hospital cases come under this category, and the course for fever training lasts for two years, possibly being taken before general training begins. *Private nursing* is carried on either from a hospital which sends out its certificated nurses or from an institution, 'co-operation,' or home. There are not many independent nurses, but some visit by the day. Nurses in private nursing homes vary in quality. *Sick children nurses*.—The admission to this part of the register, containing the names of registered sick children nurses, entails their having been trained in a general hospital for children for three years. *Mental nursing*.—For mental nursing there is a three-years' course in a recognised institution for the treatment of mental disorders, and a certificate is granted by the Medico-Psychological Association. Nurses are of both sexes, but

women are being increasingly made use of. Excepting for mental work, there are few male nurses now employed.

There is a Colonial Nursing Association which sends trained nurses to crown colonies and small British communities in foreign countries; and also an Indian Nursing Association which provides trained nurses for Europeans in India.

Army Nursing.—Queen Alexandra's Imperial Military Nursing Service originated in 1902. It has a matron-in-chief at its head, and principal matron, matrons, sisters, and staff under her. There is also a Reserve Service, which in peace time is small, but during the European War it increased to over ten thousand. There is likewise a Territorial Force Nursing Service, which was established in 1907 in connection with the Territorial Army. It is a volunteer and in peace an unpaid service, but was called up along with the Territorial Force in 1914, and by the end of the war its numbers reached 8000. The work of army nursing was assisted by members of Voluntary Aid Detachments (see RED CROSS), two V.A.D. members taking the place of one trained nurse. *Queen Alexandra's Royal Naval Service* is a small one, which serves mainly on land in naval hospitals. The *Royal Air Force Nursing Service* has recently been established, and its nurses mainly serve abroad.

See M. Adelaide Nutting and Lavinia L. Dock, *A History of Nursing* (4 vols. 1921); Sarah Tooley, *History of Nursing in the British Empire* (1906); Sir Edward Cook, *The Life of Florence Nightingale* (2 vols. 1914); Sir Henry Burdett, *The Nursing Profession* (1915), *The Science and Art of Nursing* (4 vols. 1908); E. S. Haldane, *The British Nurse in Peace and War* (1923).

Nut, in popular language, is the name given to all those fruits which have the seed enclosed in a bony, woody, or leathery pericarp, not opening when ripe. Amongst the best-known and most valuable nuts are the Hazel-nut, Brazil-nut, Walnut, Chestnut, and Coconut, all of which are edible. Other nuts are used in medicine and the arts. Some of the edible nuts abound in a bland oil, which is used for cooking, and 'nut-butter.'—In Botany the term nut (*nux*) is used to designate a one-celled fruit, with a hardened pericarp, containing, when mature, only one seed. The Achene (q.v.) was by the older botanists generally included in this term.

Nutation is a slight oscillatory movement of the earth's axis which disturbs the otherwise circular path described by the pole of the earth round that of the ecliptic, known as the 'precession of the equinoxes.' It is produced by the same causes—viz. the attraction of the sun, moon, and planets (the attraction of the last mentioned being so small as to be quite imperceptible) upon the bulging zone

about the earth's equator, though in this case it is the moon alone that is the effective agent. It also, for reasons which need not be given here, depends, for the most part, not upon the position of the moon in her orbit, but of the moon's node. If there was no precession of the equinoxes nutation would
